It is impossible within the necessary limits of this paper to do more than outline the main features of this subject. The details, if more minutely followed, would occupy altogether more time and space than are at my present disposal. It may, however, be stated in conclusion, that the careful adjustment of the foregoing ration to the daily life of the diabetic patient with comfort and complete toleration, in accordance with the principles laid down, so as to maintain a perfect balance of metabolism, constitutes the highest skill attainable in the dietetic treatment of diabetes. It also probably marks the present zenith line of our dietetic resources in this disease.

SUGGESTIONS ON THE LIMITATIONS AND TREATMENT OF JUVENILE CRIMINALS.

Presented to the Section on State Medicine at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY DANIEL R. BROWER, A.M., M.D., LL.D.

Professor of Mental Diseases, Materia Medica and Therapeutics, Rush Medical College; Professor of Nervous Diseases Woman's Medical College, Northwestern University.
CHICAGO, ILL.

The growth of the criminal class is nearly three times greater than the growth of the population. Such is a reasonable deduction from the publication of the Eleventh Census of the United States, and this blot on our civilization demands treatment.

It is a great question—one that can not be settled by the courts and the church. It contains within it many problems that can only be solved by the wise physician. Crime has a physical basis; biologic conditions are directly and indirectly important factors in determining human action. Conditions more or less pathologic exercise a most important rôle in the production of crime. It requires but a glance at the inmates of a reformatory or penitentiary to satisfy oneself that criminals are physically inferior, exhibiting on every side stigmata of degeneracy. They have features that differentiate them from their more fortunate brethren. They come into the world—at least 30 per cent. of them—with an inheritance that they could no more overcome than they could the course of the sun, and, combined with this vicious inheritance, there has been a no less bad development in the midst of ignorance, poverty, and crime. Our jails are the nurseries of crime. The juvenile offenders here receive valuable lessons in crime; how to do it most skillfully and with the least danger of detection; and when their time of release comes they go out much better equipped to follow their occupation successfully.

Morrison, in his admirable work on "Juvenile Offenders," establishes, beyond contradiction, the following four important propositions: 1, that the death-rate among juvenile offenders is higher than among the general population; 2, that they have sprung from short-lived parents; 3, that their average stature is three to four inches lower, and their weight 30 per cent. less than children of the same age in the general population; 4, that their mental capacity is much below normal. These propositions establish the fact that the juvenile offenders are degenerates, and, if so, the repressive agencies in the shape of

prisons and police are altogether inadequate to cure them.

In order to limit those criminals, society must stop their propagation. Dougdale found in the "Juke" family 1,200 criminals and paupers as the output of one vicious ancestor in seven generations. McCulloch found 1,750 criminals and paupers in six generations as the progeny of "Ben Ishmael," and these cases are by no means exceptional. We must have, therefore, laws regulating marriages, and, in formulating such laws, we must remember the close relation between alcoholism, other forms of inebriety, venereal diseases, and degeneracy. We must, however, bear in mind the fact that the subjects of insanity, epilepsy, and tuberculosis are all alike accompanied by such marked involvement of the nervous system that their progeny are usually inferior physically, and hence liable to drift into this large and rapidly growing class.

The marriage license, in addition to present requirements, should demand evidence that both parties are in good health, that they are not inebriates, not epileptic, not tuberculous, not insane, not criminals, not paupers, and that they have no active venereal disease. The limitation, moreover, demands that the children of vicious parentage be speedily identified and taken from their bad environments before they become criminals; placed in charge of suitable custodians, to be appointed by the courts; and when properly educated and trained in some useful employment, they be given a reasonable capital with which to begin life, unless it shall be found by competent medical authority that they are incorrigible—and then they should be permanently secluded.

The juvenile criminal should not be placed in a common jail when arrested, for in this nursery of crime his malevolent tendency will simply be more fully developed, and, if he is an accidental transgressor, it is most reprehensible to brand him as a "jail bird," for, with this added stigma, his reformation will be made more difficult. Special provision should be made for him while waiting trial, so that the good, rather than evil, that is in him may be developed. If convicted, he should be sent to a reform school, where his physical, normal, and intellectual powers will receive proper development, where he will be taught some useful occupation that will, in after life, give him a reasonable means of livelihood; where he will receive such attention from a physician versed in criminal anthropology as his condition requires, and who will assist ultimately in determining the question of his curability, or incorrigibility. When he has been cured, he should be discharged and given a reasonable sum of money, as a capital with which to maintain himself until he can make a start in his legitimate life work. This scheme for the treatment of juvenile offenders is no dream, but is a realization in "Darkest Russia."

This plan is now, and has been, in successful use for many years in Moscow, and our reformatories at Pontiac, Ill., and Elmira, N.Y., are steps in the same direction. The treatment of criminals is just as illogical today as was the treatment of the insane one hundred years ago, and the reform must come through the beneficent influence of the self-sacrificing and philanthropic members of this great medical association.

Let us have a Department of Public Health!

STATE REGULATION OF MARRIAGE FOR THE PREVENTION OF COMMUNICABLE AND HEREDITARY DISEASES.

Presented to the Section on State Medicine at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY ALBERT H. BURR, PH.D., M.D.

ADJUNCT PROFESSOR PRACTICE OF MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS; ATTENDING PHYSICIAN TO PROVIDENT HOSPITAL. CHICAGO.

Society as constituted under whatever form of government is more or less incomplete in its organization. Evolution, here as elsewhere, is working out the destiny of social affairs. New sociologic problems arise with every advance in our commercial relations, our manufacturing interests and our knowledge of the useful arts and sciences. Especially is this true as it relates to the causes and prevention of diseases. A fundamental principle, recognized by the earliest patriarchial, tribal and feudal forms of society, up to the highest development of representative governments, is the right of the individual to protection against physical harm from his enemies. It is only an elaboration of this principle which makes it the business of the State to do for the mass of individuals, for the good of society, what can not be done or so well done by the individuals themselves.

In return for this protection and share in the general prosperity of the whole, the individual is called upon to make many personal sacrifices. He must "keep off the grass," *pro bono publico*, in many localities as he travels through the experiences of life. Although their operations may work hardships at times to particular individuals, nevertheless sanitary, hygienic and quarantine regulations for the protection of the public health are widely acknowledged to be measures of the highest wisdom. The public is easily aroused to the dangers of epidemics like cholera, yellow fever and smallpox, and submits to wise regulations for the prevention or stamping out of these fearful scourges. The sudden onset, rapid spread and swift destruction to life invest these diseases with a tragic interest that on occasion alarms the public, paralyzes local industry and commerce, and engages public attention often beyond the gravity of the situation. No expenditure of means or measures is counted too great on the part of governments in order to protect their subjects from such diseases. Happily, the frequency and force of these scourges have been greatly reduced in civilized countries, for they have been almost shorn of their terrors through vaccination, quarantine and hygienic regulations.

Alive to these great dangers, as we should be, vigilant for their suppression with the financial, legislative and executive resources of the State, as we are, what is our attitude toward other infectious diseases, whose sources are equally well or better known, and whose methods of contamination are constantly demonstrated on every hand—diseases whose endemic presence is perennial, whose ravages are greater because of their constant, silent and concealed operations? If the epidemics we have just mentioned may slay their hundreds or thousands on occasional outbreaks, the preventable diseases like gonorrhea, syphilis and tuberculosis are slaying annually their hundreds of thousands. The State is opposing the ravages of this class of diseases with feeble barriers, or none at all. The public is obtuse and indifferent, because their devastations are not matters of sensa-

tional newspaper reports and do not come with the tragic effect of sudden onset and swift destruction. The masses are ignorant concerning the gravity of these diseases, or any adequate means of limiting or preventing their transmission.

Every measure in this direction which is wise in its provisions should have the hearty support of the medical profession. Indeed, it is through our profession alone that a knowledge of the extent and ravages of these diseases can be imparted and means for their prevention pointed out. In this paper we wish to discuss but one of many prophylactic measures which we believe would prevent much injury and death, and would protect many innocent wives and children who suffer most cruelly from communicable diseases by direct contact or by heredity.

We earnestly advocate more stringent laws regulating matrimony. We believe the public good demands that every candidate presenting himself or herself for license to marry should be required to file a certificate of health from a legally qualified examining physician, showing freedom from hereditary diseases, like insanity or epilepsy, from all active tubercular infections, and from communicable venereal diseases.

All individuals entering the bonds of wedlock have a right to know that their own bodies shall not be contaminated through this relation by reason of already existing disease or taint. They have a right to know that their progeny shall not be the victims of hereditary diseases or direct contamination from the same source. Every child has the inalienable right to be well-born, at least, if not born a thoroughbred. Who can safeguard these rights but the State? In these days of physical degeneracy among the highly civilized nations matrimony is governed more by questions of mere sentiment, finance or expediency than by a consideration of physical, mental or moral fitness. If in human breeding we ignore the simplest rules of those who breed physical perfection in horses, cattle, pigs and poultry, it should, at any rate, be obligatory on the part of the State, to protect the lives and health of those who are helpless to protect themselves. The least it can do is to prevent the diseased from contaminating the healthy and innocent through the license to marry.

Legal restrictions placed on our statute books with this end in view would work hardship to no one who has a moral right to marry. Such legislation would be of immense benefit as a means of public education concerning the prevalence of these dangerous maladies and the frequency of their distribution to innocent, unsuspecting wives and their helpless babes. They would become topics for discussion in every home where a marriage was prospective. The public would very soon inquire into the reasons for such legislation. It would learn the truths concerning evils which the profession knows full well, but upon which it is powerless to give public instruction, and against which, unaided by law, it is powerless to enforce protective measures.

The laity would soon come to know what Noeggerath and Ricord taught many years ago: that the majority of all males become gonorrheic usually *before* matrimony, and that a large proportion of these remain in uncured chronic or latent stages for indefinite periods, during which they can impart this dangerous disease to others; that 10 to 30 per cent. of all females become gonorrheic usually *after* matrimony, and that the results are usually of much graver

importance to women than to men; that gonorrhea is accountable for most of women's pelvic woes; that it is the greatest cause of sterility in both sexes (Keherer); that it is the greatest single cause of blindness—18.5 to 23.5 per cent. of all the blind in early life being from this cause alone (Magnus, Fuchs and Lucius Howe); that it often kills and that from this cause alone a license to marry may also prove a death-warrant to a confiding bride. The laity would soon come to know that syphilis, of all diseases, is the greatest cause of abortion; that one-third of all syphilitic pregnancies abort or are still-born; that one-third of those born alive die during the first six months (Carpenter and Grassowitz); that the remainder are more or less enfeebled, deformed or short-lived through lowered vital resistance; that locomotor ataxia and certain forms of insanity are almost synonymous with so-called tertiary syphilis. The laity would soon come to know that the great white plague of consumption is the king of death among all diseases, cutting down from one-seventh to one-ninth of the human race; that it is propagated through the marriage of tuberculous individuals; that the progeny of such inherit weak constitutions and a marked tendency to contract the same disease. The laity would soon come to know that persons tainted by mental and nervous derangements, like insanity, chronic alcoholism, dipsomania and epilepsy, are very liable to beget a progeny of physical, mental and moral degenerates through a license to marry. It would learn that all these classes of diseases thrust upon the State a great burden of caring for the diseased, the defectives and the criminals that largely fill our asylums, poorhouses and jails; that the State has not only the right to protect the immediate interests of the individual, but its own interests also by preventing the marriage of those who might be inimical to private and public welfare.

With such widespread knowledge a strong conviction would prevail that the diseased and defectives have no business to marry. It would be regarded as a crime for these classes of individuals to marry, and the demand would be imperative on the part of the public that effective, discriminating laws regarding license to marry must be enforced for the public good.

The vital importance of matrimony to organized society makes it obligatory on the part of the State to impose few barriers to its free exercise. "Matrimony is the restraining power which keeps society decent, to say nothing of the higher blessings which flow from it." (Bishop.) Again, Ayliffe declares, "As the first cause and reason of matrimony ought to be the design of having offspring, so the second reason ought to be the avoidance of fornication." Manifestly the largest exercise of the institution of marriage—so essential to the highest good of society—should be encouraged between all persons qualified for this duty. But it seems to us equally evident that the State is under just as strong obligations to protect its subjects from the dangers of communicable and hereditary diseases on entering marriage, by requiring candidates to pass efficient medical inspection before granting to them the privileges and responsibilities of this important civil relation.

So far, restrictions against marriage in the United States have been confined to questions concerning minority, consanguinity and micidegenation. Attempts have been made to pass bills in some States to regulate the granting of marriage licenses with respect to

the prevention of disease. None have become statutory law so far as we have been able to learn.

Having shown conclusively, as we believe, the urgent need of wise legislation in this matter, the following working model of a bill is submitted by the author, for the drafting of which he is largely indebted to Dr. Frank W. Reilly, assistant health commissioner of Chicago, whose ripe judgment and experience in securing medical and sanitary legislation, and whose long connection with the Illinois State Board of Health eminently qualifies him to pass upon what may reasonably be expected of legislators in this connection. While this bill does not cover all that has been set forth as desirable, it involves the more important considerations, and if attainable will mark an advance which, let us hope, with enlightened public sentiment, may yet reach the higher ideals outlined in this paper:

A BILL

FOR AN ACT TO REVISE THE LAW IN RELATION TO MARRIAGE.

SECTION 1.—*Be it enacted*, by the . . . of the State of . . . That it shall hereafter be unlawful to issue a license to marry to any applicant for such license who fails to present with his application a certificate, as hereinafter provided, setting forth that the applicant is not the subject of acute or latent gonorrhea, or syphilis in the communicable stages.

SEC. 2.—The certificate required shall be accepted from any reputable physician who is a member in good standing of the National, State, County, City or other similar recognized medical organization of the school of practice to which he or she belongs, and shall be in form and substance as follows, to-wit:

State of . . . }
County of . . . }
I, . . . M.D., a legally qualified physician and member in good standing of the . . . whereof . . . M.D., (Address . . .) is Secretary, do hereby certify that I have examined . . . resident of . . . an intending applicant for license to marry, and that my examination, made with due skill and thoroughness, and during a sufficient period of time, fully satisfied my professional judgment that said intending applicant is not the subject of any of the disqualifications for marriage specified in Sec. 1 of the Act to revise the law in relation to marriages, approved . . . 189 . . . in force . . . 189 . . .

I do, hereby, further certify that this certificate is given with a full realization of the sufferings entailed upon wives and offspring by marriages with the subjects of said disqualifications.

Witness my hand this . . . day of . . . 189 . . .
. . . M.D. Address . . .

SEC. 3.—The physician's certificate shall be dealt with in the same manner, as to registry, endorsement and preservation, as is now prescribed for the certificate of marriage.

SEC. 4.—All acts or parts of acts inconsistent, or in conflict, with this act are hereby repealed, and this act shall take effect and be in force from and after its passage.

ARTIFICIAL RESPIRATION IN RELATION TO STATE MEDICINE.

Presented to the Section on State Medicine, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY EDWARD DAVIES McDANIEL, A.M., MD., LL.D.

MOBILE, ALA.

The purpose of State medicine is the protection of the life of aggregated man from injury and death. This purpose is mainly accomplished by protection from the causes of injury and death by preventing, avoiding or removing such causes and mitigating or curing their effects. As the whole must always include all its parts, so aggregated, nationalized, communized man must include its every constituent individual, and state medicine in its mission must embrace the warding off from each and every individual the causes that may imperil, impair or destroy the life of that individual. Life need not here be defined. Its existence is postulated. It is equally known that life exists in two states—the *latent* and the *manifest*. The latent is a dormant, germinal, quasi-hibernant state, with a capacity of being developed or aroused under proper influences into the manifest state char-

acterized by a display of definite aggregated and correlated processes and phenomena. These processes and phenomena, once developed, become the characteristic properties of life, the manifestations by and through which alone its existence is known and revealed to us. What these processes and manifestations are need not be here mentioned in detail, since they were enumerated in a paper entitled "The Relation of Physiologic Principles to Artificial Respiration," presented to the Section on Physiology and Dietetics, at the meeting in Philadelphia, Pa., June 4, 1897, and since published in the JOURNAL. In the same paper may be found enumerated the leading conditions of depressed life with their causes and treatment. As the leading process of human life after birth is respiration, so the leading measure for restoring life from dangerously interrupted or prolonged depressed conditions is artificial respiration with its appropriate preparations and adjuvants.

Connected with the value and importance of artificial respiration to State medicine, a very interesting practical and important question presents itself, viz.: How long may respiration be interrupted, suppressed or in abeyance and yet a reasonable hope of its restoration still be entertained?

From the most reliable sources of information at command, and covering the period of sixty years are presented the following statements:

Tanner, in his "Clinical Medicine," says: "Death is said to be the result where breathing is interrupted for any more than *three minutes*."

In a report of a committee of the Royal Humane Society of Great Britain with the very distinguished Sir Benjamin Brodie for chairman, in 1840, it is stated that "It is the opinion of the medical members of the committee, that the period, in cases of asphyxia, when artificial respiration might be successful is *very short and scarcely more than momentary*." In 1744 there was published, in Edinburg, a case of a man apparently dead from suffocation in a coal mine. "Mr. Topack used insufflation, mouth to mouth, bled him, caused him to be pushed, pulled and rubbed, as much as he could for *about an hour* when he *began* to come to himself." In the *Medical Gazette* (English), quoted by Dr. Howard of Baltimore, Md., Mr. Terry of Northampton gives "two cases of still-birth in which after nearly two hours he succeeded by breathing into the nostril and alternately compressing the chest." Dr. Howard also gives a case of three days' labor, in a primipara, in which a seven months' fetus was expelled *with every sign of life absent*. After the application of conjoined methods of artificial respiration for about *twenty minutes*, the child *began* to breathe. The cord was then cut and perfect health continued. Another case is given—one of a man who fell from a Staten Island steamboat. "About *twenty minutes* after the man fell from the bulwark rail into the bay, the boat backed and the man was hauled on deck *with no sign of life remaining*. Artificial respiration was commenced and in *about ten minutes* the patient gave a short gasp. The treatment was continued and in *about ten minutes more* he breathed naturally and exhibited consciousness." In this case you observe it was *thirty minutes* from the arrest of breathing to the inception of its return as indicated by the short gasp, and *forty minutes* to its full restoration.

Dr. Hamilton of Falkirk, in the *Monthly Journal of Medicine*, May, 1855, reported the following case, which proves that many infants apparently dead, may

be aroused to manifest life by means of artificial respiration long after the time when the effort is ordinarily abandoned.

About ten minutes before 7 P.M., Mrs. C. was delivered of a large male child. A knee presented, and to effect delivery considerable force was required. Even before one leg had passed from the vagina, meconium was voided very copiously and when the child was born it showed not the slightest trace of movement or of sensibility. The usual appliances of rubbing the breast with spirits, plunging the body alternately into cold and warm water, etc., were had recourse to, but apparently without effect. As a last resource artificial respiration was employed. In a short time a slight pulsation of the heart became perceptible and gradually increased in strength, but this was the only motion that could be observed. After having continued the artificial respiration for *an hour and a half*, a slight tremulous motion of the abdomen was noticed, which at first seemed to be merely the effect of the heart's motion propagated downward, but which after *another half hour* was distinctly seen to be produced by very weak and rapid respiratory movements. Along with this improvement, the color of the lips, previously somewhat livid, became of a red natural hue. In *three hours* the temperature was good, the pulsation of the heart was strong and the respiratory motions extended to the upper part of the chest.

In the London *Lancet* of Feb. 14, 1846, is an account of a case that occurred to Dr. Mackness of Hastings.

On his arrival the doctor was informed that the labor was over and that it had been over *ten or fifteen minutes*. He broke the membranes of an entire ovum which he found, tied the cord and gave the child to an attendant, when to his surprise he found another ovum, also entire, from which he extracted another infant. Both infants appeared to be still-born, but by inflating the lungs, dashing cold water over their bodies, wiping them dry and having their skins well rubbed, in *about fifteen or twenty minutes*, both showed signs of animation and on exposure to warmth, cried out lustily. In each of these cases an interval of probably *not less than twenty-five nor more than thirty-five minutes* transpired from the complete expulsion of the fetus to the first show of signs of animation.

In Camden, Ala., on Feb. 25, 1859, after a copious blood-letting practised on a primipara to prevent convulsions that were imminent, a large male fetus was very tediously passed through a relatively small and rigid outlet. It was apneic and apparently dead. Heart movements were imperceptible, but there was more firmness in the flesh of the fetus than is usually found in that of the dead. After trial and failure of Hall's ready method, persistent insufflations mouth to mouth, with warm cerebro spinal bath, cold sprinklings and dry frictions, were finally followed, *after twenty or more minutes*, by spasmodic contraction of the fetal hands and then a sudden gasp. Life signs improved gradually and in about an hour from the complete expulsion of the fetus, respiration seemed good, the cord was cut, the child dressed and I, with two other physicians in attendance, withdrew to another room. After a few minutes I was hurriedly summoned back with the alarm that the infant had stopped breathing. Insufflation was again practised with very tardy but ultimate apparently complete success. After again retiring and remaining for some time in the other room, I was called again to the breathless infant. Insufflation again succeeded. Apnea again occurred. More forcible insufflation was applied, and breathing once more returned, but with it there came a straining cough which persisted until a sudden copious rush of blood through the mouth and nose terminated the infant's life, *four hours and twenty minutes* after its expulsion from the mother and only a few seconds after the last insufflation.

It is perhaps fair to say that in Great Britain and the United States the most cautious conservative medical men, though once in accord with those who limit the capacity of life in adults to a compass of from two to four minutes after the cessation of breathing, are now converted to a more liberal creed. It is known that breathing may be voluntarily "held" for varying times, that practice may extend the time considerably; and that pearl divers and expert divers may safely reach *four minutes* or even *more*. Newspaper reports of executions by hanging and physicians legally detailed to witness such executions, agree that the pulse continues to beat for from five

to fifteen or more minutes after the rope stops the breathing, the average being about ten minutes.

We have not time to dwell at more length on cases, details and results, but feel warranted in stating: 1. That the length of time that adults may be apparently breathless and yet susceptible of resuscitation is not definitely fixed—that it doubtless varies greatly in different cases, is greater than it is generally supposed to be—perhaps, in certain cases, much greater. 2. That the length of time that a fetus may, on its first passage from the mother, remain without visible pulmonary respiration and yet continue susceptible of being saved is very much greater than the corresponding time in the adult; that it is probably greater in the premature fetus than in the fetus of full term and that in the premature fetus, when kept warm, the heart may continue to act *four hours or more*, without any connection with the mother and without visible pulmonary respiration.

It must now be plain to all that such life-saving organizations as go far off on the high seas or great lakes, on the great ships and fleets, or watch out for the lighthouses and mist-covered shore, are not the ones from which State medicine must expect its greatest good and its greatest gain, but contrarywise, the skilful obstetricians, who cease not by day or by night, in summer or winter, in metropolis or in wilderness, on sea or on land, on the mountains and in the vales, in king's houses or in huts, in calm and in storm, to await the coming of helpless, breathless, speechless ones from the home of a lower life to the danger-beset shores of a higher existence—these are they who must ever furnish to State medicine the greatest and best contributions.

How *many* lives may reasonably be expected to be saved to the State by artificial respiration can never be exactly computed; very much must depend upon the safety, certainty and efficiency of the method used; upon the seasonableness and skilfulness with which it is used, and upon emergencies that vary with times, places, events, enterprises, accidents, etc. But a reasonably approximate estimate can be reached when and where conditions approach uniformity. Say that Alabama has a population of two millions and has two thousand physicians, and that each physician annually resuscitates by artificial respiration, mainly, only two cases, not spontaneously recoverable, the number saved in the State will reach four thousand, and at a like rate the saving to the seventy-five million of the United States would amount to one hundred thousand per year.

But in estimating the worth of artificial respiration to the State or to the world the *number* of the lives saved is a far smaller consideration than their *value*. This value can not be comprehended. It can only be thought of in overpowering amazement. The saving of some lives, as those of the insane, the degenerate and the criminal, would be a calamity to the State, but for the warning thus given against the transgression and the occasions furnished for the exhibition and exercise of humanity, of compassion, of beneficence and of justice. But others of those saved, and no doubt most of them, are reserved for higher and nobler destinies. Moses was saved in a frail ark of bulrushes to become the leader, liberator and law-giver of his own oppressed race, and through them of all civilized races. Noah was floated in an ark, from a deep flood to a lofty mountain top, to become the ancestor of races destined to repopulate an inundated, depopulated

world. Alexander Pope was born a weakly, deformed, dwarfed infant. In tender childhood he received, from a vicious cow, injuries from which kindly care restored him; and still later, locked up in a coach that was overturned in a river, he was rescued from otherwise inevitable drowning, by the timely aid of a helping hand. Through such perils, exposures and sufferings was he spared, whose mission it was to translate into English the two greatest epics of Greece and Rome, and otherwise wonderfully to enrich that ever expanding language which many of us now proudly claim as our glorious vernacular. Isaac Newton, when born, was small enough to be placed in a quart cup, yet that diminutive body contained the germ of that wonderful genius who discovered, explained and applied to countless uses and purposes the great law of universal gravitation; who invented and largely developed some of the highest departments and best methods of modern mathematics, and who gave the first great impulse and start to the study and knowledge of light—that great agent that ceaselessly sheds and will shed its bright, beautifying, life-exciting influence through infinite space, boundless stretches and infinite duration's endless years.

Thus to those snatched from the dark valley of the shadow of death by life-saving measures, and especially to the multitudes of apneic infants recoverable only by the aid of artificial respiration and to the descendants of such, the State, through all coming ages, may reasonably look for many of her greatest, brightest, best and most valuable citizens—her astronomers, navigators, discoverers, inventors, educators, patriots, evangelists, prophets, apostles and redeemers.

THE ADMINISTRATION OF SANITARY LAWS.

Presented to the Section on State Medicine, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY WM. P. MUNN, M.D.

COMMISSIONER OF HEALTH,
DENVER, COLO.

The complicated relations existing in most municipal governments between the different departments and bureaus seem to make it essential that the health department, bureau or board should have a legal advisor of its own. Take, for example, a city in which, as in Denver, the boards and officers comprising the various divisions and sub-divisions of the executive force are appointed by different officers, and own no allegiance to a single and responsible head. It can readily be seen how it happens, as it often does, that one department seeks to carry out a plan of action, which in some particulars will conflict with the regulations and activities of another department, and there is no ready method of harmonizing and unifying the efforts of the departments. For example, in most, and perhaps in all cities, the construction of sanitary sewers, or of a waterworks system would devolve upon the officers having charge of public works. Having a regard for other essential matters than sanitary features such an officer may go on and construct a sewer system or waterworks in such a manner as to jeopardize the sanitary interests of the community. The responsible officer of health may not be apprised of what is in contemplation, or he may learn of it in some round-about way. But unless he is consulted

and can give the matter the full attention that it deserves from his point of view, conditions may be brought into existence which he may subsequently find it necessary to remedy but will not have the power to act upon.

Under such circumstances a legal adviser who has given especial attention to the right of the sanitary or health board may keep the health officer advised of his opportunities and his duties, and enable him to accomplish much good for the community both before, during and subsequent to the construction of municipal improvements. I take it that such a special counsel would advise the health officer when he can effectually make his objection and formulate his protest against "public improvement" measures that are unsanitary. But in instances where one counsel acts for all city officers, the city attorney is much more likely to look at matters simply from the standpoint of the board that desires to hasten work along and will so frame their advertisements, phrase their stipulations and arrange their contracts that objections made from a sanitary standpoint will not be properly presented, or when considered will not be agreed to.

Let us consider, for example, a proposed system of water-supply for a city. An intelligent head of a public works department would be largely guided by the results of thorough investigations of health officers in determining whether a certain source was, or was not, free from objection. But an unintelligent works official would probably have, under the laws of most cities, a right to proceed without consulting his health officer, and in no instance do I know of any city where the works department is required by law to comply with the recommendations of the health officer upon this important subject.

A majority of cities are sewered by the combined system, and communities must wait until their growth has reached such a point as to enable them to incur the expense of a combined storm and sanitary sewer system before ordinary sanitary drainage can be provided for. This fact accounts for the long existence of the privy pit and cesspool nuisance in cities. The intelligent health officer, backed or assisted by an attorney who is retained by the sanitary officer alone, will be enabled to have separate sanitary sewer systems constructed early in the growth of a city. Thus the sanitary sewer will be laid before a district is closely built up and before many privies or cesspools have been constructed. New residences going up in the completed sewer district can then be required to at once connect with the sewer, and the soil of the city will never be given an opportunity to become saturated with filth and disease-producing materials. This is simply a preliminary point, however. The relation of the sanitary administration to the administration or alleged administration of justice in any community, is a matter of vital import to the earnest health officer.

Prior to bringing any case in court it is the business of the health office to exhaust every effort to persuade the offending citizen to comply with the regulations. It is an old saying that more flies can be caught by sugar than by vinegar. Apply the principle of that wise saw to the enforcement of sanitary regulations. One person can be influenced by an appeal to his reason, another by an appeal to his pride, either in his own property or in the general neighborhood in which he lives; others are led to comply with orders by showing them how much more

desirable their property can be made from a financial or earning standpoint; others can be cajoled into doing a thing in a certain time which they absolutely refuse to do at the immediate date of the order. But when these classes are exhausted there remain two others that must eventually be brought into court. There is the man who thinks he can always beg off and that you will never carry out the threat of court procedures, and there is the man who is a born fighter and will not yield until he has gone through all the courts. Men of the first sub-class usually come into court when summoned and promise to proceed immediately if no penalty is imposed. It may be well to allow them to go without a fine, but in every instance they should be made to pay the costs. Then if the court is a fairly intelligent friend of sanitary measures he should be asked to warn the offender that the next failure to comply with orders will be punished by a full fine. This promise, if made, should be kept.

In dealing with the class which includes the persistent and obstinate fighter, it is well for the health officer to exhaust every peaceful method before going into court. When it is finally determined that prosecution is necessary it is wise to have the preparations made therefor with the greatest care and under the direct instructions of the attorney who will prosecute the case. First, second and third notices should be carefully drawn up in accord with the strictest technical requirements of the law; the exact manner of enactment of the regulation or ordinance should be looked up so as to assure yourself that it has been lawfully adopted; it should be possible to produce the original act, ordinance or regulation in court if a demand is made for its exhibition; copies of the notices as served should be substantiated by more than one witness; the ownership or control of the property in question should be fully established and not taken upon hearsay; the case should, if possible, not rest solely upon the testimony of employees of the sanitary service, but other citizens should be called to substantiate their evidence; a nuisance should be proven by citizens and by a recital of conditions which will satisfy the court, not by the simple statement or order that "such a thing or condition is a nuisance." It has been my experience that judges of minor courts are more ready to accept common-sense definitions, and to brush aside mere technical objections, than are the judges of superior courts. It has also been my experience that it is easier to win a case before a jury in a district or common pleas court than it is to win before a judge. In common with many other officers, it has been my lot to lose important cases as well as to win them. A recital of some causes of failure may be of service to others, as the cases themselves have been to me, in pointing out certain defects of procedure that result in the loss of a case.

In a prosecution for the sale of watered milk, in one instance, the proof of sale of any portion of the milk was carelessly overlooked; its possession, its carriage and its delivery were proven, but not its sale. The case was dismissed for lack of proof, although the guilt of the accused was morally certain both to the judge and myself. In a prosecution for maintaining a nuisance in the shape of a privy vault in a completed-sewer district, action was brought by an attorney unfamiliar with the ordinances under one section which prohibited such vaults in completed-sewer districts as nuisances, but the substantial proof

that the particular vault was a nuisance was not presented and the case was therefore dismissed. In a prosecution for selling impure ice the party was convicted in the police magistrate's court. From this decision and fine he appealed to the county court, where he was again convicted by a jury. In order to hasten matters and avoid long drawn-out litigation an order was then issued, after a hearing, that the complained-of ice would be destroyed if brought into the city for sale. Upon this the culprit managed to have three judges of different courts intervene with orders and injunctions preventing not only the destruction of the ice, but further prosecutions under the ordinance which had secured his previous convictions. These orders were based upon perjured statements of the attorney that no hearing had been given; inasmuch as the previous hearings were not of record, the falsehood could not be disproved, the uninformed judges of appeals made a ridiculous decision to the effect that "a health commissioner had no right to issue an order to destroy property." All of which may be good law but is bad reasoning from the standpoint of a common-sense sanitarian. Judges are not well informed upon matters relating to sanitation which come before them for decision. Worse than this is the fact that from the peculiar bent of mind acquired by long legal training, they seem to have reached a point where they hold that no other consideration is of quite so much importance as the preservation of alleged property rights, even when such alleged rights violate the inherent right of the people to live out their individual lives. It is my firm impression that sanitary laws can never be properly enforced until a more rigorous method of putting intelligent and conscientious men upon the bench can be devised.

MELANCHOLIA.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY FRANK PARSONS NORBURY, M.D.

Lecturer on Psycho-Physics Illinois College; Neurologist to Our Savior's Hospital; Physician to Oak Lawn Retreat.

JACKSONVILLE, ILL.

The physiologic doctrine of the physical basis of mind is now established beyond dispute, although some of the ardent philosophers of the Platonic school still regard mind as an entity, and view it and consider it apart from its habitat—the brain.

This change in physiologic views has been brought about by the advent of physical methods of inquiry, which, under the name of the new psychology, promises to give us a substantial and real basis from which we may proceed in our excursion into the labyrinth of reason. The bearings of psycho-physics upon the study of mind, together with the empiric observations of the past ages, demonstrate that physiologic laws underlie mental phenomena—that mind reposes upon a nervous property sustained, like every other physical power, by nutrition. It shows, further, that the plasticity of the mind may be impaired in its full functioning by innutrition or malnutrition as well as from undue exercise or its reverse—inaction. Again, we have learned that mind, physiologically considered, is dependent upon bodily conditions for its full powers. Bain, in his excellent work on "Education as a Science," in 1878, expressed this one physiologic circumstance in particular in the following words:

"The human body is a great aggregate of organs or interests—digestion, respiration, muscles, senses, brain. When fatigue overtakes it, the organs generally suffer; when renovation has set in, the organs are generally invigorated. This is the first and most obvious consequence, and therefore, in order to increase the plastic property of the mind you must nourish the body."

We who have studied the phenomena of the mind from the standpoint of disease will recognize the physical basis of mind, and to us mind is the consequence of a long line of new nervous growths—the morphologic development of the senses, the intellect, the emotions and the will. The nervous system is the instrument of the mind—this is the belief which the new psychology has demonstrated to be true. Herbert Spencer, before the advent of the new psycho-physics, said; "The evidence, though so indirect, is so extensive, so varied and so congruous, that we may accept the conclusion without hesitation." Now, the phenomena of the nervous system, viz., its mechanism, functions and condition of action, etc., are purely physical phenomena, controlled by physical or physiologic laws, just the same as are the processes of digestion, circulation, etc. Mind, too, is controlled by physical laws, for while we can not demonstrate the substance of mind, in fact, as Weir Mitchell expresses it: "Indeed, we are as yet uncertain as to where within the skull is the nerve matter with which we think or imagine." ("Clinical Lessons in Nerve Disease.") However, it is to be presumed that mind is identical with other evidences of nervous phenomena, as it is closely associated with nervous change.

In my classes, I have taught that mind is made up of an association of feelings—a confederation of units of feelings. This is in line with the teachings of pathology, as our science of cerebral localization demonstrates. Again, it is in keeping with the teachings of the cellular pathology of Virchow, and with the modern concept of the neuron theory.

In the clinical study of mind it has long been recognized that proper nutrition of the brain is the prime essential of recovery. Especially is this true in melancholia, which, viewed in the light of modern neuropathology, in my judgment, gives us a physical basis from which to consider this disease as a nutritive disorder, of which the mental symptoms play the title rôle, while the accompanying physical symptoms are none the less important, though more or less obscured by the greater conspicuity of disordered mind. The mental phenomena should not be regarded as the disease, any more than the sugar in the urine should be considered as the disease, diabetes. Even the transitory or periodical forms of melancholia, some of which are spoken of by Weir Mitchell, I believe, are the results of innutrition and when we know more of neuron metabolism we will have their physical basis known.

Barker of Johns Hopkins has contributed a most excellent series of papers in the study of the neuron (*New York Medical Journal*), and in a recent paper says, in regard to the laws underlying neuron metabolism, that they are just as fixed and constant as are those of astronomy and botany, and he can conceive of a knowledge of their nature and action which would enable one possessed of it to prophesy unerringly of the functional manifestations of a nervous system made of a given set of neurons, which must result

upon exposure to a given environment. Further, he says: "The neurologist has already learned that in the nervous system certain causes produce certain definite effects, almost with mathematical accuracy, and this fact should encourage him to further research with the hope that the intricate laws in question may gradually be rendered less obscure and vague."

Defective metabolism, then, is the foundation of melancholia, and this is further borne out by operation of the impoverished body, the attenuated action of the nerve-currents, the defective blood, and other evidences showing a diminished, weakened, impaired bodily nutrition. The mental alteration is but the result of lowered nutrition of the brain, as the phenomena of conduct, of intellect, of will and of consciousness itself, one and all are dependent upon a high degree of activity in the nerve elements. The adjustment of mind to the material body lies then along the lines of bodily nutrition. Of course, we must consider the hereditary factor, where, because of minute conditions, the natural energy of the mental organization is limited, or is so unstable as to be affected, then because of the lack of nerve or background to counterbalance extraordinary demands on the available energy, we find early exhaustion and consequential mental anarchy. The nerve elements in such a case are essentially weakly-developed or badly nourished, either of which conditions disturbs the organized associations of centers and permits of speedy exhaustion, and loss of power over thought, feeling, conduct and consciousness. The natural motor restraints or inhibitions are impaired or abolished. Thought-circuits are disturbed, broken or so seemingly locked, that in spite of all efforts the patient can not rid himself of the morbid gloom, which such self-centered, grossly exaggerated thought engenders. The true self fights invading insane self and finally gives up the struggle as vain, and soon is swayed by his delusions and imaginings; will is disintegrated and the other ordinary higher psychical impulses encompassed by the darkening and impervious gloom.

To me this picture is one painted by distorted nutrition, more or less aggravated by the inherent factor in the case. Clinically, melancholia is more than Ziehen (*Am. Jour. of Insanity*) states in his trio of etilogic factors, viz.: hereditary taint, stress and mental shock, for malnutrition is decidedly a primary factor more or less prominent in every case, and should be added to make an etilogic quartet.

While it is true that we meet cases of simple melancholia without much physical disorder, yet I regard physical disease as playing more than a subordinate part in the causation of melancholia. And that this physical disease acts, not by virtue of combined emotions of worry, fear, etc., growing out of the disease, as Ziehen would have us believe, but by reason of malnutrition growing out of the physical disease. Herter, in his recent studies of auto-intoxication, has given us the clue to much of this distress. This I know from personal clinical experience, is the cause of mental disease. Take, for example, the cases having diabetes, gout, lithemia or the convalescence from infectious fevers for a background, and we have striking examples of the physical elements in causation.

It has fallen to my lot to meet a number of cases, in consultation, of alleged insanity who were victims simply of the uric acid diathesis, exaggerated to the point of interference with normal metabolism. A case whom I recently saw was sent me for observation

and diagnosis. Careful inquiry and detailed laboratory investigation demonstrated it to be one of lithemia. By observing Haig's dictum, "control the uric acid and you control the mental disease," I sent him home in two weeks, able to resume his work. You all meet with such cases, and I dare say you rejoice in the fact that you are able to speedily return them to their fields of usefulness.

In diabetes there is a psychic element which grows out of the nutritive disorder. The actual psychosis is one of melancholia and hypochondriasis. I have had but four such cases in my practice in the last ten years. Van Noorden (*Twentieth Century Practice*, Vol. ii), remarks in addition to the fact that melancholia may be present in diabetics, that it may be noticed in all grades of severity, from an almost imperceptible degree of hebetude to the most pronounced form of disorder—suicidal and homicidal melancholy aspects being not infrequent.

I will not enlarge upon those nutritive diseases as being factors, as time will not prevent. However, in closing I wish to add that arteriosclerosis is perhaps one of the most frequent factors in the causation of melancholia in patients past the age of 35 years. Again we may meet cases in active business men whose minds are clear and strong, but who are given to dejection, to melancholy and even to acute melancholia. Their disposition shows a tendency to change, and they are easily moved by their emotions. To all external appearances they are well physically, and it is difficult to detect any grave disturbance of nutrition, and yet if such a case should die, say from intercurrent disease, postmortem examination would reveal arteriosclerosis, especially involving the central arteries and perhaps the basilar artery. (It is a fact that the arteries which are exposed to the greatest strain are first affected by the organic change, arteriosclerosis.)

I have met many such cases, and now have under my care a case given to periodic attacks of melancholia marked by delusions, etc., who is a victim to arteriosclerosis involving the kidney and heart as well as the brain. The very nature of arteriosclerosis is such that it induces wide-spread disturbances of nutrition, and while the brain, the kidney or the heart may show the first evidences of disturbed nutrition, it is very probable that ere long the disturbance will be general rather than local. As Meigs says, "Perhaps no one thing is more important for the diagnostician to know than that vascular disease and fibrosis are certain to come in all men if they live to be old enough."

In conclusion then, let me say that:

1. Mind has a physical basis.
2. The brain is the organ of the mind.
3. The activity of the brain is dependent upon its nutrition.
4. When badly nourished, either from poor blood or illy distributed blood, mental depression and melancholia result.
5. Melancholia is a nutritive disorder, characterized by mental symptoms of depression, dejection, delusions, etc., and the physical symptoms of impaired bodily nutrition, which latter symptoms are as essential evidences of disease as the mental irregularities.

DISCUSSION.

Dr. MEYER of New York—The paper suggests to me a few remarks similar to those that I made yesterday with regard to the paper of Dr. Punton. The general impression is natural that we are dealing in melancholia with an entity, just as we have the entity of neurasthenia, with which everybody is familiar. Now, on observation of a large number of admis-

sions (we have had about eight hundred admissions), and from careful examinations during the last eighteen or twenty months, we found a great number of cases which undoubtedly would have, according to the old classification, gone into the group of melancholia; that is to say, in those classifications which are made at the end of the year for purpose of statistics. In our attempts to make a diagnosis the first week or the second week after the admission of the patient, it was naturally our purpose to make a diagnosis which would mean something as to the future of the case, and not simply a general term according as the patient was depressed or not. It was a question as to what possible classes that patient, whom we were at first sight inclined to call a case of melancholia, would belong. While I admit that melancholia is an entity that everyone knows, I myself could not be satisfied with that. It seemed that for our present research it was our absolute duty to try and find out whether, from the appearances and from the symptomatology in the onset and in the first weeks of the disease, we could not make a conclusion as to what form of melancholia we were dealing with and as to what we could expect in the later course of the disease. This line of thought was opened by Goldvon, over thirty years ago; his books have been too difficult to find, it seems, and have been buried under the inclination of the alienist to examine spinal cords and brains and degenerations, instead of attending to psychiatry. The movement has been taken up again by Krebbling, and it now seems fairly certain to me that we have a problem before us about as follows: It seems from the observation of a large number of cases of melancholia, of what everybody would call melancholia, that we are dealing with quite a number of different disease processes. One might instance that disease process which is so difficult to distinguish from neurasthenia and which was yesterday spoken of as having hardly no distinction from neurasthenia. Then melancholia which occurs in the twenties and thirties, and is coming on rarer at intervals during life, perhaps five, six, eight, ten, twenty times, always in individuals with strong hereditary dispositions, and rather distinguished by the fact that the inhibition, which is called one of the cardinal symptoms of melancholia by the German surgeons, is not present there. Then we have melancholias which are undoubtedly general paralysees. Then there are melancholias which belong to the circular insanities, which change into mania, and can be distinguished by the absence of inhibition. The other view, of course, the nutrition view, is a general question, and while it is of great importance in the treatment of the disease, has relatively little to do with this subject.

Dr. LICHTY, Union Springs, N. Y.—A year ago I came to this Section in Philadelphia, and there seemed to be a strong inclination on the part of the members of the Section to refer these cases of melancholia, neurasthenia and hysteria to faults in nutrition, and I went back from that meeting and thought that I would make certain observations from these cases in reference to that, especially in line with the investigations which Haig has made. I must say that I was rather disappointed. I was unable to verify the assertions which Haig has made, as to the examination of the urine and the relation of uric acid to these cases. But one thing has forced itself upon me, and that is that in most of these cases we do find a change in nutrition. It may be that the changes which I found have been rarer because I see the patients earlier. The institution in which I am working does not take any insane cases, but we do take melancholias, and I was impressed with the fact that we find a thick blood—a blood with hemoglobin of 100, 105, 110, and 6,000,000 corpuscles, and also a heavy urine of a high specific gravity. This may be due to the fact that these people were traveling for long distances before reaching the institution, but I have had them drink the same amount of water as they did before they came and the urine remained of high specific gravity. In the stomach contents I would usually find a hyperacidity. Putting these things together, it seems to me that in melancholia especially, and also in hysteria and neurasthenia, there is faulty elimination. The patient has been inactive; he has not been eating properly; he has not been drinking sufficient water; and acting upon this principle, giving the patient employment, putting him out in the open air, having him eat less and food which is more easily assimilated (probably he really takes more food by taking the diet which I give him than the diet which he has heretofore been taking), and by having him take large amounts of plain water I have succeeded in obtaining good results in these cases. I think the paper which was read is in line with what I have found in my experience.

Dr. JOHN PUNTON—I think the subject of melancholia is one that we can well afford to study carefully, and while the disease has been recognized ever since the days of Hippocrates, yet it does seem that there is a great deal for us to learn in

regard to this very common form of insanity. I believe that most forms of insanity are preceded by mental depression; hence, it is certainly the most common of all the varieties of insanity. In addition to that, I believe that it is only curable in its earlier stages. I believe that the cases of melancholia which are out and out cures come under observation soon after the onset of the disease.

The first step in successful treatment is isolation from home. The insane asylum is not the best place for incipient cases of melancholia. The environment of an insane asylum is against the recovery of ordinary cases of melancholia in my judgment. The State should provide for detention hospitals—half way hospitals between the patient's home and the insane asylum. Today the moment we find a melancholiac in ordinary practice, recognizing that we may have at any time suicidal impulse, and recognizing the fact that the patient is irresponsible, we are compelled to send him to the insane asylum. Usually he remains and becomes an incurable case. If we had a detention hospital that patient could be given the benefit of the doubt, for say from one to six months, and you would be giving your patient a chance of recovery.

Dr. RIGGS of St. Paul, Minn.—I consider the discussion of melancholia most important. Melancholia sine delirio is one important form of melancholia that in my judgment should receive especial attention at the hands of the alienist and neurologist. I am firmly of the opinion that melancholia, as all forms of insanity, starts as a perversion of the functional nutrition of the cell. I think that is the starting point of the insane condition. Usually the light form of melancholia is more dangerous, as far as suicidal impulse is concerned, than any other. My experience, however, has been entirely different from that of Dr. Punton. These cases almost invariably get well. If they do not kill themselves before they have an opportunity to get well, they recover. I can not feel as Dr. Punton does in reference to our insane asylums. The gentlemen whom I have the honor to be acquainted with and work with along the line of psychiatry are thoroughly alive to these classes of cases; the kind of treatment; their proper care in the institution; their environment, and everything of the kind. Of course, if it is possible to prevent cases of this character from going to a State institution, because of the false idea that stigma rests upon one therefrom, it is better to do so; but that false feeling should pass away. Insanity is nothing more than typhoid fever; it is simply an expression of a physical state.

Dr. W. J. HERDMAN—Like all nervous diseases which we have been dealing with in their chronic form, with their fixed and irrevocable conditions, the tendency is now to get back to the incipient stages; if we are to make any progress at all in the arresting of this class of disease, we must learn more concerning the incipient changes which take place. That is the line of research in all directions at the present time with reference to the insanities. As has been said by Dr. Riggs, very truly, it is a perverted nutrition at the outset; and I have in my mind now three cases of my own in which that perverted nutrition was apparently due to reflex causes. You all heard yesterday a report of an acute case of melancholia, the picture being typical. There were disorders of the pelvic organs, and these being corrected the case immediately made a satisfactory recovery. My first experience with a case of melancholia of a typical character was in a young woman of 19 years of age. In making that general observation or investigation of the system which has been my custom always with patients, I discovered that she had an imperfect hymen, and that she never had menstruated to outward appearance. Her mother knew that there was something wrong, but no investigation had been made by the attending physician. I found that there was a tumor resulting from the retained discharge, and it had largely dilated the uterus. I of course immediately advised that the contents of the uterine canal be removed, and that was done, gradually of course, and she made a complete and perfect recovery, although up to that time she had had a strong tendency to suicide for three or four months, and they had had to restrain her for some time from casting herself out of the window. She was in a pronounced state of acute typical melancholia, and as far as we could discover that was the only physical cause there was present there, and when that was removed she made a very satisfactory recovery, remaining well ever since. She is now the mother of a family, and has been a perfectly well woman ever since that time.

The other case which I have in mind, due to pelvic irritation, was one in which retreflexion of the uterus was the apparent cause. The woman had borne several children. She became acutely melancholy, and it was necessary to transfer her to an asylum. She became somewhat better, but pronounced symptoms of melancholia persisted. Allison's operation was performed upon her, after careful investigation of her condition in

all respects, and that having been found to be an apparently serious element in her disease, and she recovered, and has remained well ever since. These are the most pronounced in their apparently reflex cause, but I have several cases which seemed to point in that direction. These disorders, of course, produce reflex disturbance; this reflex disturbance produces a change of metabolism of some sort. Before we can get at these incipient causes of the disorder we must know more physiology; we must know what these reflex disorders produce in the way of change, metabolic disturbance. We must know what are either the produced poisons or the interferences with excretion which put the system in a state of disordered metabolism and bring about these mental changes; and until we make progress in that direction I think there is very little to be expected from the investigations upon the chronic states, which, as Dr. Meyer has well pointed out, may take a variety of courses, depending very largely upon the individual characteristics, upon the peculiarity of physical organisms.

I wish to say one word in favor of what has been suggested by Dr. Puntun in regard to a detention hospital. It has been for years in my mind a necessity. It has been our experience, in Michigan at any rate, that we have in connection with our insane hospital staff men who have very little experience in general practice; men who have grown up, as it were, in asylum work; men who have not had an opportunity, for instance, to deal with questions of ophthalmology, of gynecology, of general surgery. Their range of experience has not been sufficiently wide to thoroughly canvass a case of this sort in its incipient stages. It seems to me a detention hospital, where these cases could be taken and dealt with in every aspect of the case, would be very helpful and would result in a great many more of them being saved from chronic melancholia or insanity.

Dr. TOMLINSON of Missouri—I would like first to enter a protest against calling every depressed individual a case of melancholia. My understanding of melancholia is that it is an entity, the principal characteristic of which is that there is no mental reduction; in other words, that the intellectual capacity of the individual is retained, and that if that is not present it is not a case of melancholia. A man may be depressed because he is demented, but it seems to me absurd to call everyone who is depressed a case of melancholia. I am very sorry to see what I might call the syllogistic methods of our clinical friends enter into the discussion of the treatment of insanity; that is, that so-and-so found such and such a state, and that a given result was produced; ergo, that the result was caused by that condition. I do not think it is scientific, and I do not think it proves anything. I think a detention hospital is all right, but it is still a hospital for the insane, and if it were once established, to make it competent to perform its work it would have to have all the surroundings, all the accessories and all the facilities which characterized a hospital for the insane, and then what would it be but a hospital for the insane? If it were a State institution everyone would insist that their insane should be sent to that detention hospital and be kept there as long as possible.

Dr. WOODSON—I think that all alienists are agreed that, taking into consideration the cases of melancholia that come under their treatment, that form of insanity greatly exceeds all others. Again, I think that all alienists will agree that a very large percentage of the ordinary cases of melancholia end in recovery, and there is nothing more beneficial than the improvement of the patient's general health. When you get your cases of melancholia to partake freely of milk and medicine, and take exercise in the open air and sunshine, especially so if they are inclined to take on flesh, they almost invariably recover. In giving advice to the friends of the patient when he is being taken from the institution, the invariable advice is, "Do not permit the patient to run down or decline in health." So far as detention hospitals are concerned, I have this to say: If it is reasonable to presume that a detention hospital will be better equipped or provided with better physicians or men more experienced in gynecology, insanity, general medicine; then there is no reason why it should not be nearly as good as the general institution. But is it not possible to treat melancholia in a general hospital. In regard to the discussion yesterday, some gentleman said that no gynecologists are in favor of performing an operation to restore the insane mind, unless there is a pathologic condition demanding the operation. So far so good. I say if there is a woman who has a pathologic condition which demands an operation, or would demand it in health, it should be performed for the purpose of restoring that part if possible, and if perchance it does further and better the condition of the mind, so much the better. No neurologist is justified in saying to a gynecologist that by removing the appendages of the uterine organs it will cure the mind, because

he does not know that it will. In an experience of eight or ten years I can report twice as many cases of insanity that are attributed to operations from the hands of our distinguished brothers—more cases than they reported as having been restored! They said nothing about the number of cases that had become insane from the operations, but they herald to us the cases that they have restored.

Dr. SEARCY of Alabama—Possibly as good a definition as we can make of that condition of consciousness which we call "melancholia" may be that it is a general sense of disability or inability on the part of the person in his capacity to adjust himself according to what he wishes to do. But there is in melancholia, more or less, an ability to reason. It is not a demented state. There is an ability on the part of the patient to think, and his melancholic condition is one of a sense of disability. What brings that about is largely a natural tendency in the person to take that way to think; it is a hereditary tendency to depression of spirit and of feeling. A large part of our neurology is cerebrology; a large part of neurasthenia is cerebraesthesia; and a great part of the work of neurologists is that which relates to the conscious organ, the brain. The other day I was in the Medical Section when the subject of consumption came up, and yesterday every one was willing to talk about headaches, and today when we speak about melancholia, we find that every one is ready to talk about melancholia, because all those subjects are frequent fields of thought. In those conditions of the system that produce cerebropathic states possibly nothing tends so much to bring about melancholic states as toxic conditions that arise from the alimentary canal. The melancholic patients, as soon as you can get an aseptic state of his digestive apparatus, will generally improve, and as soon as you can put his system in such a state that he is relieved of toxins, whether they come from the pelvic organs or anywhere else, this will tend to relieve his melancholia. In general practice the largest part of our medication is in the direction of rendering the digestive tubes aseptic.

Dr. CHARLES H. HUGHES—The chair would like to express his extreme surprise that Dr. Puntun should make the statement that the environment of an insane asylum is against the recovery of ordinary acute melancholia. This, in my judgment and observation, is not true. The best influence that you can bring to bear upon an insane man is a change of environment, and if the insane man is in such a condition as to receive any sort of impression from his environments an insane asylum is the best of all kinds, with its illustrations, its object lessons of insanity, its object lessons of melancholia in other persons, its methods of diversion and means of rest, and its removal from home. All this affords the best opportunity for the cure of melancholia. I have seen far more melancholics recover in insane asylums than ever recovered out of them; I have seen a larger percentage of melancholia recover inside of an asylum than of any other form of mental aberration, except acute mania, and I think great injustice is done to the value of insane asylums by a statement of that character. These attacks that are made upon medical men when they get into an asylum are strangely inconsistent to me. A medical man is just as good a medical man after he goes into a lunatic asylum, unless he goes there as a patient, as he was before. He generally has a wider field of observation, and some of the most discerning diagnosticians I have ever encountered were those who had learned to diagnose the insane, who hindered and retarded, instead of helping your diagnoses. The cure of melancholia consists of diversion, of recuperation, and also of rest. It is the changed environment that effects the average cure of the melancholic. As has been stated, if you can save a melancholic from killing himself you can almost always cure him.

Dr. NORBURY—I admit that melancholy is a symptom just as fever is. I believe, however, taking it on the whole, we have a recognized disease of melancholia, without going through the progressive dejection of which the text books speak and which Dr. Tomlinson mentioned. You may have a case of profound melancholia following uric acid poisoning, with classic symptoms. The gentleman from New York State speaks of his so-called failure with the Haig cases. I would say that these cases are cases of short duration, and do not get into insane hospitals. I have in mind two cases which I have seen in the past three months; one case went home just before I came to Colorado, one in a general hospital—not in the insane hospital—following the uric acid condition. By cleaning up the uric acid, you relieved the melancholia and even the delusions, which, in this case, were not profound. The man was not in the hospital more than three weeks; I do not say that he had recovered, but the mental symptoms had cleared up. Another case of renal calculi presented the ordinary classic symptoms of renal calculi, suppressed urine,

intense pain, etc. There was a period of dejection with marked suicidal delusions. With the discharge of the calculi the patient has improved. What we need in the consideration of melancholia is more attention to the internal medicine aspect of the case; we need more attention to the diagnosis, more attention to the study of the case from the basis of internal medicine.

HOW TO LIMIT THE OVER-PRODUCTION OF DEFECTIVES AND CRIMINALS.

Presented to the Section on State Medicine, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY J. H. McCASSY, M.A., M.D.

FORMER SUPT. OF KANSAS STATE INSANE ASYLUM AT TOPEKA.
DAYTON, OHIO.

Upon the solution of this problem hangs the fate of home, nation, and civilization. It is the concern of all good citizens to do something to improve posterity. During the past ten years the population of the United States has increased 25 per cent., but during the same period crime increased 60 per cent. The cost to the public for the care of defectives and for the prosecution and support of criminals is enormous, to say nothing about the destruction of life and property, confidence and morality. We go on building asylums, hospitals, reformatories and prisons, and we keep them full. Imbecility, idiocy, insanity, epilepsy, deafness, blindness, incorrigibility, youthful waywardness, adolescent vice, immorality, and adult criminality multiply apace in the land. It is high time to improve the method of preventing over-production of defectives and criminals. We are too prone to assail results or salve over the surface of our social sore, leaving the roots untouched. No one can afford to ignore this subject. It concerns every taxpayer, and every one who makes his own living is a taxpayer, whether he owns real estate or not. The problem consists of prevention, reformation and extinction. The basic causes of crime must be attacked.

The ancient uncivilized nations knocked their old men and old women in the head; strangled the superfluous babes between thumb and finger or left them to perish upon the mountain side; and threw their defectives into the water or fed them on the juice of the poppy as a less brutal means of effecting their exit from this world. Criminals among inferior peoples are comparatively fewer and are not dealt with tenderly. A dose of tomahawk ends their career. They are little or no tax upon the public, and they are very little in evidence. The lower stratum of development in savagery and barbarism produces comparatively fewer defectives than do the enlightened and educated strata. While the highest types of individual and national growth, power, education and excellence are attained in our modern social development, nevertheless, the wayside is strewn with failures; although defectives and criminals are largely bred from the same classes, a great many recruits come from families of high standing. It is not necessary to scan very far along even good family lines until you come to a stray sheep, and often a black one at that. A defective and a genius may be found in the same family.

The Roman and the Greek laws did not bother much with moral improvement. The best test of modern civilization is shown by the way the defectives are treated. Society admits that the criminal has some rights which it is bound to respect; and not the least

of these is the right to reform. The defectives must be cared for in the most humane and conservative manner. Barbarism and brutality are not economical for up-to-date nations.

PSYCHOLOGY OF CRIME.

Although criminal offenses appear to be spontaneous and impulsive, yet if they could be traced they would be found to be due to a variety of causes. Modern science teaches that nothing *happens*. Everything that comes to us is pushed from behind: In society, as organized at present, there are constantly at work forces which germinate crime and disorder. Seven thousand murders take place annually in the United States. Ninety per cent. of the reading matter upon which the community feeds tends to disintegrate character and bring disorder and abnormality into prominence. Our daily and weekly papers are devoted largely to illustrating crime and immorality. The sediment left after the reading of murders, suicides, thefts, and immoralities, poisons the youthful minds and leaves indelible scars upon their tender souls. All pictures thrown upon the mental canvas modify their recipient accordingly as they are good or evil. Persons are swayed by the character of the pictures before which they linger. The scientific way to destroy evil is not to hold up and analyze it in order to make it hateful, but rather to let it pass out of consciousness. If we hope for improvement in the generation unborn we must dull the appetite for "blood-and-thunder" fiction. It is useless to ask the publishers to abandon a paying business. By a crusade of education against vice, we must lift the minds of our generation above the present demand for sensational reading matter.

All education, physical, mental or moral, is primarily a cultivation of powers of resistance. Cares, anxieties, business and social difficulties prey upon the mind; and if they are not repelled insanity is the result. Depraved natural appetites, if unrestricted, result in crime. We guard against physical disease by building up the tissues and selecting healthful environment. We guard against mental disease by educating the mind and avoiding pursuits that bring excessive intellectual strain and dissipation. We may guard against crime by educating the higher ethical sense and by removing the temptations to wrong-doing. Certain mental equipments are suitable for certain occupations. When a person selects proper pursuits in life success and happiness will likely follow, but a wrong selection brings misery and crime. There came to my notice a case which illustrates one phase of this subject. Two brothers, many of whose relatives had gone insane, started to study medicine. The strain on both to keep up with the class was great. When they were nearing the end of the second term, one of them went hopelessly insane. The other studied the literature of his case, and when he found inherited insanity in his family history he concluded to abandon further study of medicine. He went to farming and made a great success in raising cattle and hogs. He said that the nearer he got to the simple ways of living the better he felt. He became a good and prosperous farmer.

The criminal differs from the normal being in the fact that he has less power of resisting crime. We all have the criminal tendency more or less, but it is suppressed by cultivating higher instincts. If the child of the criminal is allowed to grow up under the

tutorage of crime he will be a criminal. If the same child is brought up in a good family, the results will be better. It will not, however, do to depend too much on environment. Favorable environment will overcome inbred propensities to a certain extent, but in many cases, where there is too much to overcome the over-mastering criminal propensities will land the unfortunate victim outside of the pale of good organized society. In this fact lies the great responsibility of childless families in procuring recruits from the Orphans' Home. Years of unremitting toil and loving care may be reduced to naught by the explosion of their inheritance of vice. Take, for example, Bessie Little of Dayton, Ohio, who was taken from the Orphans' Home and reared in a good family. She got along very well until she reached full maturity. Then her born erratic tendencies and insatiable egotism took possession of her. She loved Franz, her slayer, in his presence and hated him in his absence, because her judgment was dethroned by her passions. In this case the best of environment was inadequate to overcome her inheritance of vice; she broke down and became a criminal.

Heredity is nearly everything. "Blood will tell," and blood does tell. A born idiot can never be more than an idiot, but these form only a very small percentage of the defectives. Of all the streams of evil that flow into the national blood none is more virulent than that of imbecility. It is the legitimate offspring of the jail, the infirmary and the insane asylum. What a remarkable lesson there is in the case of Max Jukes of New York State. He was a Dutch settler, born about 1740, a hunter and fisherman. He was a great drunkard, and the progenitor of 1200 persons, nearly all criminals, vagabonds, paupers and prostitutes. In seventy-five years the descendants of Jukes committed 115 criminal offenses. Not more than 20 of them were skilled workmen, and ten of these learned a trade in prison. This family cost the State of New York one million dollars. Crime, imbecility and insanity are due in 60 to 75 per cent. of cases to heredity. We do not expect to entirely eliminate bad blood from the race, but that we can greatly lessen it is both possible and probable.

Insanity is much more prevalent among the Quakers or Friends than any other religious sect, perhaps, because of their sadness and gloom in religious worship. Insanity is less prevalent among the colored people than any other race, because of their simple wants and happy disposition. The general causes of insanity are: heredity, 50 to 60 per cent.; whisky, 12 per cent.; religious perversion, 10 per cent.; disappointment in love, 10 per cent. Eighty per cent. of drunkenness is due to heredity; alcohol causes 33 per cent. of the diseases, 75 per cent. of the crimes, and 50 per cent. of the poverty that afflicts our race. Intemperance of parents causes 34 per cent. of the imbecility in children. Drunkenness in the parent may not be followed by drunkenness in the offspring, but epilepsy or kleptomania, hysteria or apoplexy in the mother may be followed by some form of insanity in the offspring. Parents transmit not alone their inherited tendencies, but their acquired peculiarities as well. There are 100,000 orphans in the United States. One-fourth of these are classed as juvenile delinquents or defectives. It costs ten million dollars a year to care for those orphans. Dr. John S. Billings, in charge of the Census Office, gave us the following figures for the whole United States in 1890:

Insane, 106,254; imbeciles and idiots, 95,571; blind, 50,411; deafmutes 41,283; paupers, 73,045; prisoners, 86,000.

SEX IN RELATION TO CRIME.

Females, being physically weaker than males, are addicted to crime only one-fifth as frequently, and only excel the males in the commission of poisoning and infanticide. Woman's natural form of retrogression is prostitution.

SEASON IN RELATION TO CRIME.

Crimes against property are more prevalent during the cold season of the year and in cold climates, while crimes of passion and against the person are more prevalent in warm climates and during the hot season of the year. Intemperance is prevalent in the temperate zone. The boy asked his father how it happened that people drank so much beer and whisky in the temperate zone.

CAUSE OF CRIMINALITY AND DEFECTIVENESS.

Population has increased too rapidly. More children have been born to poor people than they could rear properly. To raise and educate properly one child requires enormous outlay. To raise properly one child would be a big task for most husbands and wives, to say nothing about six or ten children. Parents of education and means rarely have more than two children. If they have a third child, it is a mistake. This is the cause of a lack of growth of the population at the top and of an excessive growth of the population at the bottom. According to vital statistics it takes on an average about $3\frac{1}{2}$ children to each couple to propagate their kind. Too many people are heedless of all Biblical commands except "multiply and replenish the earth." The next great basic cause of crime and defectiveness is the implied inferiority of women. The idea of woman's inferiority has come down to us from a barbarous past. The man-made laws have, all along the line, accorded the male sex dominion over the female, which has placed millions of girls and women at a disadvantage in the struggle for bread, and which compels thousands of them yearly to accept degradation or starvation. This has kept the moral fabric of society weak. Improvement in our race is an idle dream until woman is accorded perfect justice and placed squarely on equality with man. The helpless slavery of woman, with the attendant evils of enforced motherhood must be relegated to the rear as a crumbling relic of barbaric injustice. If the father be the head and the hands of the family, *the mother is the heart*.

A child has a right to be well born. The man whose destiny is unfavorably formed for him by his ancestors is to be pitied. Many of the rich and poor are alike born into this world with an inheritance of vice and degradation. They are crippled from the very beginning, and have only half a chance for health and prosperity. The end and aim of sex and sex-relation is simply the perpetuation of the species. Sex relation has been diverted from its proper mission. As an example, 40,000 abandoned women are to be found in the city of New York. The *Arena* for January, 1898, gives the following figures for Massachusetts, New York and Illinois: Sixteen per cent. of the married men desert their wives after the birth of the first child, and 28 per cent. after the birth of the second child. The children of such parents are placed at an immense disadvantage. Add to this the work of the wholesale divorce mill and it will be apparent that

marriage to a considerable extent is a failure. Women have opened their eyes to this condition, and as a result 18 per cent. of women of marriageable age in the United States have equipped themselves for earning a living independent of man. She is a worthy competitor of man today in manufacturing, mercantile, professional and other pursuits. When women can completely assert their independence there will be improvement in motherhood. Improved motherhood is the safeguard of the generation unborn.

Our civilization has developed so rapidly that it has retained many of the elements of barbarism and savagery. A relic of savagery is inculcated in this: "He who would not avenge an insult is no man." "Manly dignity can be preserved by executing justice himself, not waiting for the medium of the law." In this way violence comes to be regarded as a virtue, revenge as a duty, and crime as heroic. In this there is a tendency to return to barbarism which blunts the moral sense. The second phase of modern civilization is characterized, not by violence and crimes of blood, but by craft and deceit, as adulterations in commerce, tricks of exchange and official fraud. There is a choice of becoming either hammer or anvil; the person who can not crush another without feeling pain must remain an anvil. Still the weak must serve the strong. The world bows to him who possesses more than others. This is the state of society, notwithstanding the bombastic and hypocritical assurance of brotherly love. Never before in the world's history has a person needed keener wit, greater frugality and prudence to make a living than now. The struggle is fierce and many are falling by the wayside.

Heredity is the great causal factor of crime. Next to this comes intemperance, which depends largely upon the former. It is not encouraging to note that the legal or legislative handling of intemperance has been a failure either in prevention, restriction or cure. The drink habit is still spreading. The greater portion of crime arises out of our social conditions and is amenable to reformatory measures. Only about 20 to 25 per cent. of criminals are born criminals. Three-fourths of the crime in our land is caused by neglected education.

Another source of the multiplication of crime in this country is the almost unrestricted immigration of the lower classes of foreigners from all lands. Our population has 20 per cent. of foreigners in it but they furnish more than half the inmates of our reformatories, one-third of our convicts and three-fifths of the paupers supported in almshouses (F. H. Wines. D.D.; Report in 111th Census).

Another cause of crime and pauperism is the undue flocking of the urban population to the cities. Our jails and prisons are simply high schools of depravity and nurseries of criminals. In the jails our courts husle ravishers, corrupters of youth, murderers, burglars, thieves, drunkards and all the foul members of society, with children convicted of petty larcenies or of incorrigibility, with detained witnesses and people accused of misdemeanors or crimes not yet tried. The inmates of the jail are liberally supplied with tobacco and cards. The junior offenders soon become assimilated to their hardened companions, and join the ranks of crime. The very air about the jail or prison reeks with crime. The criminal serves out his sentence in comparatively comfortable quarters, or he is pardoned out and turned loose upon a long-suffering public, upon which he preys and commits atrocities

with increased skill. It is said that only about one-tenth of the criminal offenses are detected and punished.

In our advanced state of civilization, excessive culture has introduced new forms of crime, such as homicide for life insurance and the abuse of alcohol, cocaine, opium and other narcotics. The negro was transplanted on American soil against his will by the whites and kept in slavery 260 years. The negro forms 12 per cent. of the population of the United States; commits 33 per cent. of the crimes; contributes 8 per cent. of the paupers and only 5 per cent of the lunatics.

To sum up the cause of the over-production of defectives and criminals, it can be stated in one sentence, viz.: Disobedience to the laws of nature and of physical hygiene during the present or preceding generation. From the cradle to the grave man is in constant danger from the effects of violated laws.

HOW TO REMEDY THE OVER-PRODUCTION OF CRIMINALS AND DEFECTIVES.

This will involve a removal of the causes just enumerated. Society concerns itself too much with the punishment of crime and not enough with the prevention of it. The lessening of crime is as much a subject for education as for legislation. There is little use in passing laws in advance of public sentiment. Only one person in ten who has an opportunity to steal is restrained by thought of law. His conscience declares that it is wrong and that is enough. Good healthy sentiment needs to be awakened with a view to the suppression of crime. Wholesome laws will follow in the wake of public sentiment. A law without the moral support of the community is useless. If society stamps out crime it will not be the work of one generation, or of any single specific. A great many remedies must be tried. Punishment holds crime in check only, but does not put an end to it. Crime is more formidable than pauperism and is almost as costly. Only a small percentage of the evils afflicting society spring from want. A small number of crimes are due to sheer want of food. But prosperity generates criminal inclinations as well as does adversity, and on the whole the rich are about as much addicted to crime as the poor. Increase of material prosperity may reduce crime against property, but it increases drunkenness and crimes against the person. Increase of wealth must be accompanied by a healthy growth of morals to be a benefit to society. Our educational institutions could accomplish more, if more prominence was given to instruction in conduct and morality, but it is more essential that these should be taught and practiced in the homes; and to this end improvement of motherhood is indispensable. In the proper training of young children lies the best means of the prevention of defectives and criminals. A child at the age of five or six years has imbibed many ideas that cling to him during life. I lay great stress upon the training of the rising generation, because more can be accomplished by preventing the formation of bad habits in the young than by trying to reform confirmed transgressors.

PRISON REFORM.

The treatment of the criminal should fit him rather than the crime. The nature of the criminal should be studied, and suitable chastisement meted out to him. It should be corrective rather than punitive.

A course of instruction in conduct and the duties of citizenship should be part of the prison work. The youthful offender should be dealt with kindly. The efficacy of fines should be well tried before resorting to imprisonment. Junior offenders should not be classed with old offenders. Offenders for the second and third time should be classed as life convicts, and be compelled to "work out their own salvation." There should be rewards for toil and punishment for idleness. Labor organizations are on record that convicts should work, but for thirty years they have protested against convict labor coming into competition with free labor. Convicts should work, but how to employ them judiciously without having their labor come into competition with free labor is difficult to solve. The product of their labor should go in the direction of manufacturing articles for the charitable and penal institutions. No one should object to this. Capital punishment is a crumbling relic of barbarism. The murderer is not put to death as frequently as formerly. In another generation the death penalty will be abolished. Two wrongs do not make a right. It is folly to slander the slanderer or to steal from the thief. The death penalty used to be inflicted in public, but it was found that publicity of crime was detrimental to the suppression of crime. Many people commit crime from imitation by seeing it illustrated in the newspapers. The term sentence for prisoners should be abolished. The curable should be cured and the incurable should be kept for life in seclusion, at self-sustaining labor. It would be ridiculous to sentence a lunatic to an asylum for one or two years. The criminal should be given an immediate sentence and his liberty should be abridged until he proves himself worthy of the confidence of the community. The board of pardons should be made up of the sentencing judges, the warden of the prison and one of the chief justices of the State. This board should meet quarterly, hear evidence and correct mistakes of sentence.

According to sanitary laws, your house may be quarantined and the family prohibited from mingling with the public. According to the school laws your children are taken from you five hours per day, from the age 8 to 14 years, for educational purposes. In view of all this, it seems reasonable that laws could be enforced to keep poison out of the blood of the nation. The State should abridge the liberty of criminals and defectives earlier in their career of destruction. The truest kindness to the defective is to prevent him from being born, because he is his own greatest curse. Often the greatest liberty is the greatest curse and danger. The issuing of marriage license should be restricted by requiring medical and other affidavits to be filed with the probate court showing that the applicants for marriage license are free from insanity, criminality and other hereditary taints. The great majority of defectives and criminals can earn their own living under efficient supervision. There should be more institutions in the land like the Elmira Reformatory, and colonies for the care and keeping of defectives. The outlay now would prove a great saving in the future. Prevention is better than cure. It is better to keep the murderer from coming into existence than to smooth his pathway to the gallows. It cost the State about \$20,000 to try Durant; \$20,000 to try Jackson and Walling; \$25,000 to try Luetger. The cost to the State for trying an alleged murderer, if put on interest, would keep a person a whole lifetime in comparative luxury.

ASEXUALIZATION.

I have given this subject much thought. I have felt the pulse of the public for a long time in the radical and conservative arteries. I think the treatment would be effectual, but the difficulties lying in the way are at present insurmountable, except for friendless paupers. It would be impossible to follow it out through all the ramifications of heredity when genius and insanity, brilliancy and imbecility are found in the same family. Society, as organized at present, accepts the proposition of reforming the whole man, not part of a man. Amputation of a thief's both legs would incapacitate him from being a successful robber, but society will not accept such treatment. Asexualization of adults often leaves a troublesome amount of sexual desire, and even if it is done in childhood, there is by no means a total absence of it, though it is much lessened. Oriental people, including the Turks, have tried this treatment among the Eastern eunuch and have no confidence in it as an agency for moral reform. The eunuchs were shameless, melancholic and often suicidal, as well as defective in courage, gentleness and remorse. Although the valleys are deep and dark, we must not dwell in an atmosphere of gloom, but must move on and up toward the greater light, realizing that with every step taken vision becomes clearer and more comprehensive, and that positions occupied today with safety were yesterday inaccessible. The hill-tops of science are luminous, and the public sentiment of the future is destined to be more and more informed by science and will eventually adopt its suggestions in matters of statecraft and social economics.

Rape is frequently caused by diseased sexual passions. Surgeons daily remove tumors and limbs for the cure of disease. To asexualize the rapist would protect against repetition of the offense. The punishment would be none too severe. The rapist should take the radical treatment. How many rapists under sentence for five to twenty years would accept this operation as the price of freedom, would be difficult to say. If this class of criminals were given one year after sentence had been pronounced in which to accept this operation as the price of their liberty, only a small percentage of them would remain in prison.

Asexualization of defectives and criminals, both male and female, would speedily limit the dissemination of disease, vice and crime. It would remove their obliquities and transform many of them into useful and productive citizens. By eliminating their productive capacity it would diminish their numbers and permit a rise in the physical, intellectual and moral standard of the race. Owing to the innate repugnance toward this condition, as a penalty for crime, it would be a powerful deterrent and thereby diminish crime, protect against many ravagers, and satisfy the vengeance of the outraged community. Ignorance, intemperance, poverty, disease and defects are symptoms indicating a social state or condition of crime and pauperism rather than the cause of them. Society maintains alive those that would perish without its aid. It is folly to permit the breeding of social gangrene.

The reproductive organs have no function in the human organism except the creation and gratification of desire and the reproduction of the species. Their loss has no effect upon the health and longevity of

man. Their removal would destroy desire and diminish the wants of nature. A want removed is equivalent to a want supplied. It would be a kindness rather than an injury to abnormal persons. The operation is simple, safe and painless. It would confer upon inmates of prisons, reformatories, etc., immunity from evil practices, and give them health and strength, satisfaction and comfort for discontent and insatiable desire. The prevention of reproduction should not be objectionable to this class, because idiotic, insane or criminal children are of no comfort to parents. Such surgery is as wise and merciful as vaccination or the extraction of a decayed and aching tooth.

In the *Cincinnati Lancet-Clinic*, Oct. 3, 1896, will be found a description of an operation invented by the writer for the cure of certain cases of insanity. The operation consists in cutting or exsecting from one-fourth to one-half inch of certain branches of the pudic nerve. This causes a suspension of the sexual activities for a period of from one to four years, with a return of same as soon as the nerves are reunited. This operation has not been in use long enough to judge of its usefulness. The sexual instinct was implanted for the propagation of the race, not for its degeneration and destruction. Humanity sins against the Creator by contributory neglect in this matter. Society arrests and confines the lepers, the victims of smallpox, yellow fever or cholera, and treats them as it sees fit. It shuts up the imbecile, the criminal and the insane for the protection of the public. No one questions its right to do so. Yet it allows the deformed and diseased in mind and body and soul to disseminate social leprosy and cancer. This could be prevented by the adoption of an operation almost as simple and painless as vaccination. It seems strange that the matter should be delayed so long. Asylums, prisons, and jails can not be built fast enough to meet the requirements of social neglect. Society is working at the wrong end of the subject. It should get at the rottenness of the root of the tree of humanity. The upper tenth in society has remained about the same for 3000 years. There used to be no submerged tenth, but today we have a largely increasing submerged tenth. There is a lack of growth at the top. Stature and health are decreasing. Weak nerves and weak stomachs are on the increase, as the result of faulty breeding. The decay of the Republic is due to the degeneracy of the people. It is an outrage that the State and Nation stand idly by and permit the intermarriage of criminals, paupers and defectives, thus becoming a party to the wholesale manufacture of probable criminals. The State has the right and power to prevent the probable from becoming the positive criminal.

History records that many cities have been built on this earth, some of them nearly as large and as rich as any of the present age, yet through internal disease they went down in ruin, and nothing but potsherds and broken brick remain to mark their former existence. It is time to put up the signboard and suggest whither we are drifting.

Let the nation adopt the plan of treatment herein suggested for one generation, and the result would be that all the inherited rottenness and corruption of ages would be purged out of the people. The criminal and pauper class would become extinct. Asylums, prisons and jails would become depopulated. The great burden of taxation would be lifted from the people. Doctor's bills would be less of a drain

upon the family and chronic disease would be diminished. Let the sword of justice cut the knot of bondage and let society take control of its own destiny and regulate reproduction with the wisdom of experience, and the "ills which flesh is heir to" will vanish before the glorious dawn of the day of comfort, hope, peace and promise.

A CASE OF ACROMEGALY.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY HENRY WALDO COE, M.D.

Physician-in-Charge, Mindsease Sanitarium; Consulting Neurologist to the Oregon State Institutions for the Deaf, Dumb and Blind, etc.

PORTLAND, OREGON.

Although acromegaly was first described as a medical entity in 1886, since that time (Woods Hutchinson) two hundred and fifty cases have been reported, of an average of about twenty per year. When it is taken into account that probably at least one-half of these reported cases, like the one herewith submitted, were recognized, although not classified, before Marie brought the subject into prominence, it may not be deemed unreasonable to say that, the world over, ten represents the number of cases annually developing into the malady of acromegaly, and that it is, therefore, one of the rarest diseases known. The subject of acromegaly has been scientifically presented by numerous investigators quite recently, a list of several of the latest of these papers being found at the close of this report, and for the purpose of increasing the number of reported cases and to enhance the value of the more scientific papers on the subject, the following is briefly given:

Case 1.—Mrs. F. B., German extraction, aged 68, married, occupation, farm wife. Father living, in good health, aged 93. Mother, who had always been in good health, died recently at the age of 91. Several brothers and sisters are living, and all are, as far as can be determined, in good health, but each of these has a highly developed nervous system. All the members of the family are above the average in size, but no giantism or acromegaly is elsewhere reported. A negative history presented of tuberculosis, heart or other organic disease elsewhere in the family, while there is no special history of former serious illness in the patient herself.

Nothing abnormal was discovered in her physical condition until 50 years of age, when the irritability of the nervous system, characteristic of the family, began to be more pronounced, and defect in the exercise of normal will-power more manifest. The normal processes of cerebration declined rapidly, and on Feb. 21, 1893, she became so homicidal that she was committed to the Oregon Insane Asylum at Salem, where she has since remained. To Dr. D. A. Pain, the superintendent of that institution, I am largely indebted for much of the data making up this report. At the time of examination for commitment the physician making the same reported as follows: "This patient is a large, fleshy woman, with the vegetative functions well performed. Her lungs and heart are normal, as are all the organs so far as can be determined. Mentally, all the perceptions are normal. Her emotions are moved to great rage without provocation, or to great affection, although the latter much more rarely. Her intelligence is limited and she is incoherent in speech. Her will controls her only in mani-

feeding her physical wants. She is abusive in her language, and sometimes violent with her hands."

No record was made at the asylum at that time of any special deformity of any portion of her body, and as the report of the examining physician of the committing court seems to show that a careful examination was made by him, and as he says that she was physically in a normal condition, we may therefore reasonably presume that acromegalous enlargement and deformity were not at the time present, or if so, in so slight a degree as to be unnoticeable. The incoherence, however, may have been a lingual ataxia from an enlargement of the tongue, already beginning at that time.

Three years later, the hospital reports spoke of the tongue as "large," and also that the "feet and hands are larger than usual." At this time such report also says, "bowels regular." Good pulse. At irregular intervals her face and neck became congested. Coarse, loud, vicious, and profane in speech, which is in a coarse, low-pitched voice. Delusions and hallucinations. Her general condition remained much the same, her mental state showing increased impairment, and on June 6, 1889, we find that she was reported as well-nourished, with bodily functions fairly well performed, and that she had constant delusions, illusions and hallucinations, although she did

not always obtrude them. Occasionally she was noisy, excited, abusive and violent, and her reasoning power and memory were defective.

Five years later, June, 1894, her physical condition was good, all functions being well performed. "Face, hands, feet and body generally enlarged. The tongue being too large to remain ordinarily within the mouth, is always protruded when she sleeps. Excitable and violent. Locomotion somewhat impaired, and no particular desire to move." At the present time she is able to walk only with much difficulty, from general weakness and ataxia. She prefers to, and does, sit in a large arm rocking chair most of the time. She has delusions, one of which has been fixed for many years, that is, that her former "neat, tidy and small body was stolen, and they put me in this big, ugly body." She is well-nourished, eating and sleeping well. Her extremities have shown further growth, and her hair has notably grown coarse during recent time. Most of the joints are normal, although all the metacarpophalangeal articular extremities are enlarged. Soft parts of the fingers enlarged, of sausage-character. The inferior maxilla has grown prominently forward, and the teeth in closing extend beyond the upper three-fourths of an inch. Zygomatic

arches somewhat prominent, and the nose and ears larger than normal. The superciliary arches protrude slightly. The spine is normal. The thyroid is small, the thymus not discernible. The sternum is increased in size, and the whole chest enlarged. The clavicles are thickened. She is strong and vigorous in general appearance, and weighs 202 pounds. Her present height is 5 feet 5½ inches. Length of arm: axillary fold to tip of finger, 24½ inches. Length of middle finger, 3½ inches. The thumbs seem shorter than they should be, relative to the fingers. Finger nails coarse and thick. The circumference of the head is 22 inches.

There is no sugar in the urine, and Dr. J. T. Williamson says that there is no record of any diabetic symptoms having been present since his connection with the case, eleven years ago. Her pulse is usually rapid and her respiration slow. She has a blowing murmur with the second sound of the heart.

A feature of possible etiologic interest in this case is that the father and mother were first cousins.

THE ARTIFICIAL FEEDING OF INFANTS IN GASTRO-INTESTINAL DISTURBANCES.

Presented to the Section on Diseases of Children, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY J. M. G. CARTER, M.D., Sc.D., Ph.D.

Professor of Clinical and Preventive Medicine in the College of Physicians and Surgeons, Chicago (School of Medicine, University of Illinois); Fellow of the American Academy of Medicine; Late President of the Illinois State Medical Society, etc.

WAUKEGAN, ILL.

Careful study of artificial feeding must be made in two classes of patients; 1, infants whose mother's milk does not agree; and 2, whose mothers are unable to nurse them. Some of these cases may be supplied by a wet nurse and perhaps everything pass along satisfactorily; but so much trouble is sometimes experienced with wet nurses and so much success attends artificial feeding by means of cow's milk, that many physicians today have almost entirely abandoned the wet-nurse method of feeding babies, especially in view of the fact that it is often difficult to secure a wet nurse whose constitutional history is entirely satisfactory.

In every case it is necessary to determine the cause of disturbance. Not until this is done is the physician in a position to permit or advise the adoption of an artificial diet. The most common cause of digestive derangements in infants is some fault in the feeding. There are at least four factors in this cause, one or more of which are usually present: 1, the food may be poor in quality; 2, it may be deficient or too abundant in quantity; 3, the interval between feedings may be too short or too long; 4, the food may not be of proper temperature. Rarely, cases of congenital malformation or imperfect development of the secretory apparatus of the stomach may cause trouble, even

when every precaution has been taken in regard to quality and quantity of food, and where proper intervals between feedings are scrupulously observed.

The first inquiry has reference to the source of the food. If it is mother's milk the health and temperament as well as the disposition of the mother must be taken into consideration. If the milk is too acid the administration of a little lime-water after each nursing may correct the difficulty. The mother's milk may contain too great a relative proportion of proteids and because of this constantly give rise to digestive derangements. In such a case, as well as in some others, the use of mother's milk is often necessarily abandoned and some form of artificial food prescribed. If the disturbance has continued until organic lesion of the stomach has supervened, as chronic dyspepsia or gastritis, additional modifications of the food may be required. Partial or complete predigestion or peptonization of cow's milk, especially for older children, may do very well in a few cases. In many cases, however, it is a long and tedious task to find a preparation which will entirely remove the condition and relieve the symptoms.

Next to mother's milk cow's milk is the proper food for infants; but it must be modified in the relative proportion of its elements so as to correspond with human milk. Each case requires special investigation. If there is constipation and a poorly nourished condition of the patient, cream should be given in larger proportion than in cases of well-nourished infants with a tendency to diarrhea. Bearing in mind the fact that normal human milk is alkaline, while cow's milk is neutral or acid, a necessity will be recognized for using a little lime-water with cow's milk. If the milk is not sterile it ought to be sterilized. If proper precautions have been taken in milking the cow, and the milk is passed *at once* into sterilized bottles, a healthy cow's milk is *sterile* and needs no heating except to raise it to proper temperature for feeding the baby—about 98 or 100 F.

It is necessary to analyze the milk before a proper comparison with human milk can be made; but when the exact composition is known, a simple calculation enables one to make the proper modifications. The method of procedure may be illustrated by referring to a case in my practice recently: The baby had considerable digestive disturbance and two or three slight convulsive seizures. The mother was tired and nervous, and anxious, but she had previously nursed two children without any disturbance whatever. This latter fact made it hard to convince her that the food was the cause of the disturbance. An analysis of her milk showed that it contained 2.80 per cent. of proteids, a proportion entirely too large. Otherwise the mother's milk was normal. The simple problem was to prepare a food from cow's milk which should equal human milk. The milk of the cow which belonged to the family was analyzed and found to consist of water 87.3; fat 4; lactose 5.69; proteids 2.80 per cent. Normal human milk contains water 88.4; fat 4; lactose 6.50; proteids 1.80 per cent. To reduce the cow's milk which we were to use in this case to the equivalent of normal human milk the following changes to make 500 c.c. for baby were used: Milk 312 c.c.; water 178 c.c. (water 174, lime-water 4); cream, 9 c.c.; lactose (milk sugar) 10 gm. When it is not convenient to analyze the milk to be used, the following formula for changing dairy cow's milk to the equivalent of human milk is very convenient and

approximately correct: Milk, 300 c.c.; water 166 c.c.; lime-water, 4 c.c.; cream, 30 c.c.; lactose (sugar of milk) 8 gm. If constipation is present and the liver is acting properly the cream should be increased; if diarrhea prevails, the cream may need to be reduced or the lime-water increased. Sometimes colic and even diarrhea result from the proteids present in the milk, in which case it may be found necessary to diminish the proportion of milk and increase that of cream and water. There are few cases which seem to fare badly on milk in any form. Some of these thrive on a mixture of cream, sugar and barley water. Not unfrequently some of the prepared foods serve every purpose, and being convenient and easy of preparation it may be entirely proper to use them; but the child must be observed closely in order to see that it is properly nourished.

If in a given case it is found that the quality of the food is normal, the second point to determine relates to the quantity the baby receives. When the quality is right, a deviation from the normal is usually toward excess. Babies are likely to be fed too much as well as too frequently. A healthy child easily rejects an over-abundance of milk without serious consequences, but if any diseased condition exists in the stomach, the vomiting becomes the symptom of pathologic changes. In a table given below I give the quantity which will meet the requirements of most cases. Variations as indicated in the table, and frequently greater variations than there given, are required. These may depend upon conditions of the stomach and the size and weight of the child. The age of the patient exerts a marked influence and must always be taken into account. It is surprising in many cases that so little attention is bestowed on the age, the weight and the condition of the child's stomach. Particularly is this true in general practice in the hands of too large a proportion of the profession.

TABLE ACCORDING TO AGE.

Age.	Temperature of food.	Intervals, hours.	No. of feedings in 24 hours.	No. of night feedings.	Amount at each feeding.		Total amount in 24 hours.	
					oz.	c.c.	oz.	c.c.
One week.	100	3	10	2	1 1/2	30-45	10 15	300-450
Two weeks.	100	3	10	2	1 1/2-2	15-60	15 -20	450-600
Four weeks.	98	3	10	2	2 1/2-3	75-85	25 -28	750-850
Six weeks.	98	3	10	2	3	90	30	900
Eight weeks.	98	3	9	1	3 1/2	105	32	960
Three months.	96	3	9	1	3 1/2-4	100-120	32 -36	960-1080
Four months.	96	3	8	1	4 1/2-5	135-150	36	1080
Five months.	90	3	7	1	5 1/2	165	38 1/2	1155
Six months.	90	3	7	0	5 1/2	172	41	1204
Seven months.	90	3	6	0	6	180	42	1260
Eight months.	90	3	6	0	7 -7 1/2	210-225	42 -45	1260-1350
Nine months.	90	3	6	0	7 1/2	225	45	1350
Ten months.	90	3	6	0	7 1/2	225	46 1/2	1395
Eleven months.	90	3	5	0	9 1/2	285	48	1440
Twelve months.	90	3	5	0	9 1/2	285	48	1440

The third point of interest in our study is the proper interval between feedings. This is shown in the table for different ages for the first year. It sometimes occurs that pathologic conditions, as acute gastritis, may require deviation from the suggestions here offered; and not only a reduction in amount, but a lengthening of the intervals may be necessary. The necessity frequently arises for rectal alimentation until the stomach has had rest. Frequent feedings with smaller amounts of nourishment, when milk is the diet, are objectionable because of the danger arising from having the stomach functionally engaged in two or three stages of digestion at the same time. In

stomachs with impaired digestive power it is frequently necessary to peptonize the milk or administer it alternately by mouth and rectum, so as to give the stomach time to complete one meal before another is given. Many cases of rachitis are due to too frequent feeding. I have met cases of anemia and subacute and chronic gastritis in children which were due to the habit of feeding at too short intervals. Care exercised in this particular will obviate many of the disturbances of infants in the first year of life. In general practice one of the most frequent vexations of the physician is to find that the mother or nurse girl is careless about the temperature of the baby's milk. If it is warmed at all, it is not warmed to a definite degree; and if it is to be pasteurized, often the matter is overdone and the milk boiled.

Artificial food for babies in the first month ought to have a temperature of 100 degrees F. After that time it may vary between 100 and the figure given in the accompanying table. The food must not be prepared and then allowed to lie about until it is cold before using. The approach to mother's milk should include temperature as distinctly as composition. As the child grows older, after three months, the proportion of water may be gradually reduced and that of milk increased, until at eight or ten months cow's milk unmodified will be borne by many children. The fact that many children survive the almost criminal negligence of their nurses in the particulars here mentioned is not of sufficient weight to justify a departure from rigorous care. The food should be sterilized, it must be of proper quality, of sufficient quantity, administered at proper intervals and be of proper temperature. In pathologic cases additional modifications may be required.

THE SURGERY OF CAMP WIKOFF.

BY N. SENN, LIEUT. COL. U. S. V.

CHIEF OF THE OPERATING STAFF WITH THE ARMY IN THE FIELD.

(Continued from page 1307).

ABSCESSSES.

We would naturally take it for granted that among the returning soldiers from Cuba, owing to their greatly debilitated condition, suppurative affections in different forms, and affecting various tissues and organs, would furnish a rich and interesting material for the surgical ward of the General Hospital. The sources of infection were many, and the resistance of the tissues to pathogenic microbes in most of the men who returned was at low ebb. A good share of the surgical work consisted in incising and draining abscesses, some of them of enormous size. In the treatment of all of these cases, owing to the pronounced anemia and great weakness, special precautions were resorted to to prevent the loss of even as much as a teaspoonful of blood in performing the operations. In abscesses in the anal region the Paquelin cautery was usually used in preference to the knife, in laying open the abscess cavity. In other regions the abscess was opened by making an incision through the skin and underlying fascia large enough to admit the tip of the little finger, when the remaining tissues were tunneled with a pair of curved, rather sharp pointed forceps, and the tubular wound enlarged to the requisite extent by expanding the blades of the forceps during the withdrawal of the instrument. In most instances a counter-opening was made by plunging the forceps into the abscess cavity, inserted into the first opening, through the tissues from within outward until the tip of the instrument made a cone of the skin which was then incised, not over, but on the side of the instrument, sufficiently to permit the easy escape of the instrument when the

canal was enlarged by expanding the blades, after which the end of the drain was grasped transversely and by withdrawing the instrument through drainage was established. The drains used were freely fenestrated, the openings being numerous, but never larger than to correspond in size to one-fourth of the circumference of the tube. The opening and counter-opening were made in places where drainage and irrigation would prove most efficient. In several cases in which the counter-opening could not be made by the use of the forceps, the abscess was opened in the usual way, and after evacuation of its contents peroxid of hydrogen was injected until the cavity was well distended, when the second opening was made in the same way as the first. After opening and draining the abscess, irrigation with a 2½ per cent. solution of carbolic acid, followed by peroxid of hydrogen, and finally again with the carbolized solution. In all abscess cases the dressing consisted of a compress of gauze wrung out of a 2½ per cent. solution of carbolic acid, over which oiled silk was applied with absorbent cotton around its edges, to act as a filter, and the whole confined in place by a well-applied bandage. In the more serious cases the dressing was removed, the abscess cavity flushed, and a new compress applied twice daily. Whenever it was deemed necessary, the affected limb was immobilized. This treatment proved uniformly successful in preventing profuse suppuration and was always followed by rapid improvement in the general condition of the patient.

In the medical treatment of these cases quinin was used freely, as well as alcoholic stimulants. Iron preparations and a nutritious diet proved most effectual in improving the condition of the impoverished blood and in restoring normal nutrition.

CONNECTIVE TISSUE ABSCESSSES.

The connective tissue was the tissue most frequently the primary or secondary seat of infection. The phlegmonous inflammation which led to connective tissue abscesses occurred almost exclusively in men whose general health was shattered. As a rule the patients suffering from this affection presented an anemic, almost waxy appearance and were greatly emaciated. The deterioration of health was due to antecedent causes, malaria, yellow fever, dysentery, diarrhea, exposure and improper or insufficient food. The phlegmonous inflammation in most instances pursued a rather insidious process and was clinically not characterized by the complexus of symptoms which ordinarily accompany the inflammation preceding an acute abscess. The pain was often slight, tenderness moderate, and the skin seldom showed the inflammatory blush which so constantly is seen during the development of an acute subcutaneous abscess. A tendency to burrowing was manifest in most cases. The induration of the abscess wall, so common in acute abscess, was lacking in most of our cases. There seemed to be a total absence of a tendency to the limitation of the area of abscess formation. The cases that came under our observation resembled in their symptomatology, pathology and clinical course very closely abscess formation as seen during the latter course of any prolonged acute infective disease, or during convalescence from such. In opening these abscesses I was always careful to make the openings some distance from the center of the abscess cavity, in preference at its margins, and the same location was selected in case a counter opening was made. By following this method of incising and draining the abscess the skin over the center of the abscess, damaged to the greatest extent by the underlying phlegmonous process was avoided, and complete evacuation and free drainage secured. The same careful preparations were made for the operation as in cases requiring surgical intervention for aseptic conditions, with a view of guarding against secondary infection.

Under this treatment, the general and local conditions of the patients improved very rapidly. In abscesses of very large di-

mensions from two to four incisions were made and as many points of drainage established. As suppuration ceased and the abscess cavity commenced to shrink, the drains were shortened from time to time to enable the process of healing to proceed without hindrance from mechanical causes.

Case 14.—Robert Bloedel, age 25, Third Infantry Band, enlisted fifteen months ago. Had chills and fever in Cuba for about a month, followed by dysentery. Is still suffering from the diarrhea which followed the dysentery and the patient is much emaciated and very anemic. Before going to Cuba he noticed a small pimple on his neck. Just before leaving Santiago, swelling of the neck began in the connective tissue, at the site of the pimple, and has progressed steadily. Examination of the cavity of the mouth does not reveal a source of infection. There can be but little doubt that the minute furuncle, which proved harmless as long as the patient remained in good health, became the focus of infection of the underlying connective tissue which was made more susceptible to infection by the effects of disease. A large fluctuating swelling in the neck, just below the angle of the jaw, marks the location and extent of the connective tissue abscess. Pain has never been severe. Edema, but no redness of skin. All of the local symptoms indicate a slow, subacute inflammation of the deep connective tissue. The patient was etherized and through drainage was established, the drainage tube being placed in an oblique direction from the floor of the abscess to a point opposite and behind. A large quantity of creamy pus was evacuated and the cavity thoroughly washed out with carbolyzed solution and peroxid of hydrogen. A large moist antiseptic compress covered with oiled silk was applied and held in place by a bandage. Very little suppuration after operation, speedy healing of the abscess cavity accompanied by a marked improvement in the appearance of the patient.

Case 15.—P. P. Sprague, age 29, Seventh Infantry, Company I, entered the regular service seven months ago. He landed in Cuba July 10. Contracted malaria, lost flesh and strength, but continued to perform his usual duties. About three weeks ago he experienced a sense of soreness in the calf of his right leg in the region of a scar from an injury received during childhood. The soreness increased slowly in severity, and for a number of days he has suffered from a throbbing pain sufficiently severe to prevent sleep. The patient is much enfeebled from the effects of the previous disease, aggravated by the recent attack of phlegmonous inflammation. No local source of infection could be found on the most careful search. It is very probable that the scar tissue furnished the *locus minoris resistencie* which determined localization of pus microbes floating in the general circulation sufficient in number and virulence to give rise to a subacute phlegmonous process. The whole leg is swollen from the ankle to the knee, tense and edematous, a circumscribed inflammatory blush over the lower portion of the gastrocnemius muscle. Fluctuation deep-seated, somewhat obscure and diffuse.

The diagnosis made at the time, was deep-seated phlegmonous abscess, involving the connective tissues between the deep-seated muscles of the leg. August 29, under ether anesthesia the abscess was opened by an incision over the posterior aspect of the leg in the median line, at a point where the muscle terminates in tendon; a large quantity of thin bloody pus escaped. As it was found impossible to make a counter-opening in the upper recess of the abscess cavity by the use of forceps, peroxid of hydrogen was injected through the opening to distend the abscess cavity sufficiently to facilitate incision from without. The second incision was made in the usual way over the upper third of the fibula and a counter opening established on the tibial side, effecting in this manner efficient through drainage below and from side to side. Digital exploration through the three openings located the abscess correctly anatomically. In exploring the interior of the abscess the tibia and fibula could be distinctly felt. The abscess cavity was disinfected in the usual way and after applying the wet antiseptic compress, the patient was returned to his cot and the limb placed in an elevated position. The final recovery of the patient was retarded by several severe attacks of malaria during one of which the mercury reached 106 F. The chills and fever yielded to large doses of quinin.

Case 16.—Henry H. Mix, age 21, Third Infantry, Company F, enlisted three months ago. On June 6 last, while on parade had an attack of heat exhaustion followed by diarrhea for several days. At Tampa, June 8, two days later, he was put on sick list for two furuncles behind the left knee. These healed promptly. July 10 on reaching Cuba, he suffered from furuncles on buttocks, also malarial fever and diarrhea. At this time an abscess formed in the right popliteal space, which pursued an insidious, chronic course. At the time the patient reached Montauk, he was very anemic and almost reduced to a

skeleton, and the abscess had opened at different points. The subcutaneous tissue was extensively undermined, and through the openings the fungous lining of the cavity could be distinctly seen. This abscess cavity discharged profusely and extended from the middle of the thigh to the upper portion of the calf of the leg. August 29, the sinuses were enlarged, a number of counter-openings made and free tubular drainage established. The abscess cavity was thoroughly disinfected and a large moist antiseptic compress applied. As there was some tendency to contraction of the knee joint, the limb was placed in a straight position and immobilized by the use of a well padded anterior wire splint so applied that the abscess could be exposed and treated without disturbing the limb. Malarial fever, which developed on the second day after the operation, retarded the healing process, and for a few days threatened the life of the patient. After the fever was under control by the administration of large doses of quinin, a satisfactory process of repair set in, which soon effected healing of the abscess and restoration of tissues lost by the extensive destructive process.

Case 17.—Joseph McGuire, Ninth Massachusetts Volunteers, Company C, had some febrile attack in Cuba, the nature of which is not known. He was admitted to the surgical department of the General Hospital, September 7, suffering from a superficial connective tissue abscess over left triceps about two inches below the shoulder joint. He has at the same time an alveolar abscess which is discharging through a carious tooth. The infection in this case evidently took place from the blood, as there are no traces of the existence of a local infection atrium to which the phlegmonous process could be attributed. Through drainage and moist carbolyzed dressing.

Case 18.—James F. Dite, age 21, First Illinois Infantry, Company H, received a severe contusion of anterior surface of right thigh from falling log near Santiago. He was treated by a Cuban doctor for rheumatism, and then sent to the Division Hospital where a swelling which had formed at the site of injury was incised, but no pus escaped. The swelling remained, and gradually increased in size. When admitted to the surgical ward his general health was precarious. Marked anemia and emaciation. The anterior aspect of the affected thigh from near the knee to the inguinal fold was the seat of a fluctuating swelling. The center of the swelling was occupied by a small granulating area marking the place where the incision was made. The abscess was underneath the quadriceps femoris muscle, and evidently the incision had not been made deep enough to reach the pus. As the skin was not broken by the injury, infection was determined by microbes floating in the circulation and their localization and growth in the contused deep connective tissue. Under anesthesia the abscess was opened at the most dependent point and a counter opening made on the opposite side with the aid of distension of the cavity by peroxid of hydrogen injection. Through drainage and thorough disinfection of the interior of the abscess cavity completed the operation. Prompt relief and improvement followed the operative intervention.

Case 19.—Dennis Riley, age 21, First District of Columbia Infantry, Company E, after passing through a rather severe attack of typhoid fever was admitted to the surgical ward suffering from multiple abscesses, varying in size from that of a pea to a walnut, involving the face and the neck. The largest abscess was above the left eyelid. All of these abscesses had their primary starting point in the subcutaneous connective tissue. Treatment by incision and drainage. Convalescence progressed without any further interruption. The location of these abscesses on the exposed part of the body would indicate that the infection had a local source, probably slight abrasions inflicted by the patient himself during the course of the fever.

Case 20.—Edwin Stockwell, aged 28, Second Infantry, Company I, was well until the day before leaving Cuba, August 10; on that day felt very weak and sick. On boarding transport had to lie down, vomited, then felt better for a time, then weak and sick and nausea and vomiting again. He was feverish all the time and slightly jaundiced, but continued on duty with the sick. Some doubt remains as to whether this attack was a mild form of yellow fever or malaria. Since his arrival here he has done duty as a nurse. Five or six days ago a furuncle developed on the middle of the posterior aspect of the right thigh, below the gluteal fold. This opened and discharged slightly, but the swelling has continued to increase in size. On examination, a crater-like defect in the skin marks the site of the primary focus of infection. From this point a red zone of inflammation extends in all directions equally to a distance of two inches. The phlegmonous progressive connective tissue inflammation had its origin from the furuncle. Such a complication would probably not have occurred if the patient's general health and power of resistance to general infection had not been impaired by the antecedent attack of fever. The

skin around the furuncle was extensively undermined. The cavity was freely laid open by a vertical incision and the necrosed tissue and infected granulations scraped out with a sharp spoon, and after thorough disinfection was lightly packed with a strip of iodoform gauze, and a large moist compress applied.

Case 21.—John A. Johnson, aged 24, Third Infantry, Company H, enlisted eight months ago. Phlegmonous inflammation of middle finger of left hand. Three weeks ago had an attack of malarial fever in Cuba, which was complicated by diarrhea. He was treated four days in one of the hospitals, when he returned to his command for duty. The fever left him in a weakened condition. Ten days ago on leaving Santiago, he noticed a soreness over the dorsal side of the middle finger of the left hand directly over the middle joint. Cause of infection not known. An acute superficial abscess formed, attended by great pain until it ruptured. A considerable portion of the overlying skin sloughed, leaving a ragged surface with edematous red margins. On August 27, the patient was placed under an anesthetic, when a thorough examination showed that the infective process did not extend to the joint or the extensor tendon. With sharp spoon, scissors and forceps the infected tissues were removed, the resulting surface disinfected and packed with iodoform gauze and the finger immobilized on a palmar splint. The wound healed promptly and the prospects are that the finger will regain its normal functions.

Case 22.—Richter, aged 23, First Illinois Infantry, Company D, contracted typhoid fever in Cuba five weeks ago. During the fever a copious herpetic eruption made its appearance on the upper lip and about the nasal orifices. The fever left him in a greatly emaciated condition. A swelling formed in the left cheek during the last three or four days and increased rapidly in size. Pain and tenderness not well marked. The patient sought medical treatment at the surgical ward Sunday, September 11. The left cheek was the seat of a large fluctuating swelling. Diagnosis made at the time—abscess of cheek. The abscess was incised from the mouth and a large quantity of very offensive pus was evacuated. The patient was directed to resort to frequent rinsings of the mouth with a saturated solution of boracic acid and was given a furlough to enable him to return as quickly as possible to his home. Infection in this case undoubtedly occurred through the skin defects left by the herpetic eruption.

GLANDULAR ABSCESS.

In the discussion of phlegmonous abscess, infection was traced either to a *portio invasionis* or local conditions, which determined localization from local causes, in cases in which it was reasonable to suppose that the essential cause of infection existed in the general circulation. Without calling attention to the fact, it is reasonable to suppose that in the first class of patients the essential microbic cause reached the tissues through the connective tissue spaces, that is, that a direct anatomic connection existed between the primary essential infection-atrium and the seat of secondary phlegmonous manifestations. In the consideration of glandular infection it is essential to connect the infection-atrium anatomically and physiologically, with the secondary glandular suppurative conditions. We are able from the clinical history and the pathologic conditions presented in most of the cases to establish such a direct connection between the primary source of infection and the secondary glandular manifestations. I have reason to believe that in most of these cases the essential cause of infection was the streptococcus pyogenes, because it is well known that this pyogenic agent usually follows either the connective tissue spaces or the lymphatic channels in giving rise to a distant infective suppurative process.

Case 23.—Patrick Collins, age 28, Company C, Eighth Infantry, enlisted one year ago. About the middle of July, while in Cuba, had a malarial chill followed by fever. Has had fever and diarrhea, and has been on the sick list ever since. While returning on transport from Cuba he experienced soreness in the region of the left parotid gland; this symptom has been followed by the usual clinical evidences indicative of the existence of an abscess in that locality. On August 29 he presented himself at the surgical ward, and at that time it was not difficult to diagnose the existence of a large abscess in the region of the parotid gland. At that time, under ether anesthesia, it was easy to recognize a diffuse abscess in the parotid region. It was more difficult to decide whether this abscess

was of malarial or typhoid origin. Two incisions were made, an extensive purulent product was evacuated, and efficient through tubular drainage was established. In this instance the whole gland seemed to be surrounded by the suppurative products and the through drain was passed underneath the gland that was the primary seat of the secondary field of infection. The patient improved rapidly after the operation.

Case 24.—John Williams, age 25, Ninth Cavalry, Troop F., colored, enlisted four months ago. Following a strain in lifting and exposure in rough weather, while on duty in the Camp at Tampa, Fla., he became aware of the enlargement of the inguinal glands on the right side. The glands were very painful when he was on active duty. There are no evidences of general infection of any kind and the most scrutinizing examination failed to detect any tangible source of infection in the distal side of the lymphatic circulation. On palpating, three or four inguinal glands were found distinctly enlarged with plain evidences of beginning perilymphadenitis, but no distinct abscess formation. On August 22 chloroform was administered and a curved incision made, with the convexity directed upward in such a manner as to expose the infected glands freely. The glands, three in number, honeycombed with pus were enucleated. A place for drainage was established, the wound thoroughly disinfected with iodoform, when the external incision was closed with sutures of horsehair. The wound healed promptly by primary intention.

Case 25.—George A. Roberts, Sixteenth Infantry, Company H., colored, was ill eight days with malaria in Cuba, was after that on duty until his arrival in Montauk, when he again had malarial fever. During this attack a furuncle developed on calf of the right leg and opened spontaneously. From this point a lymphadenitis started, which extends to the deep lymphatic glands in Scarpa's triangle and terminated in a lymphadenitis and perilymphadenitis. The lymphatic glands in this region, being in a state of inflammation, resulted in the formation of a tender and painful swelling four inches in length and about three inches in width. No fluctuation and no inflammatory discoloration of the skin. The patient was confined to his cot with the affected limb in an elevated position. A large compress saturated with 2½ per cent. hot solution of carbolic acid. Applied Credé's ointment to be rubbed into the skin over the swelling once a day. Under this treatment the inflammatory process subsided and the prospects are, that the swelling will disappear without pus formation.

Case 26.—Frederick Warner, age 37, colored, Ninth Cavalry, Troop L, contracted chancroid about six weeks ago, while on duty at Tampa. The lymphatic glands in the inguinal region became infected and the suppurative lymphadenitis terminated in the formation of three glandular abscesses, which opened spontaneously. At the time the patient was operated upon, September 1, three fistulous openings were found, and the connective tissue was extensively infiltrated. No scars or other evidences of the primary lesion can be detected. It was plainly a case of suppurative lymphadenitis, caused by invasion with pus microbes from the external genitals. Under chloroform anesthesia the sinuses were enlarged, and the remaining broken down gland tissue and infected granulations removed by a vigorous use of the sharp spoon. The resulting wound was thoroughly disinfected, iodoformized and packed with iodoform gauze and covered with a large moist antiseptic compress of gauze, over which was placed an overlapping piece of oiled silk, and the whole dressing held in place by a bandage embracing the pelvis and upper part of thigh. The patient left the hospital a week after the operation, at which time the abscess cavities were much diminished in size and lined by vigorous healthy granulations.

Case 27.—John H. Butler, age 21, Ninth Cavalry, Troop L, colored. Tubercular lymphadenitis of submaxillary gland. Family history negative. Mother and father living; two children died in infancy; rest living and in good health. About two months ago began to have pain in right side of neck and submaxillary region, and then noticed a small, hard swelling below the angle of the jaw. Additional glands in the same region became involved. At the time he entered the surgical ward a large glandular mass, composed of several enlarged lymphatic glands, was found in the right submaxillary region. On palpation the swelling was painful, but no distinct fluctuation could be felt. Inspection of the mouth failed to reveal anything which could be regarded as an infection-atrium. The tubercular nature of the glandular affection was recognized, and a radical operation for the removal of the glands was performed September 6, the patient being under the influence of chloroform. The glandular mass was freely exposed by a semilunar incision with the convexity downward and by reflection of the cutaneous flap in an upward direction. The whole

mass was dissected out in one piece, which included not only the tubercular glands, but likewise the infiltrated connective tissue surrounding them. The submaxillary gland was exposed, and during the latter part of the operation it became necessary to cut and ligate the facial artery. The gland tissue throughout had undergone coagulation necrosis; each gland contained several foci of caseation. The wound was iodiformized and sutured throughout with horse-hair, provision for gauze drainage having been made by making a button-hole near the margin and center of the flap. Healing by primary intention.

Case 28.—Schuyler C. Black, age 31, Ninth Cavalry, Troop I, colored, enlisted four months ago. Chronic balanitis and bilateral plastic lymphadenitis of inguinal glands. In June last noticed enlargement of inguinal glands on both sides, following a small sore on the glans penis near the corona. He was treated for primary syphilis, and was given large doses of potassic iodid. At no time was there any induration at the base of the sore, which always presented the appearance of an abrasion rather than an ulcer. At no time have there been any indications of secondary syphilis. The lymphatic glands in other regions of the body are normal. The patient states that the sore has healed repeatedly, reappearing at varying intervals in the same place. Examination of the penis reveals slight phimosis, chronic balanitis which has resulted in great thickening of the mucosa lining the prepuce. The sore, which has been a source of great mental distress to the patient, appears in the form of a very superficial abrasion not larger than a split pea with ill-defined margins and no induration whatever at its base. Recently the preputial margin became the seat of a herpetic eruption. The lymphatic glands in both groins are hard, not very tender to the touch and vary in size from that of a pea to a hazelnut. September 13, typical circumcision was performed under chloroform narcosis. It is expected that the removal of the direct cause of the lymphadenitis will be followed by a speedy reduction in the size of the glands. The essential cause is to be attributed to the entrance of pus microbes into the lymph channels from the local lesions of the glans penis and prepuce which became arrested in the lymphatic filters, producing an inflammation which came to a standstill short of suppuration.

Case 29.—Robert V. Smith, age 21, Tenth Cavalry, Troop E, colored, enlisted June 20. A month ago while in camp in Florida, he noticed a number of small pimples on the scalp on the right side. These small furuncles still exist, and a week ago gave rise to a deep seated lymphadenitis affecting the lymphatic glands in the superior posterior triangle on the corresponding side of the neck. When the patient came under observation, September 13, a large and somewhat diffuse swelling marked the location of the infected glands; evidently the connective tissue around and between the glands is secondarily implicated in the inflammatory process. The swelling is hard and tender on pressure. No signs of central softening. Evening temperature 102 F., morning temperature 100 F. Directions were given to clip the hair short, and to disinfect the entire scalp. Credé's silver ointment to be rubbed into the skin over the swelling and to apply a hot, moist antiseptic compress. The patient is anemic, for which condition Gude's pepto mangan was prescribed. There is some prospect that the removal of the source of infection and the local applications will succeed in arresting the process and in effecting resorption of the inflammatory product.

This hope was not realized, as a few days later, September 23, distinct fluctuation was felt and the abscess was incised and drained, the patient being under the influence of chloroform. Rapid improvement followed the operation.

ABSCESS FOLLOWING TYPHOID FEVER.

It is somewhat singular that among the hundreds of cases of typhoid fever, that I had an opportunity to see and examine in Porto Rico and in this great national camp, no cases of perforation have come to my notice. I kept myself in readiness to perform laparotomy at a moment's notice, but my services were never requested for this particular purpose. I have no doubt but that some of the deaths from typhoid fever were due to this cause, and that this fatal complication was either overlooked or the general condition of the patient was so grave when it occurred, that the attending physicians did not deem it advisable to send for the surgeon. In this camp we had all the necessary facilities for abdominal operations, and I was hopeful that I should have an opportunity to give surgery a fair trial in such cases, but in this I have been disappointed. The most important, and most frequent complications of our typhoid fever pa-

tients have been bedsores and abscesses. The careful and attentive nursing our patients here have received, has done much in reducing the mortality and suffering from decubitus. Frequent washing with alcohol of the parts exposed to decubitus and the use of rubber pillows, and in the worst cases, of water or air beds, have contributed much in the prevention and successful treatment of this complication. We have had however, an excellent opportunity to study the etiology and pathology of abscesses as a complication of typhoid fever. The material was abundant and interesting. It is a source of regret to me that we did not have at our disposal a well-equipped bacteriologic laboratory to enable us to study in a more satisfactory manner the contents of those abscesses. Acting Assistant-Surgeon Ewing brought his own microscopic outfit, including the different stains, and did good work in the microscopic examination of pus and other pathologic products, but we had no facilities for making cultures. He examined the contents of three abscesses in as many patients, and found as the essential bacteriologic cause the bacillus of typhoid in one and the ordinary pus microbes in the remaining two cases.

The typhoid or so-called metastatic abscesses are caused by the bacillus of typhoid fever or by pus microbes which find their way into the circulation through some infection-atrium, especially the intestinal ulcers, as the result of a mixed infection. I have no doubt that in some cases the colon bacillus finds its way into the general circulation and produces the same results. The only case of bone and joint infection that came under my observation, and that could be brought in connection with the typhoid infection occurred in the case of a young soldier recovering from a severe attack of typhoid fever.

Case 30.—William Fairweather, age 22, Company A, Twelfth Infantry, about one week after the surrender of Santiago, was attacked with fever which continued for three weeks. He reached this camp with his regiment, emaciated to a skeleton, and extremely anemic. A week ago, while moving about, he was attacked rather suddenly with a severe pain in the right sacro-iliac synchondrosis and extending to the leg on the same side. The pain in the leg subsided after a few days but increased in severity at the point where it first commenced. The pain is of a dull, aching, throbbing character. Slight swelling over and in the line of the joint. Evening temperature one degree above normal. No redness or edema of the skin. September 6, the joint was punctured with the largest needle of an exploring syringe and a 5 per cent. solution of carbolic acid was injected in different directions, so as to reach the infected tissues as far as possible. No difficulty was met with in injecting three drachms of the solution. The needle puncture was sealed with collodion and a pledget of cotton. Marked improvement followed the intra articular and parenchymatous injection. The pain and tenderness had nearly disappeared on the third day. Under tonics and stimulants the general condition of the patient improved from day to day. There is no reason to fear at this time that suppuration will take place.

This case represents one of those rare complications of typhoid fever in which a joint becomes the seat of secondary infection during the latter stages of typhoid fever or during convalescence, in which the inflammatory process often results in great destruction of tissue without pus formation. Whether or not the injection should be credited with having brought about the speedy cessation of active symptoms can not be decided, either way with any degree of positiveness. I have learned to value the therapeutic effect of parenchymatous injections of carbolic acid in the treatment of chronic or subacute inflammation of a non tubercular inflammation, and I am inclined to attribute to it in this particular and similar cases positive curative properties, the evidence of which in this case appeared so shortly after it was made.

Case 31.—C. H. Baker, aged 22, Company F, Second Massachusetts Infantry, was sick two months in Cuba with fever, malaria, headache, anorexia, diarrhea, in consequence of which he became very weak. Shortly after boarding the transport, he became delirious and has been sick with typhoid fever for three weeks. A week ago, while convalescent, he was attacked suddenly with violent pain in the right testicle which rapidly increased in size, reaching the dimensions of a small orange in

the course of two days. At that time, the temperature increased two degrees above normal. On the third day after the attack, the swelling was hard, very sensitive to the touch, the skin red and glossy. No chills. Under applications of lead water and opium the pain has been somewhat mitigated and the swelling slightly diminished in size. September 10, a week after the complication had set in, the patient was transferred to the surgical ward. At this time deep-seated fluctuation could be distinctly felt over the center of the swelling. Less discoloration of the skin than a few days ago. Swelling only about twice the size of the normal testicle. The abscess appears to occupy the center of the testicle. Under ether anesthesia the abscess cavity was opened at the most dependent point, and a counter-opening two inches higher up made by tunnelling the tissues from within outward with a curved hemostatic forceps, and through drainage established. The pus was of the consistency of cream and whitish in color. No transudation into the tunica vaginalis. The conditions revealed at the time of operation left no doubt regarding the parenchymatous central origin of the abscess. Microscopic examination of the pus removed showed typhoid bacilli in great abundance as the exclusive bacteriologic cause of the suppurative orchitis. The patient improved very rapidly after the operation, and was transferred in less than a week to one of the Boston city hospitals.

Case 32.—L. Gardner, age 38, Company A, Sixth Infantry, went through the Cuban campaign with two days' slight illness. He lost flesh, but felt well until he came on the transport four weeks ago, when he was attacked with fever which proved to be typhoid complicated by malaria as shown by the erratic temperature curves. Convalescence was preceded by inflammation of the left parotid gland. Emaciation marked. Spleen much enlarged. The liver dullness extends from the sixth rib to an inch below the costal arch. Lungs normal. Heart sounds clear and distinct. Pulse strong and regular. Tongue red and glazed. A week after the beginning of the attack, a large abscess had formed and fluctuation could be distinctly felt, extending from a level with the external meatus to near the angle of the jaw. At that time, September 7, the patient was etherized, the abscess opened at the lowest and highest points, and through drainage established, a large quantity of thick purulent, curdy pus escaped. The cavity was washed out with a 2.5 per cent carbolic solution and peroxid of hydrogen, and a large, moist, hot antiseptic compress applied. Improvement followed at once and ended in a slow recovery without any interruptions.

Case 33.—Patrick Collins, age 26, Eighth Infantry, Company C, has been in the service one year. About two weeks after the fight in Cuba was attacked with malaria, which was followed by typhoid. The fever has persisted since, attended by diarrhea and other symptoms indicating its nature. While on the transport on his return he complained of a sense of soreness in the left parotid region, followed by swelling and redness. Patient much emaciated and very feeble. At the time the operation was performed, August 29, the swelling extended from the external ear to near the angle of the jaw, and deep-seated fluctuation was distinct. Incision, drainage, disinfection and after-treatment the same as in the preceding case. Owing to the marked weakness of the heart's action, the patient was given two ounces of whisky before he was placed under the influence of ether. Alcoholic stimulants were administered in large and frequently repeated doses and acted very promptly in increasing the tone of the circulation and in building up the impaired nutrition. The discharge from the abscess in this, as well as the other cases of abscesses of the parotid following typhoid fever, was very slight after the evacuation of the abscess contents.

Case 34.—Harold Robinson, age 28, Third Infantry, Company D, contracted typhoid fever in Cuba. He is now in the third week of the fever and has been delirious most of the time. The disease pursued almost from the beginning a very malignant course. About five days ago a swelling was detected in the region of the right parotid gland, which increased very rapidly in size, involving the skin after two or three days. The abscess ruptured on the fourth day into the external meatus, but evacuation was incomplete on account of the existence of several separate compartments in the abscess cavity, which were discovered at the time the operation was performed. The abdomen is intensely tympanitic, the skin of feet, legs and abdomen spotted with dark points of ecchymosis. The condition of the patient was critical when the operation was performed, September 10. The operation had to be performed without an anesthetic and in his ward, as he was too feeble to justify his transfer to the surgical ward. The impoverished condition of the blood made it necessary to make the incision only through the skin, completing the opening with hemostatic

forceps. Free tubular drainage was established and the abscess cavity was treated in the usual way. Strychnia and alcoholic stimulants were administered freely, but the heart failed to respond and the patient died the next day. Notwithstanding that the openings were made largely by the use of blunt instruments, free oozing of blood followed the operation, which may have contributed in hastening the fatal termination.

Case 35.—Giles Potter, age 33, Second Massachusetts Infantry, had chills and fever while in Cuba, but was on duty continuously. Was still weak and ill when he came on board the transport. The parotid abscess began on transport. He is very weak and emaciated, at times delirious; temperature indicates typhoid fever. Conjunctivæ slightly jaundiced. Pulse small and thready. Spleen slightly enlarged. The abscess was incised and drained without the use of an anesthetic, in its stead a large dose of whisky was given. The pus in this case was of a green color. Patient improved rapidly after the operation and is now on the way to convalescence.

Case 36.—John Simpson, age 28, Troop K, First Cavalry, was admitted to the general hospital August 25, suffering from typhoid fever, with a temperature gradually declining until September 4, when it rose suddenly from 99.4 to 102 and 103, dropping on the 8th to 99. On admission patient had very marked roseolar eruption on abdomen and limbs. During the course of the fever numerous furuncles appeared on the forehead and back. Delirium has been a prominent feature in the case almost from the beginning. Directly following the sudden rise of temperature on September 4, soreness and swelling of the right submaxillary gland were noticed. Today, September 10, a fluctuating swelling, the size of a small apple, marks the location and size of the abscess. Operation without anesthetic. Incision, counteropening, tubular drainage, irrigation with peroxid and carbolic solution, wet carbolic dressing. Rapid improvement followed the operation and the patient is now, September 13, fairly convalescent; abscess nearly healed.

The parotid gland, of all glandular organs, is the most frequent seat of secondary infection in typhoid fever. For reasons that remain unexplained the submaxillary is seldom involved, and the sublingual is still more rarely affected. The infective process begins in the parenchyma of the salivary gland but extends rapidly to the capsule and the surrounding connective tissue, leading to a phlegmonous process which in four or five days, as a rule, terminates in a well-marked abscess with the gland as a central point. The physician must be on the alert in such cases, and resort to the use of the knife in a most cautious manner as soon as fluctuation can be detected. It is advisable to establish through drainage for the purpose of securing free evacuation and thorough disinfection of the interior of the abscess cavity. The openings should be made by cutting only the skin and underlying fascia with the knife, completing them by tunnelling the remaining tissues with a curved hemostatic forceps. Dry dressings should not be employed in such cases; nothing is more grateful to the patient and more efficient in the after-treatment than the application of a moist, hot, antiseptic compress covered with oiled silk to retain heat and moisture. The safest and most efficient solution for this purpose is a saturated solution of acetate of aluminium, but when this can not be secured, a 2.5 per cent. solution of carbolic acid or a saturated solution of boracic acid answer as excellent substitutes.

In the next case the clinical history is very defective, and it is impossible to say with any degree of certainty whether or not the parotid abscesses followed in the course of typhoid fever, or whether they were external manifestations of a general septic process that developed independently of that disease.

Case 37.—Austin Dunlap, age 19, Company H, Third Infantry, was taken suddenly ill in Tampa, about July 1, with pain in the back and joints and nausea. The disease was diagnosed at the time as malaria. He was sent to quarters, and after four days returned to duty. On arrival at this camp, August 14, had three severe chills during the first twenty-four hours and has been very sick since. When admitted to the surgical ward with bilateral suppurative parotitis and large bedsores, he was reduced to a skeleton. Extensive herpes labialis which near the left angle of the mouth have caused ulceration; abscess over elbow joint. Pulse rapid and very

small, temperature irregular. When first admitted the case was regarded as a forlorn one and whiskey was given in ounce doses hourly. The swelling in the parotid region, on both sides, was hard and very sensitive to the touch. Credé's silver ointment and hot antiseptic compresses constituted the local treatment. Five days later distinct fluctuation could be detected and one of the parotid abscesses was incised and free tubular drainage effected. Owing to his critical condition the operations had to be performed without an anesthetic. The next day, September 10, the opposite abscess was treated in the same manner. The patient has been placed on a water-bed and was restless and most of the time delirious. No evidences of metastasis in any of the internal organs. Under the stimulating treatment he rallied promptly and at the present time, September 13, his mind is clear and the temperature normal. Discharge from abscess cavities slight. The drains are shortened from time to time to permit early definitive healing of the abscesses.

I am confident that early operative treatment and the heroic employment of alcoholic stimulants have been the principal means in saving the life of this patient.

Case 39.—Corporal George F. Shilling, age 18, Company G, First D. C. Volunteers. Enormous typhoid abscess of arm. Family history negative. Health excellent before he went to Cuba. On August 15 reported sick at the hospital. Had been feeling ill for some days. He has been delirious most of the time since admission to the General Hospital here. The temperature has been on an average 103 degrees F., with daily variation of a degree and a half from August 19 to September 4. Since latter date the temperature at no time has been over 101 degrees F. The pulse is small, rapid and weak, tongue dry, brown and fissured. On arriving here on transport there were five large bedsores on back and numerous small abscesses of the skin. He was placed at once upon a water-bed, but the bedsores continued to still further undermine the skin. Two days ago when the nurse was dressing the bedsores, she discovered a swelling of the right arm on the outer edge of the biceps muscle. This has rapidly increased in size and now presents itself as an enormous abscess extending from the shoulder to the tendon of the biceps muscle. Fluctuation is most distinct over the outer aspect of the arm. On palpation a crackling sensation is felt, and on percussion the swelling was distinctly tympanitic. The presence of gas in the abscess cavity could not be doubted. September 12 the patient was almost pulseless, lips cyanotic, respiration shallow, and marked twitching of the muscles of the upper extremities. In the afternoon the abscess was cautiously opened above and below and a rubber drainage tube drawn through. A large quantity of an offensive gas and creamy pus was evacuated. The abscess cavity was freely irrigated with peroxid of hydrogen and 2.5 per cent. of carbolic solution and the moist, hot antiseptic compress applied. In place of an anesthetic the patient was given an ounce of whiskey, which was to be repeated hourly. Hot water bags were applied to relieve the embarrassed peripheral circulation. Contrary to our expectations, the patient rallied under this treatment and presented a much more encouraging condition the next morning, when it was reported that the temperature was nearly normal, mind clear and the pulse full and strong. Microscopic examination of the pus by Dr. Ewing revealed: 1. many cocci resembling staphylococcus pyogenes; 2. a few large capsulated cocci; 3. a few fine slender bacilli staining faintly with methylene blue. There is nothing that resembles the bacillus aerogenes capsulatus. The patient is in a fair way to recovery (September 17).

Case 40.—Fred Angier, age 23, First Cavalry, Troop I, is under treatment for typhoid fever probably during the third week of his illness. Patient is delirious and it is impossible to obtain reliable information as to duration of his sickness. Very recently the right eye became affected by an acute inflammatory process which appears to involve all of the tissues of the organ. The eyelids are swollen, red and somewhat edematous. The edema extends over the whole malar region. Exophthalmus well marked. Pupil contracted and immovable. Conjunctiva in a state of catarrhal inflammation. Hypopion. Sent to the New York Hospital, August 30, for treatment by specialist of the eye complication. This is the only case of secondary infection of eye of a typhoid character that was observed in the camp. It was a well-marked case of panophthalmitis and if the patient recovers it will be with the loss of the affected organ.

(To be continued.)

THE SANTIAGO CAMPAIGN.

MEDICAL EXPERIENCE WITH THE RETURNED SOLDIERS
OF THE DISTRICT OF COLUMBIA U. S. V.
REGIMENT.

BY LOUIS KOLIPINSKI, M.D.

WASHINGTON, D. C.

The following medical histories of soldiers of the District of Columbia U. S. V. Regiment which were gathered whilst treating these cases after their return to Washington, D. C., may be of interest for several reasons. The testimony shows with uniformity and consistency that the health of these men remained good at Camp Alger, at Chickamauga, at Tampa, on the voyage to Cuba and in the eight days spent in the trenches in front of Santiago; that they first became sick after having been encamped on San Juan hill four or five days or more and that there they were the victims of malarial fever—intermittent or remittent—accompanied or followed by diarrhea; that none of them contracted typhoid fever in Cuba, and that this infection occurred on the transports returning them to the United States or more probably after their arrival at Montauk. The following itinerary—furnished by the commanding officer, Colonel Harries—is necessary for comparison with the records of the cases:

Regiment mustered in May 17, 1898: left Washington (Camp Alger) May 21; left Chickamauga May 23; arrived at Tampa June 1; embarked for Cuba July 2; landed July 10; to the front July 11; in the trenches to July 19; on San Juan hill July 19; embarked for Montauk. Second and third Battalions, August 19; First Battalion, August 23; arrived at Montauk, Second and Third Battalions, August 26; First Battalion, August 28; regiment left for Washington, D. C., September 8; arrived September 9.

Case 1.—A. S., Company B, First Battalion. At Camp Alger, Chickamauga, Tampa, and in the trenches in front of Santiago was in good health. First became sick with a fever on the fourth day of the encampment on San Juan hill. Was not fit for duty whilst remaining there. His fever was accompanied with a severe diarrhea lasting ten days. On the transport returning was very weak for want of food. On the second day of the stay at Montauk had a chill and fever. Has not been sick before since early childhood and has not had typhoid fever.

On examination Sept. 16, 1898, midday temperature 102 degrees F.; exquisite malarial anemia; splenic enlargement. Ten grains of quinin muriate daily. September 17, temperature normal; feels much better. September 23, anemia almost gone.

Case 2.—F., 25 years, Company A, First Battalion. Has not had typhoid fever. Was sick one day only at Tampa on account of diarrhea. Next on the tenth day of the encampment on San Juan hill, fever and diarrhea. Was off duty one day. The diarrhea continued after his fever had disappeared. Drank the unboiled water from the San Juan river. At Montauk diarrhea and fever for three days. Marched in the review of the regiment on its return home. Sept. 20, 1898, E.T., 102 degrees F.; much sweating; diarrhea; spleen enlarged and tender. Appearance: Marked malarial anemia. Ten grains quinin muriate daily. September 21, afternoon, normal temperature; diarrhea continues. He soon recovered.

Case 3.—A. H., Company F, First Battalion. At Tampa drank boiled water; had there a mild diarrhea; at San Juan hill occasionally fever at night. Had from ten to fifteen diarrhetic movements daily; drank muddy, unboiled water. At Montauk remained well except some fever for a single night. H. had typhoid fever under my care in 1893. He came back looking tanned and well—a contrast to the others. He took 10 grains quinin muriate as a prophylactic, beginning this on the fifteenth of August. September 18 and 19, light fever; quinin muriate. September 21, is well, his evening temperature sub-normal.

Case 4.—M. A. G., Company A, First Battalion. At Tampa

fever and diarrhea one week before they left. Gained in weight at Tampa. On the transport and in the trenches his health was good. The fourth or fifth day on San Juan hill had chills; fever and diarrhea for thirteen days. The same symptoms continued on the transport homeward. He ate nothing. Remained at Montauk two days and arrived home September 1. Marked malarial anemia; is starved; diarrhea; undigested stools; intestinal cramps. Spleen enlarged and tender. Morning temperature 102 degrees F.; quinin muriate and copper sulphate. September 3, temperature normal; diarrhea arrested. Had four febrile relapses in September and part of October. In the second relapse severe splenic pain and tenderness simulating pleurisy. With all this, rapid recovery of color and weight. Never has had typhoid fever.

Case 5.—Sergeant L., Company E, Second Battalion, became sick, for the first time, on the seventh day, on San Juan Hill; vomiting, diarrhea, fever—no chill; fever lasted three days; was off duty two days. The diarrhea ceased at the end of one day. Drank unboiled water. At Montauk had fever, headache, and pain in the back. Was sick four days, but not in the hospital. Marched in the review of the regiment on its return.

September 19 comes to be treated for malaria. Limp feeling; headache, loose bowels; had fever yesterday; today, normal temperature. Looks thin; skin brown; not anemic. Original weight 168 pounds; has lost 25 pounds. Spleen not enlarged. Quinin and copper; rapid recovery.

Case 6.—R., Company K, Second Battalion. First taken sick on the third or fourth day, on San Juan Hill. In hospital two days; daily chill for three or four days; symptoms recurring returned to hospital; had chills followed by diarrhea lasting ten days. Drank boiled spring water. At Montauk had a cold in the head. Was too sick to march in the review on account of fever and cold in the head. Did military duty at Montauk. Has not had typhoid fever. Was never sick before entering army.

September 14, heavy chill; temperature, 104F. September 15, temperature normal. Exquisite malarial anemia. Spleen slightly enlarged. Rapid recovery.

Case 7.—Sergeant G. J. M., Second Battalion, Company K, seventh day on San Juan Hill had fever for six or seven days—mostly at night. On the fourth day of the fever, diarrhea, lasting one week; occasional recurrence of fever. Arrived in Washington August 20. Is much reduced; looks like many of the others, sad and pathetic. Has diarrhea. Quinin and copper, regulated diet; rapid recovery. In Cuba drank river water; later, boiled water. Has not had typhoid fever. Did not take quinin as a prophylactic.

Case 8.—Corporal J. A. O'N., Company A, First Battalion. At Tampa some diarrhea. On the transport, outward, was sick one day. On San Juan Hill had malarial fever for three or four days with a mild diarrhea. Drank unboiled water. Marched in the review September 9.

September 10 diagnosis typhoid fever. It ran a mild course; one relapse without symptoms becoming intensified. Recovered in twenty-four days.

Case 9.—A. F. N., Company A, First Battalion. The tenth day on San Juan Hill fever for five or six days and diarrhea for three or four days. Second attack two weeks later. Drank unboiled water from the San Juan river and from a spring. Was two days at Montauk; while there had fever. September 5, typhoid fever, mild; one relapse, also mild. Recovered October 7.

Case 10.—W. S., Company A, First Battalion. Tenth day on San Juan Hill, tertian intermittent, alternating with diarrhea, and lasting two or three weeks. Sick with fever and diarrhea on the transport homeward. Was on the sick list at Montauk. Marched in the review September 9.

September 12, typhoid fever; mild form. Recovered October 16.

Case 11.—Corporal B., Company L, Second Battalion. First sick the second day on San Juan Hill. Fever, followed by diarrhea; from four to six movements daily. This continued, but ceased spontaneously the second day on the transport homeward. Drank unboiled spring water. His diarrhea he said was endemic, and also amongst the Cubans. On the transport he was well and did double duty. His present fever developed at Montauk on the fourth or fifth day. Was able to march in the review of the regiment in this city. September 10, evening temperature 99F. Quinin has no effect.

September 12 typhoid fever begins and runs a mild course of three or four weeks. In this time one relapse, but symptoms not accentuated.

Case 12.—Sergeant F. A. C., Company M, Third Battalion. Diarrhea on transport to Cuba and in the trenches; indigested one day. On San Juan Hill diarrhea returned and lasted

one week. At the end of second week there, fever of five or six days duration. Then returned to duty. On transport home bound, sick two days with intermittent fever. Arrived at Montauk well. Five or six days later, fever and diarrhea, lasting three days. Arriving in Washington, was not able to stand or walk alone. Examined on the second day of his return. Morning temperature 103F. Pronounced picture of starvation and collapse. Fully developed typhoid fever of severe type; no relapse. Recovered second week in October.

THE WORK OF THE ARMY MEDICAL DEPARTMENT DURING THE SPANISH WAR.

Abridged from the Annual Report of the Surgeon-General.

MEDICAL OFFICERS.

The number of medical officers, 192, allowed by law, to the army is inadequate in time of peace. The insufficiency in time of war was met by the assignment of over 650 contract surgeons under the provision of the Act approved May 12, 1898. All volunteer regiments had three medical officers appointed by the Governors of States. Volunteer surgeons to fill the staff positions authorized by the Act approved April 22, 1898, were appointed by the President: Eight corps surgeons with the rank of lieutenant-colonel and 110 division and brigade surgeons with the rank of major; 5 of the former and 46 of the latter positions were filled by the appointment of officers of the Army Medical Department. The President also appointed three medical officers for each of the regiments of U. S. volunteer infantry, cavalry and engineers. The very small proportion of medical officers having experience of a military character impaired the efficiency of the department at the outset, but many of the staff surgeons from civil life showed great aptitude for the service, and speedily became of value as administrative and sanitary officers.

HOSPITAL CORPS.

No provision was made for hospital-corpsmen for the volunteer troops except that which empowered the Secretary of War (Act March 1, 1897,) to enlist as many privates of the hospital corps as the service may require. To provide this corps with the necessary number of men, recruiting officers were urged to secure suitable medical officers to effect the transfer of men from the line of the Army. General Orders No. 58, Headquarters of the Army, A. G. O., May 31, 1898, authorized the transfer of men from the line of the volunteers to the hospital corps of the regular Army upon the recommendation of the chief surgeon, and suspended the provisions of army regulations governing the hospital corps so far as they were inapplicable in time of war and with troops in the field. Commanders of corps and of independent divisions and brigades were charged with the full control of the transfer from the line, the enlistment and discharge of members of the hospital corps, the detail of acting hospital stewards and the appointment of stewards, the last limited by subsequent orders to ten stewards for an army corps in addition to those authorized for the volunteer regiments. The number of men enlisted and transferred during the war was approximately 6000.

CONTRACT NURSES.

The want of a sufficient body of trained hospital-corps men necessitated the detail of enlisted men from the regiments for hospital duty in several of the camps, and the employment of trained nurses at the general hospitals. Foreseeing the necessity for a large force of the latter I applied to Congress, April 28, 1898, for authority to employ by contract as many nurses as might be required during the war. This was promptly granted. Over 1700 female nurses have been employed, at first at the general hospitals and later at the field division hospitals, when it became evident that the field service purposes for which the latter had been originated would have to give place to the imperative need of caring for the many sick men coming from the regimental camps.

MEDICAL AND HOSPITAL SUPPLIES.

Immediately upon the declaration of war, April 21, steps were taken to obtain medical supplies for the new volunteer army. Orders were given and the manufacture expedited with the utmost dispatch. On May 3, foreseeing that it would be impossible to have ready for issue to the volunteer regiments as soon as they were mustered in, the necessary articles of field equipment, I telegraphed the Governors of the several States for authority to use the medical equipment of the National Guard in the service of the State until the Army medical supplies were ready for issue. Most of the Governors who had field equipment responded promptly and satisfactorily, but unfortunately many of the State medical department had no

such equipment. Meanwhile the officers in charge of the medical supply depots were directed to make arrangements so that supplies could be immediately obtained for 100,000 men for six months.

A field-supply table was prepared and approved by the Secretary of War, May 9, 1898. It was intended to provide for the needs of commands in active service where only a limited supply of articles could be carried, owing to the necessity of restricting transportation. But as soon as it was evident that the troops were likely to be retained in camps of instruction, notification was given that articles on the regular supply table could also be obtained.

To provide temporarily for volunteer regiments, supplies of medicines, instruments, hospital stores, stationery and miscellaneous articles, according to a prescribed list and packed in convenient boxes, were prepared at the supply depots. An important article to be provided was the first-aid packet, containing antiseptic dressings for immediate use in emergencies and intended to be carried by each individual soldier. These were promptly and liberally supplied. Whenever notice was received from the Adjutant General's office that commands were to be moved or camps formed, I endeavored to anticipate the wants of the troops by telegraphing to the officer in charge of the nearest supply depot to forward supplies for the stated number of men according to the field supply table.

Requests from the medical officers for supplies and orders based thereon transmitted to the supply depots were largely by telegraph; and orders were given that when the supplies were needed promptly they should be forwarded by express to their destination. When a medical officer desired to purchase medical and other supplies for use in emergencies authority to do so was always granted.

The medical supply depot in New York supplied the posts in New England, the Middle States and along the Atlantic Coast, including Florida, and the troops that have been sent to and are now serving in Cuba and Porto Rico. The depot at St. Louis, Mo., supplied the States of the Mississippi Valley and the region east of the Rocky Mountains, including Texas, the large camp at Chickamauga and the camps formed at Knoxville, Lexington, Anniston, Huntsville, etc. To provide for the large aggregation of troops at Chickamauga, Ga., a sub-depot, drawing its supplies from St. Louis, was organized. The officers in charge of the depots at New York and St. Louis were directed, July 8, to keep in stock 1000 iron beds or cots with a full supply of bedding ready for immediate use. The distance of San Francisco from the center of the Government was so considerable that the officer in charge of that depot was necessarily given large discretion in the purchase of supplies and the expenditure of funds.

RAILROAD AMBULANCE TRAIN.

On June 16 a railroad ambulance train, consisting of ten tourist sleepers, a dining-car, a private car and a combination car was equipped for service and placed under the command of Major Charles Richard, surgeon, U. S. A. One assistant surgeon, two stewards, twenty privates of the hospital corps and three civilian employes were assigned to him for service. The train was amply provided with all the medicines, hospital stores and comforts required for the patients to be transported.

HOSPITAL SHIPS.

The Relief.—On April 15, 1898, I applied for a ship to be used as a hospital ship. On May 18, by direction of the President, the *John Englis* was purchased and the quartermaster's department took charge of her to prepare her for the special service required. Major George H. Torney, surgeon, U. S. A., was placed in command of the ship. Specific instructions were sent to him to provide everything needful, so that there might be no delay attributable to the medical department, and these instructions were complied with to the letter. *The Relief*, however, was unable to sail from New York until July 2. She arrived at Siboney July 7, where she received many of the wounded from the attack on Santiago.

The Missouri.—On July 1, 1898, Mr. B. N. Baker, President of the Atlantic Transport Line, Baltimore, Md., tendered the steamship *Missouri*, with her captain and crew to the Government as a hospital ship. Ten days or two weeks was estimated as needful to permit of making the necessary alterations and providing the vessel with a steam laundry, steam sterilizing apparatus and ice and carbonated plants, but it was not until August 23 that the ship was reported ready to sail, and even then a good deal of work had to be done on board during a stormy passage to Santiago.

The Olivette.—This vessel was a steamship which had been doing service as a water-boat for the fleet of transports when Lieutenant-Colonel Pope, chief surgeon of the Fifth Army

corps, selected her for use as a hospital ship during the voyage from Tampa to Santiago. The equipment of one of the field division hospitals of the corps was used in outfitting her. The *Olivette* answered her extemporized purpose excellently.

THE HEALTH OF THE TROOPS.

In my opinion, the reduction of the age limit from 21 to 16 years and the haste with which the volunteer regiments were organized and mustered into the service were responsible for much of the sickness which was reported in the early days of their camp life. All military experience shows that young men under 21 years break down readily under the strain of war service; and every regiment had many of these youths in its ranks. Medical examiners were appointed to testify to the physical qualifications of each man before acceptance, but notwithstanding this, which at the time was characterized in the press as a very rigorous procedure, so many were afterward found on the sick lists of the camps unfit for service, from causes existing prior to election, that special arrangements had to be made for their discharge.

Soon after the newly raised levies were aggregated in large camps sickness began to increase progressively from causes that were so general in their operation that scarcely a regiment escaped from their harmful influence. These causes may largely be referred to ignorance on the part of the officers of the principles of camp sanitation and of their duties and responsibilities as regards the welfare of the enlisted men in their commands. Medical officers, as a rule, were also without experience in the sanitation of camps and the prevention of disease among troops. The few who knew what should be done were insufficient to control the sanitary situation in the large aggregations of men hastily gathered together. Officers and men in these camps were rife for war; and drill, parades, practice marches and military camp duties occupied the whole of their time and energies. Considerations of domestic economy and sanitation in the companies and regiments were not given proper attention, and men who were being taught to meet the enemy in battle succumbed to the hardships and insanitary conditions of life in their camps of instruction.

The sites of certain of the camps have been instanced in the newspapers as the cause of the sickness which was developed in them; but a review of the whole situation shows that it was not the site, but the manner of its occupation which must be held responsible for the general spread of disease among the troops. On April 25, 1898, foreseeing the likelihood of insanitary conditions in the camps of our newly-raised troops and with the view of preventing them, I issued Circular No. 1 from this office, impressing upon the medical officers their responsibility in sanitary matters and the necessity for a strict sanitary police, particularly in the care of the sick and in the preservation of the camp area from contamination. But the density of the military population on the area of these contracted camps prevented the possibility of good sanitary condition. Camps of this character may be occupied for a week or two without serious results, as in the case of national guardsmen out for ten days' field practice during the summer, but their continued occupation will inevitably result in the breaking down of the command by diarrhea, dysentery and typhoid fever.

Practically nothing was done to make the men comfortable or to remedy the insanitary conditions until these were brought to the attention of the Secretary of War by inspectors sent out by special orders from the War Department. Then the camps held for so long were abandoned, but not before the manifestations of typhoid infection were rife in them. New sites were carefully selected, regimental camps were expanded, company tentage increased and board flooring provided. Then, for the first time, the troops went into camps suitable for continued occupation.

One prominent cause of the increase of sickness in the early camps has been commented upon by only a few of our medical officers. These cite the prevalence of drunkenness and of venereal diseases due to the facilities and temptations afforded by the proximity of cities to the larger camps. They hold that if the systems of the men had not been weakened by dissipation they would not have succumbed so readily to the other influences which affected them. Malarial fevers added to the sick lists of camps in Florida, and of southern regiments in Georgia and Virginia. It was, however, typhoid fever which broke down the strength of the commands generally, the outbreak becoming distinctly manifest in July. Sporadic cases appeared in most of the cases in May and June, these cases having been brought in many instances from the State camps. In fact, some regiments, as the Fifteenth Minnesota, suffered more from the disease at their State rendezvous than any of the regiments in the large Federal camps. A few of the regi-

mental camps in the latter may be said to have escaped visitation. The sanitary conditions affecting the commands in the various camps have been studied in connection with the prevalence of typhoid fever among the men by a board of medical officers consisting of Majors Reed, Vaughan and Shakespeare, but the results of the investigation of this board have not as yet been reported in full. It appears to me, however, from a general review of the sanitary reports already filed, that the prevalence of the disease was proportioned to the insanitary camp conditions which I have referred to. My Circular No. 1, already cited, was intended to bring the danger from this fever to the notice of medical officers with the view of obviating it. The probability of its communication to soldiers in camp through the agency of flies was pointed out as a reason for insisting on a sanitary police of the strictest character.

It is well known to the medical profession that this fever is propagated by a contaminated water-supply, and it is not recognized that the great prevalence of this disease in an aggravated form in the camps of the Civil War was due to the use of surface and shallow well waters infected by typhoid excreta. To prevent transmission by the water-supply, I recommended the use of boiled and filtered water when a pure spring supply could not be obtained, and to enable an efficient filtration of suspected waters to be made, field filters of approved construction were issued on my recommendation by the quartermaster's department.

CARE OF THE SICK AND WOUNDED.

As soon as the regiments were organized into brigades and divisions preparatory to active service it became the duty of each chief surgeon of an army corps to see that the medical department of his command was organized to meet the casualties of battle. The object of the concentration of the troops was to accustom the regiments to operations in which they constituted the units of a higher organization. The experience of the Civil War demonstrated that for efficient service in an active campaign the medical department also required a higher organization. Circular No. 3, from this office, dated May 18, 1898, in specifying the duties of the various medical officers in an army corps, indicated the character of the organization to be adopted. The seriously sick were to be treated in division field hospitals (unless their transfer to a general hospital was advisable) under the care of the most experienced physicians and able surgeons on duty with each division. Medical officers left on duty with their regiments were to exercise sanitary supervision over the well men and determine whether a soldier reporting himself sick should be sent to hospital or remain as a trivial case under treatment in quarters. This consolidation of the medical force by divisions, involving as it did, the breaking up of the regimental hospitals, met with a strong opposition from regimental medical officers, particularly from those who were not detailed for special service at the division hospitals. Regimental commanders also were in many instances opposed to it, forgetful that the object of the medical department as of the line, was to get into training for field service. Similar objections were raised in 1862 and 1863 to the establishment of the division hospitals, but the Civil War lasted long enough to demonstrate the superiority of this system.

THE FIFTH ARMY CORPS.

Long before this corps embarked for Cuba its field hospitals were in condition for efficient service. Subsequent events, however, rendered valueless these preparations of the medical department. When the command embarked on the transport vessels, the baggage wagons and mules were left behind. The ambulance trains of all the divisions with a large part of the outfit of each of the hospitals were also left behind. Three ambulance wagons were taken apart and stored on one of the vessels. These did excellent service at San Juan and El Caney. Ten of the ambulances of the Third or Reserve Divisional Hospital were subsequently shipped to Cuba, where they arrived July 2, and were of value in moving the sick and wounded to the hospital at Siboney and to the hospital ships and transports. Of the property and supplies carried to Cuba a portion was not available for service at the time it was most needed, to wit: on July 1, 2 and 3, when the wounded from El Caney and San Juan were coming from the front for care and treatment. This was because, in general, no opportunity was afforded to land the medical property. Earnest efforts were made by medical officers to have supplies at the front with troops. Some having succeeded in getting their medicine chests and other articles of medical property ashore, had these carried forward on litters by hospital corps men to the camps near Sevilla, while others turned their private mounts into pack-horses for this purpose. During and after the battle at El Caney and San Juan there was an insufficiency of tents, cots, bedding

and medicines due to the causes stated, but all the hospitals were well equipped for surgical work.

After the capitulation of Santiago, the troops at the front broke down rapidly under the fatigues they had undergone and the malarial influences to which they were exposed; but by this time an ample supply of tents, furniture, bedding, clothing and medical stores had reached Siboney, together with a corps of trained nurses and a force of surgeons, those sent to duty at the yellow fever hospital being immune to that disease. Meanwhile, to relieve the pressure on the field hospitals, such convalescents and sick as could bear the journey home were sent to the United States on transport vessels. This was an emergency measure to relieve the hospitals at Siboney and permit of the transfer to them of the men who were sick in regimental camps.

The transfer of troops from Santiago to Montauk Point was also an emergency measure, and the great responsibility of excluding yellow fever infection from every transport rested on the medical officers who had charge of the embarkation. Had they failed in this duty the effect would have been disastrous during the voyage to the men confined on shipboard, and the risk of importing the disease into this country would have been greatly increased.

In view of the necessity for the return of the troops of the Fifth Army Corps from Santiago, Cuba, preparations were made for encamping them at Montauk Point, Long Island. These included the establishment of temporary tent hospitals, not only for the treatment of the large number of sick brought by each command from Cuba, but for the isolation and treatment of those from transports lying under the suspicion of yellow fever infection.

The difficulties in the way of administering the affairs of the detention hospital were very great, owing to the rapidity with which the transports followed each other in their arrival. As many as four reached the Point on some days from August 13 to 31, most of them bringing sick requiring detention for medical observation; but the sick men were as well cared for and as comfortable in their cots here as afterward, when transferred to the general hospital at Montauk Point. There was an excellent steam disinfecting plant with a formaldehyde chamber attached. The laundry work was done at a steam laundry near the hospital.

The temporary hospital, which was locally known as the general hospital, Montauk Point, consisted of tent pavilions containing 1672 cots. Its personnel consisted of 40 medical men, 8 stewards, 10 acting stewards, 130 privates of the hospital corps, 15 cooks, and 50 male nurses and an average of 200 female nurses, one half of whom were Sisters of Charity. Supplies of all kinds were amply provided.

It is needless to refer at this time to the complaints of starvation which appeared almost daily in the newspapers during the occupation of Camp Wikoff, for it is now generally understood that the weakness, prostration, anemia and emaciation of so many of the troops were the results of malarial, typhoid, and yellow fever, from which the Army suffered as a consequence of its exposure to the climatic influences and local infections of Santiago and its neighborhood, pending and subsequent to the surrender of the city.

TROOPS IN THE HOME CAMPS.

The method of hospital organization in these camps was practically the same; and there was much similarity in the conditions affecting them and correspondingly in their history. Regiments reported in but few instances with the material and supplies for their medical care; but they brought sick men with them and these required immediate care. Provision had to be made for division hospitals in view of the immediate necessity. The difficulties in the way of the contemporaneous accomplishment of these two objects were great, and they were greatly augmented by the inexperience of a majority of the regimental medical officers and of many of the chief surgeons, which prevented them from seeing beyond the immediate necessity. The sick had to be cared for, and to this end medicines and other things had to be procured. Relief societies offered assistance, and this was eagerly accepted by many of these medical officers, not alone for delicacies or luxuries not otherwise provided for, but for supply table articles which could have been had from the medical purveyors in their camps, or by telegraphic requisition on the Surgeon-General. It was easier to accept what was so freely offered than to learn how to obtain the articles from the proper source. To explain their prompt acceptance of this assistance these officers referred to the red tape of the War Department methods, and the insinuation that the said methods were beyond the comprehension of the ordinary intellect was accepted by the sensational press as an explanation in full.

Meanwhile, chief surgeons of corps and divisions began the organization and equipment of their field division hospitals and ambulance companies, but they were met at the outset by the apparent impossibility of securing men for service as cooks, nurses, litter bearers, ambulance drivers, teamsters, etc. The hospital corps of the regular Army could not supply these men, because recruiting for this corps progressed slowly. The popular tendency to volunteer led men away from the regular recruiting offices. When teamsters from the volunteer regiments to the regular hospital corps were authorized, the men did not care to leave their local connections for service in the Army at large, as regular soldiers. The transfers so much desired by the medical department to enable its organization were not regarded favorably by line officers, for although every line officer will probably acknowledge as a general principle that only the most intelligent and capable men should be employed to care for the sick and wounded, he is not likely to act on this general principle when it is a question of withdrawing for such service the most intelligent and capable men of his own company or regiment.

The division hospitals of the army corps were usually established in the immediate neighborhood of the regimental camps of the divisions. The pavilions were arranged in various ways according to the configuration of the area available as a site; but in general there was a tendency to crowd the area. Surgeons in charge recognized that a tent should not be occupied by more than six patients, but sometimes this number was exceeded temporarily while waiting an increase of tentage. As a rule, the hospitals were kept in campaigning condition, that is, the tents were neither framed nor floored, until the increased prevalence of typhoid fever attracted attention to their crowded condition, when the object of their existence became suddenly changed from a school for field service to a hospital for the treatment of a local outbreak of disease.

Special diet kitchens, under the management of capable individuals, were opened at most of the hospitals. Money for this purpose was sent to them by me from funds contributed and placed at my disposal. Money was also sent directly by individuals and representatives of aid societies; and the Red Cross committees supplied ice and milk, chicken, eggs, lemons, etc. Pajamas, night shirts and other articles of hospital clothing were also provided by the Red Cross and other aid societies. Subsequently the order authorizing the commutation of the sick soldiers' ration at 60 cents rendered these hospitals wholly independent of outside assistance.

About July 20 the troops for the invasion of Porto Rico embarked and sailed. The field hospital accommodation with this expeditionary force was ample and the supplies abundant.

TROOPS ON THE PACIFIC COAST.

The troops on the Pacific Coast were concentrated mostly at San Francisco, Cal. Eighteen thousand troops were dispatched to the Philippine Islands. They were carried on twenty transport steamers, the first expedition sailing May 25. Each steamship, before being accepted by the government, was inspected by a board of medical officers, and in each instance the vessel was thoroughly disinfected before the troops went on board. The precautions taken to secure a good sanitary condition of the vessels prior to embarkation and the sanitary supervision exercised over the men during their long voyage must be credited with the excellent condition in which the troops arrived at Manila.

The want of hospital-corps men was the main cause of the failure of chief surgeons to establish their division hospitals promptly. Instead of organizing for field service, their time was occupied and their energies spent in endeavoring to procure the necessary men by enlistment or transfer. After a time, when sickness invaded the camps and the division hospitals became filled, operations for field service had to give place to the immediate necessity of caring for the sick. The division hospitals became expanded, as at Siboney and Tampa, into base hospitals with increased needs and increased responsibilities. To these I sent with the utmost dispatch physicians and surgeons under contract, to relieve the details from the regiments who were temporarily acting as hospital-corps men. At Camp George H. Thomas, Ga., the expansions of the division hospitals, under the conditions brought about by the typhoid invasion of the camps, became officially recognized as general hospitals and were promptly provided by me with the best available medical service, with trained nurses, with all permissible medical and hospital supplies and with funds for special purchases. The altered conditions under which the division hospitals were operating were immediately recognized by the chief surgeon of the Fifth Army Corps at Santiago, on the break down of that corps after the surrender of the city, and every effort on the part of his medical officers to care for their sick in

regimental hospitals was encouraged by giving them every available facility. Similarly, in other camps, regimental hospitals were in many instances equipped to meet the necessities of the occasion.

GENERAL HOSPITALS.

Up to September 30, eleven general hospitals were established and fully manned and equipped. These had a capacity of nearly 7000 beds. At the same time certain post hospitals having good accommodations were used for the treatment of army cases generally, without alteration of their official status as post hospitals. Those, for instance, at Forts Columbus, Hamilton and Wadsworth, N. Y., and Vancouver Barracks, Wash., on the Pacific coast, were expanded in this manner. The vacant beds in the hospitals of the marine-hospital service of the Treasury Department were placed at my disposal and the civil hospitals of the country were ready on call to receive and care for the sick and wounded soldiers. These offers of hospital accommodations and medical care were accepted by me in many instances, particularly in New York, Boston, Philadelphia and Providence, to relieve the tent hospitals at Montauk Point, when crowded by the rapid transfer of sick from Santiago.

THE MEDICAL STATISTICS OF THE WAR.

The work of gathering up the records of sickness of the various commands in service during the war has been one of great difficulty. Volunteer medical officers were ignorant of the methods of keeping the records, and many failed to appreciate the importance of what was frequently regarded as "mere paper work," which had no practical bearing on the welfare of their men. Nevertheless their work in this regard must be considered as satisfactory when compared with that of the volunteer medical officers of the War of the Rebellion.

My report presents tabulations compiled from monthly reports of sick and wounded received from May to September, inclusive, and representing a strength present of 167,168 men. These give full particulars of 1715 deaths, of which number 640 were occasioned by typhoid fever; 97 by malarial fevers and 393 by diarrhea and dysentery. The death rates for May and June—46 and .70—were not in excess of those of the Army in time of peace. In July the rate became somewhat higher than that of an annual rate of 25.80 per thousand living. In August it became excessive, 4.08 for the month, equal to an annual rate of 48.96 per thousand. In September, the influence of the energetic measures taken, in July and August, to improve the health of the Army becomes manifest in the falling of the death-rate to 2.45, or the equivalent of an annual rate of 29.40. The same progression to an acme in August, with a sudden fall in September, is seen in the various ratios given under the specific titles, typhoid fever, malarial fever, and diarrheal diseases. This is exceedingly gratifying and must be credited, as stated, to the sanitary measures adopted, for our experience in the Civil War demonstrates that in the absence of these measures the high ratio of August would have been continued for many months to come.

I submit also tables of absolute numbers and of ratios by which the incidence of sickness and mortality of the regular and volunteer troops may be contrasted. From these it will be seen that the exposures of the regular troops during the Santiago campaign gave them from June to September a higher death-rate than the volunteers, and that the rate of the latter during August, the month of maximum mortality, was 3.62 as compared with 5.83 among the regular troops.

VOLUNTEER RELIEF WORK.

My guiding principle through out the war has been that relief when needed should be promptly accepted without reference to the source from which it came. The relief afforded by the National Red Cross at Siboney was promptly accepted by the surgeons on the spot, but it is evident that it was entirely inadequate to meet the emergency. This association has had full authority to send agents and supplies to all of our camps since June 9, 1898, and it has contributed supplies of various kinds in a most liberal manner for the use of our field hospitals. Other organizations which have rendered very valuable services are the National Relief Commission, having its headquarters in Philadelphia, and the Massachusetts Volunteer Aid Association, with headquarters in Boston. Both these organizations fitted out hospital ships, which were placed at my service for the transportation of our sick from Porto Rico, and I take pleasure in testifying to the valuable services rendered by the yacht *May*, of the National Relief Commission, and the hospital ship *Bay State*, of the Massachusetts Volunteer Association.

¹ Reports to the Adjutant-General to Sept. 30, 1898, show 345 killed and died of wounds and 2485 died of disease in a mean strength of about 275,000 men.

SPECIAL FUND.

Sums of money varying from 33 cents, sent by Master Oliver S. Whittaker of Detroit, Mich., to \$5000, by Mr. Cleveland H. Dodge, chairman of the Supply Committee, National Red Cross Society, have been sent to me to be used according to my discretion for the benefit of our sick and wounded soldiers. In all I have received \$21,214.94. Among the contributors have been: The Colonial Dames of America, through the treasurer, Miss E. B. Nicholas of Washington, D. C., \$3500; The Red Cross Auxiliary, No. 3, through Mrs. Winthrop Cowdin of New York, \$2000, and the Woman's War Relief Association, through Mrs. Victoria Raymond, treasurer (contributed for Hospital Ship Relief,) \$2275. This money has been sent principally to general hospitals, to chief surgeons of army corps in the field, and to commanding officers of hospital ships, to be used in the purchase of delicacies for the sick.

THE MEDICAL CORPS.

Before concluding my report of the operations of the medical department during our short and glorious war with Spain, I feel it my duty to call special attention to the efficient services rendered by the medical officers of the Army in the various responsible positions which the exigencies of the service have made it necessary for them to fill. The inadequacy in the number of trained and experienced medical officers has been a source of great embarrassment to me in my efforts to meet the demands of the service; but as a rule our medical officers have performed the duties imposed upon them in a most loyal, intelligent and zealous manner. They have shared with line officers the dangers of battle, and they have encountered with unflinching courage the more difficult and protracted combat with the infectious diseases which have invaded our camps and filled our hospitals. Many of them have suffered attacks of typhoid and malarial fevers and at one time no less than 15 per cent. of the corps was disabled by sickness. Of those who accompanied General Shafter's army to Santiago, few escaped serious sickness and two of those who distinguished themselves for their devotion to duty lost their lives as a result of exposure to the malign influences which in so short a time sapped the vitality of the flower of the American Army. Credit is due not alone to those in the field. The labors of those on duty as chief surgeons of military departments, in charge of medical supply depots and in other important positions have been enormously increased and it has required unremitting effort to meet the exigencies of the war.

RECOMMENDATIONS.

The increase of the enlisted strength of the Army to a total of 60,000, and the large number of new stations to be garrisoned in the islands acquired and occupied by the United States, makes an increase in the medical corps absolutely essential. I therefore recommend an addition to the number of medical officers now allowed by law, of two assistant surgeons general, with the rank of colonel, six deputy surgeons general, with the rank of lieutenant-colonel, thirty surgeons with the rank of major, and fifty assistant surgeons with the rank of first lieutenant. This recommendation is based upon the present organization of the Army. Any increase made by Congress during the coming session will necessitate a further increase of the medical corps.

Very respectfully,

(Signed)

GEO. M. STERNBERG,
Surgeon-General, U. S. A.

SOCIETY PROCEEDINGS.

The British Sanitary Institute.

Seventeenth Congress.

The seventeenth congress of the Sanitary Institute was opened at Birmingham, Eng., September 2, last. About 1500 members were present, including most of the leading lights of sanitary science and many of those engaged in the actual administration of sanitary laws, as medical officers of health, municipal engineers, sanitary inspectors, etc.

The LORD MAYOR delivered the address of welcome to the Institute.

Sir DOUGLAS GALTON, responded, and in the course of his remarks, lamented the action taken by the Government in relaxing the laws relating to vaccination. He was not one of those who held that these laws could not be relaxed but he believed they could not be relaxed under the conditions which the Government had sanctioned. They could be relaxed were

the Leicester system of isolation introduced everywhere, but without that safeguard it was absolutely wrong to have made any change.

Sir JOSEPH FAYRER delivered the presidential address, in which he reviewed the progress of sanitary science and of the Institute. He pointed out the improvement in the vital statistics of the people as shown by the reduced death rate, the enhanced expectation of life, the decline in some of the most potential causes of death and the almost total disappearance of others. The Institute had taken an important part in effecting these improvements. Its object from the outset had been the advancement of sanitary science by the promulgation of sound scientific and practical teaching of those principles on which health depended, by which life was prolonged and the physical, and thereby the moral welfare of the people promoted. It was only comparatively recently that preventive as distinguished from curative medicine had assumed the position of a science; but it was now, from a hygienic point of view, the more important of the two, although the difficulties attending its application were still considerable and largely such as arose from ignorance and incredulity. Half a century ago the great mass of the population lived and died under conditions which violated all the now well known principles on which health depended. Measures which were then regarded as mere facts or theories of no practical value were now accepted as of cardinal importance. Statesmen had learnt to realize that sanitary science came well within the domain of practical politics, and that it was an important part of the duty of executive governments to protect the people from disease which might be prevented or controlled. Acts of Parliament, officers of health and sanitary inspectors had produced a better state of things and the poor were no longer left to be a law unto themselves. When the present state of the country with its thirty one million people was contrasted with that of the Elizabethan era with its four millions, there was ample proof of the ignorance of science in those days and of the great improvements which have taken place in these. Many of the diseases of that time had disappeared and others had been mitigated; but sudden invasions of cholera and other epidemics, even of bubonic plague, gave evidence that vigilance must never be relaxed.

The health exhibit was formally opened in the evening. The Institute all through its history has encouraged improvements in sanitary appliances by having an exhibit in competition, but the main objects of the exhibit are to educate the general public and to disseminate a knowledge of how best to effect sanitary improvements.

On the second day of the meeting the work of the Institute was divided into five conferences or sections.

In the first, or that of municipal representatives, the conditions of Birmingham were especially discussed, and papers were read on the dwellings of the laboring classes and on the desirability of having public abattoirs instead of private slaughter-houses.

In the Section of Medical Officers of Health the chairman's address counseled a cheerful acceptance of the law temporarily abolishing compulsory vaccination. If all artificial pressure were abolished there would still remain the strongest natural pressure toward vaccination in smallpox itself. To prevent the people from paying too dearly for their education by means of smallpox epidemics, medical officers of health were urged to do all in their power to promote the acceptance of vaccinal protection. One paper discussed the bacteriologic and clinical diagnosis of diphtheria, claiming that neither method was conclusive by itself, but that the two together enabled a correct opinion to be formed in the majority of doubtful cases. A paper on hospital reform condemned the practice of congregating large numbers of patients in hospital waiting-rooms as being calculated to spread disease while the medical staff were unable to give them prompt attention.

The Section of Municipal and County Engineers devoted most of its time to dwellings for the working classes. A paper on the ventilation of sewers had nothing new in its recommendation that shafts should be fixed to the tallest buildings, high factories and churches being utilized for this purpose. Another paper somewhat in advance of the times urged the sanitary advantages of motor vehicles over horse drawn vehicles.

In the Section of Sanitary Inspectors a good deal of discussion was raised by a paper which threw doubt on the practical qualifications of those certified by the Institute for appointment as inspectors. The author advocated examination by a council of prominent representatives of the profession.

The Section of Domestic Hygiene was presided over by the Lady Mayoress, who congratulated the women on having been invited to take part in such a congress. It was a sign of the progress of the times, and indicated an appreciation of the public work which women were now doing. She advocated the

election of women as guardians, factory inspectors and sanitary inspectors. The papers read were on the influence of women in household sanitation, or district nursing, its aims and methods; on the need of sanitary knowledge for nurses; on the claims of childhood and on the hygiene of dress.

Dr. ALFRED HILL on the third day delivered an address on food preservatives, in which he discussed methods for effecting preservation as by drying, smoking, salting, the use of sugar and vinegar, the exclusion of air, mineral or organic antiseptics and cold. He concluded that the use of chemic preservatives ought to be condemned altogether because they were harmful in large doses and the quantities added by food manufacturers were uncertain. Besides, their use could be supplanted by refrigeration. During the past year no less than 6,551,280 cwt. of meat had been imported from Australia, the Argentine Republic and the United States of America without the employment of any other means than refrigeration or freezing, the latter method having been employed for the meat sent from the two former countries and the chilling or refrigeration only for that from the United States.

Dr. CHRISTOPHER CHILDS delivered the most important of the addresses of the session, on the prevention of the pollution of river and streams. He instanced various reforms that were necessary and expressed a hope that all concerned in the health and welfare of the nation would urge upon Parliament the necessity of the Rivers Pollution and Prevention Bill.

On the fourth day a large number of papers were presented at the gathering.

Dr. H. SCURFIELD of Sunderland contributed, "Suggestions for the Improvement of the Milk Supply." He considered the Somerset House standard too low. It was, in his opinion, unreasonable to fix upon such a low standard because an occasional cow gave milk of this character. The fat standard should be raised to 3.25 per cent. He suggested that local authorities should draw up model regulations and issue certificates to farmers who complied with them.

Mr. JAMES MANSBERGH presented the paper of the day, however, on the Birmingham water scheme of bringing water to the city from the mountains of Wales. He described the work of damming up the water courses so as to transform the mountain valleys into lakes or storage basins which would hold sufficient for a dry period of nearly half a year. Tunnelling for thirty miles is involved in this scheme.

Professor FRANKLAND opposed the ideas advanced in several papers on the bacteriologic method of disposing of sewage. He said that in his opinion, there was nothing which could surpass the results obtained by intermittent downward filtration and irrigation.

On the social side the Institute was entertained at several lunches and receptions and was treated to excursions to Dudley Castle, the Waterworks and the sewage farms.

Chicago Academy of Medicine.

Meeting of Nov. 21, 1898.

Dr. A. LAGORIO occupied the chair.

Dr. FRANK X. WALLS presented a paper to the meeting on
DIAGNOSIS OF CHRONIC DIFFUSE PERITONITIS.

Chronic diffuse peritonitis from a clinical point of view was classified as simple, tubercular or neoplastic, not considering other infrequent varieties such as, for instance, echinococcus peritonitis, etc. Chronic general peritonitis usually attended with exudation, and in direct proportion to the exudation is the diagnosis involved. The essayist said that much discussion has arisen as to the existence of a simple, non-tubercular, exudative peritonitis, though cases have been described as occurring more frequently in children, by Strumpell, Henoch, Baginsky, Filatoff and others. A priori, there is no reason why we should deny a chronic simple inflammation to the peritoneum, even though we admit the condition to be infrequent. The disease develops insidiously, often after a history of trauma or exposure. Pain and abdominal distension are the most prominent symptoms, attracting attention to the peritoneum. The pain is seldom excessive, arises spontaneously, or is elicited on palpation of the abdomen. The pain is usually diffused over the abdomen, or regions of excessive tenderness may be complained of or revealed on examination. Fluid effusion is usually present, though the quantity varies within very wide limits. The field is usually free, but it may be encapsulated, and if examined after aspiration, reveals the characteristics of an exudate. The most characteristic differences as contrasted with ascitic fluid of non-inflammatory origin, are specific gravity above 1016, albumin in considerable quantity and an abundant sediment rich in granular leucocytes. Moderate

elevation of temperature is often present at the onset, but later the disease usually pursues an afebrile course. Other general symptoms may be present, more especially intestinal, cardiac, renal or nervous, and vary much in their kind and degree.

The differential diagnosis should exclude tubercular or cancerous peritonitis and ascites. Osler and Baginsky have reported each a case of chronic peritonitis, in which tubercle bacilli were demonstrated in the lesions during the early stages of the disease, but later, when the cases came to autopsy, careful search for bacilli or characteristic tubercular processes by competent pathologists was negative. The deduction is warranted that the absence of bacilli or tubercles in a chronic peritonitis is no indication that the morbid condition was not initiated by the bacillus of tuberculosis, and also that autopsic negative findings are quite consistent with a previous tubercular infection.

There is no characteristic picture of chronic tubercular peritonitis. At times the diagnosis is evident, while in other cases a laparotomy or postmortem reveals the presence of a tubercular peritonitis that previously had not been suspected or had been excluded. Tubercular peritonitis may arise insidiously from a latent pulmonary tuberculosis, from a caseous mesenteric or bronchial lymph gland, from an intestinal tubercular ulcer, from a hidden focus in the urogenital apparatus, more especially the testis or Fallopian tube, or from a bone or joint affection. In every case exhaustive examination for a primary focus must be instituted, and its presence or absence is of considerable weight in diagnosis, as tuberculosis of the peritoneum is rarely, if ever, primary. The usual symptoms that draw our thoughts to the peritoneum are pain, distension of the abdomen and symptoms of gastro-intestinal derangement. The pain varies much in its character, constancy and intensity: Usually dull, it may be sharp; frequently intermittent, it may be continuous; as a rule, mild, it is rarely intense. Some tenderness is generally provoked on palpating the abdomen. Vomiting, diarrhea and meteorism are frequently present, though often mild. Palpation or auscultation might elicit peritoneal rub or friction. The inflammatory effusion may be free or encapsulated; it may give rise to physical signs of isolated neoplasms in the peritoneal cavity. The palpation of the curled up omentum has a hard, firm, elongated sausage like body, lying transversely in the epigastric region, is hardly sufficient to correct such an impression, as it is also present in carcinomatous peritonitis, though more frequent in tubercular. Sometimes the omentum is to be palpated only after evacuation of the exudate, and, instead of being in the epigastric region, it may form a prominent tumor in the right iliac region (Osler). When the effused fluid is free in the peritoneal cavity, the relation of the dullness due to the fluid and the tympany of the bowel, as elicited by percussion, gives rise to a sign described by Thomayer. This sign is a very important aid in the diagnosis of chronic peritonitis. In such cases, with the patient in the dorsal condition, we do not find the area of dullness symmetric on both sides of the abdomen with tympany in the median line, as we find in non-inflammatory ascites; but we notice that the dullness is much more extensive on the left side, and the tympanic area greater on the right side. Thomayer reports eight cases of chronic peritonitis—five tubercular, three cancerous—in which this sign was present, and was of great value in the diagnosis. The essayist reported a case illustrating the sign of Thomayer.

The symptomatology of cancerous peritonitis is very similar to that of chronic peritonitis, and the diagnosis is to be made, as a rule, after determining a primary carcinoma. When the primary tumor is evident, these cases present no difficulty in diagnosis, but when the cancerous peritonitis develops upon a latent cancer of the stomach, bowel or ovary, the diagnosis may be extremely difficult. In every case careful examination of the stomach (physical examination and chemic analysis of the stomach contents), as well as digital exploration of the genital organs and the rectum is to be made. The age, cachexia, determination of multiple tumors in the abdomen, in addition to the other evidences of peritonitis, are the usual criteria of chronic cancerous peritonitis. Chronic peritonitis, simple, tubercular or cancerous, clinically might be simulated by a greatly dilated stomach (Leube) or distended urinary gall-bladder, but in a given case could easily be excluded by aid of a stomach-tube or catheter. Ascites (hydro-peritoneal) and ovarian cyst, perhaps more often than any other conditions, are to be considered in the differential diagnosis, and the not infrequent association of chronic peritonitis with cirrhosis of the liver is to be borne in mind.

Dr. REUBEN PETERSON—I have been much interested in Dr. Walls' paper, because, in my experience, chronic peritonitis is a disease that it is exceedingly difficult to diagnose, especially the tubercular form. I am unfamiliar with the simple chronic per-

itonitis; I have never diagnosed a case, but in quite a number of instances I have made a diagnosis of tubercular peritonitis after I had opened the abdomen. Tubercular peritonitis is of special interest to the gynecologist. The starting point in many cases is from the tube and ovary, yet before operation these organs do not give evidence of a tubercular lesion. We have adhesions and make a diagnosis of chronic salpingitis and ovaritis, and upon operation we find the peritoneum studded with tubercular masses. Williams of Johns Hopkins and Edebohl of New York have written valuable papers on cases of unsuspected tuberculosis. Specimens taken from the appendages, not considered to be tubercular, which have been subjected to microscopic examination reveal them to be of that nature. I was particularly interested in the paper because some few years ago I had a number of cases of tuberculosis of the mesenteric glands. I had three cases, two being in the same family, sisters, and the diagnosis in the first case was made after the abdomen was opened. I found the mesenteric glands enlarged and no other disease present. I operated on the sister, not because I could feel the enlarged mesenteric glands, but because her symptoms were so similar to the first case. I had one other case, the treatment of which simply consisted in opening the peritoneal cavity and draining. That was about two and a half years ago, and the patients have remained well up to this time. Acute tubercular peritonitis is very liable to result from trouble with the mesenteric glands, and this disease, when limited to the glands, is so difficult of diagnosis that it makes it particularly interesting. These three cases had indefinite pains and other symptoms referable to the abdomen, and it would seem that, given a case of somewhat long standing abdominal pain, it would be well for the surgeon to bear in mind that it may be due to a tubercular affection of the mesenteric glands. The Doctor has not gone into the treatment of chronic tubercular peritonitis, hence it can not be brought up in the discussion.

Dr. JAMES G. KIERNAN—I would like to ask Dr. Walls whether he considers ascites in the nature of a true peritonitis.

Dr. WALLS—No. In the conditions in which I have used the word "ascites," I wish it to be understood as a non-inflammatory condition, the ascites representing merely an accumulation of fluid because of some probable circulatory or vascular disturbance: in other words, a dropsy of the peritoneal cavity, depending upon hepatic or portal vein disease either primary or secondary to the heart, or occasionally, as may occur, in renal disease from possibly a hydremic condition of the blood plus increased vascular permeability.

Dr. KIERNAN—You use the word, then, only in the sense of a hydroperitoneum?

Dr. WALLS—Yes, sir.

Dr. CHARLES S. BACON—I would like Dr. Walls to state the manner in which he uses the term simple peritonitis. The use of the term is quite important from a diagnostic standpoint. All of the inflammations of the peritoneum which arise from various sources, such as ulcers of the intestines, inflammation of the pancreas, the liver or gall duct, etc., are very important. They may be chronic in their course and hard to differentiate from tubercular peritonitis. In this connection I wish to relate briefly a case which gave me considerable difficulty in diagnosis and has a direct bearing upon the subject. A woman had long been sick and came of a tubercular family. She had nursed different members of the family who had had tuberculosis. She had a low chronic peritonitis with an abscess of the abdominal wall which naturally would lead us to suspect a tubercular peritonitis. But upon examining the contents of the abdominal abscess as well as the peritoneal exudate, there were no tubercular bacilli. There were, however, stones in the gall-bladder which had first caused a pericholecystitis and later an invasion and infection of the abdominal wall and peritoneum with the colon bacillus. This case has an important bearing upon the diagnosis, and these are practically the cases we have to deal with in the differentiation.

Dr. FREDERICK S. COOLIDGE—I do not feel that we should leave this subject in its present status, and I hope further discussion will bring out some points of interest regarding the pathology of this disease. In the first place, as far as my own experience goes, Dr. Walls has stated that cancerous peritonitis occurs only in the old, whereas tubercular peritonitis occurs in the young. I have seen a good many cases of tuberculosis of the bones and joints in young children, and I must say it is extremely rare to find tubercular peritonitis occurring in these cases. There are a few cases of tuberculosis of the retroperitoneal glands, from which tubercular peritonitis might arise, the involvement of these glands being secondary to the bone or joint tuberculosis, but the condition must be extremely rare. Dr. Walls, in speaking of the diagnosis, said that in tubercular peritonitis the spleen is not enlarged as a rule, but in one

or two cases of tubercular peritonitis, as shown later by autopsy, there was enlargement of the spleen from amyloid degeneration, which occurred not only in the liver, bowels and kidneys, but also in the spleen. I should like Dr. Walls to say something in his closing remarks as to the pathology of the disease before we leave the subject, and also, if he has any explanation why simple paracentesis or opening the abdomen produces a cure in many cases. We were taught years ago that tubercular peritonitis was absolutely fatal; later, when the abdomen was opened and peritonitis was diagnosed, some of the cases got well. Whether the opening of the abdomen is simply a coincidence in these cases, as far as a cure is concerned, I do not know. I do not feel that the subject will have been complete until we hear from the essayist a little more fully.

Dr. WALLS (closing the discussion)—In presenting this subject to the Academy, I stated that I should deal with the differential diagnosis and consider more especially the common varieties of the chronic exudative peritonitis. I specifically stated that I should not deal with the more unusual varieties, such as echinococcus, actinomycosis, and possibly glanders, because it would prolong the discussion. The differential diagnosis of peritonitis from such conditions as pancreatic cysts, hydrops of the gall bladder, or even appendicitis, might possibly be considered clinically, but those cases would be unusual. In cysts of the pancreas, if we consider that phase of the subject, some attempt should be made to examine the digestion of the fats or look for the presence of sugar in the urine, which might be of some aid. But I did not consider the unusual forms of peritonitis, but the commoner forms of the disease. I wished to discuss more in detail the symptom reported by Thomayer, which is an important one, and which apparently has been either overlooked or has not met with favor in the hands of physicians. Indeed, it is hardly mentioned in the literature of the subject. Peritonitis following perforation is usually discussed with acute peritonitis. The disease may extend over a considerable length of time, and the symptoms would be of an acute rather than of a chronic peritonitis. In answer to Dr. Bacon's question as to the definition of simple peritonitis, I can not say any more than I have said, namely, that this name is given to the varieties of peritonitis that occur after a history of injury, sometimes exposure, or some have even considered a rheumatic tendency, in which the peritonitis develops more or less insidiously, rather slowly, and evidences of tuberculosis are absent. Some authors consider that many of those cases are really tubercular, and you will remember that reference was made to a case described by Osler and Baginsky, in which, during the course of the disease, a small portion of peritoneum was removed, carefully examined, and tubercle bacilli were found. The cases continued under observation for some time, and later died from some cachectic condition that developed. The findings were that all evidences of tuberculosis had disappeared; nothing was found that looked like a tubercular product. Cases of tubercular peritonitis may become simple. There is no good reason why we may not have a non-tubercular inflammation of the peritoneum. Possibly there is some variety of bacteria or toxic product that might bring about so called simple peritonitis. Why a case of chronic tubercular peritonitis recovers after operation, I can not answer from a pathologic point of view, other than to suggest that in a general way it may be due to some vascular disturbance, or the removal of pressure, or to the action of the atmospheric air upon the peritoneum. It is difficult to give a satisfactory answer as to why these cases are cured. It seems to be a fact, however, that a greater number of cases of tuberculosis recover after operation than recover without operation.

Dr. COOLIDGE—Will you kindly tell us, Dr. Walls, a little more about the pathology of peritonitis.

Dr. WALLS—The pathology of tubercular peritonitis is the same as that of tuberculosis in general. It depends upon the entrance of the tubercle bacilli by means of the blood channels, lymphatics, etc., and the reactionary product varies in different cases, probably depending upon the number and virulence of the micro organism, resistance of the individual, etc. Too much time would be consumed in a detailed discussion of the pathology of chronic tubercular peritonitis, and in my paper I confined my remarks to the diagnosis.

Dr. L. LOEB read a paper on

THE TRANSPLANTATION OF THE SKIN AND THE ORIGIN OF THE PIGMENT OF THE SKIN.

Experiments were made on the ears of guinea-pigs. White skin was put on a wound in black skin and black skin on a wound in white skin. The results were as follows:

1. Black skin adhered and remained permanently. White skin did not adhere for any length of time, the longest period

of time being four and one half weeks. So we learn of an unexpected factor in transplantation. The different structure of the white and black epithelium of the guinea-pig seems to cause the different result in transplantation.

2. These experiments show that the transplanted white skin is often thrown off after the union with the underlying tissue has become complete and microscopically absolutely normal, and although in the deepest layers the number of mitoses is increased and at the edges of the piece of skin regeneration takes place. So we learn of a secondary disconnection of transplanted skin after it has grown fast and lived for some time.

3. Transplanted black epithelial cells migrate into the neighboring white epithelium, and, if white epithelium is transplanted, the neighboring black epithelial cells infiltrate the white epithelium. In this way the black skin substituted white skin. Microscopically, no signs of degeneration of the neighboring white cells can be seen. Therefore, under these conditions, apparently normal white epithelium is infiltrated and substituted by cells of the black epithelium.

These experiments, in connection with a number of other experiments and observations, prove also that the pigment of the black skin is not carried into the epithelium through cells from the connective tissue, but that it has its origin in the metabolic changes of the epithelial cells alone. This is proven by the following facts:

1. The transplanted black epithelium remained in almost all cases permanently black, and the transplanted white skin remained white as long as it adhered. Therefore, both white and pigmented epithelial cells can live, each on the tissue of the other, and yet one kind of cells will produce pigment, the other not. This shows that the nourishment which the epithelium received from the tissues upon which it is grafted does not influence the production or non-production of pigment in the epithelium. So far it is entirely unknown what food the epithelial cells require to produce pigment. Nothing proves that it must be hemoglobin. But this we know, that the main factor for the production of pigment lies in the structure of the epithelium which must be different in white and black skin. (In these experiments epithelium without any connective tissue, or with only an occasional thin layer, on which no sign of regeneration could be seen, was transplanted.)

2. We can induce black epithelium to regenerate over white connective tissue, and yet the regenerated epithelium remains permanently pigmented.

3. The originally unpigmented cutis on which black epithelium has been transplanted, or on which black epithelium has regenerated, became afterward pigmented, particularly the cells resembling chromatophores appearing only secondarily in the cutis.

4. The study of the regeneration of the black epithelium leads to the same conclusion. The pigmentation in the regenerating black epithelium takes place in a remarkably regular way. Never was the pigment carried from the connective tissue into the epithelium. There is a stage in the pigmentation, when ameboid-like chromatophores appear at the base of the epithelium, no such chromatophores having previously appeared in the cutis.

5. To the regenerating black epithelium the chromatophores behave like the basal epithelial cells. They show mitotic division just at the same places and at the same time as the ordinary basal epithelial cells show an increased number of mitoses. No such mitoses can be seen in the cutis.

6. If we observe the localization of the pigment in the normal black epithelium, we find facts which are very easily explained by this theory, but which would be hard to explain by the supposition that the pigments carried from the connective tissue into the epithelium. The hair glands of the guinea-pig were found always free from pigment. A decrease of the pigment takes place in the upper layers of the epithelium, where the Malpighian layer changes into the granular and horny layers. Chemic processes in the Malpighian layers lead to the formation of pigment. Chemic processes apparently lead to the destruction of the pigment, particularly in those places where new chemic substances arise in the skin, such as eleidia and keralin; that is to say, where chemic transformation takes place. In the hair glands of the guinea pig the chemic processes probably differ from those in the epithelial cells; in these glands, correspondingly, no pigment is produced. That seems to be the most probable explanation. The peculiar distribution of the pigment granules in the normal as well as in the regenerating black epithelium (showing a polarity of the cells) points to the same conclusion.

Dr. WILLIAM L. BAUM—The work of Dr. Loeb is decidedly original in its character. I was exceedingly interested in the paper, for the reason that it corroborates to a great extent

clinical experience in regard to the skin in colored individuals: that is, there are evidently qualities preëxistent in the skin of colored individuals different from those in whites. We find this to be true in the greater number of diseases characterized by rapid exfoliation of epidermal cells; they are never so marked in the colored races as in the white. It is also not of the same character as in the white skin. One fact, which has always been of considerable interest to me, and which is explained by these investigations, is that in the colored races the skin pigmentation recovers after stimulation in scar tissue where the scar itself has been devoid for a long period of time of pigmentation. The reason why there could not be this skin pigmented condition present in the follicles of the skin is explained by Dr. Loeb's work. The follicles are after all lined by the stratum granulosum, which, according to his investigations, does not contain epithelial cells, and therefore does not in the beginning have the same chemic conditions present. The pigmentation of skin has been a bone of contention among dermatologists for many years, and no satisfactory conclusion has been reached as to the origin of the pigment. The Doctor's explanation is not only an ingenious one, but is borne out by the results of his own investigations.

Dr. W. X. SUNDUTH—This paper is one of great interest from an embryologic standpoint, although that phase of the question was not dwelt upon to any great extent. It seems to me, that the experiments the Doctor has carried on admirably demonstrate the truth of the old theory of the individuality of cell life; and another point, that pigmentation is a local and transitory condition rather than a permanent one. We know the skin is divided into two layers, the epidermis and the cutis vera, and these two layers arise from two separate layers of the blastoderm, the external and middle layer, and the cells in these two separate layers have separate characteristics. The epidermis has three distinct layers, the stratum Malpighii, stratum granulosum, and stratum corneum. The two outer layers are older stages of development of the stratum Malpighii which is the deeper or infant layer of the epidermis. The pigment is the deepest layer of the epidermis, and it is there that we find pigmentation most marked. As the cells become older and grow toward the surface they lose their pigmentation, until when they reach the surface there is almost no pigmentation present. This would seem to indicate that the protoplasm, as found in the stratum Malpighii, has a selective action upon the coloring matter that may be found in the serum of the blood which is exuded at that point and taken up by the deepest layer or cells and transformed into pigment. The same selective action takes place in the coloring of the red blood corpuscles. It is perfectly reasonable to expect the epidermal cells of the stratum Malpighii to have the same power of selection, and they would get pigment out of the vegetable coloring matter of the serum that is found in contact with them. It is true that there are no blood-vessels which pass through the basement membrane, so-called, into the epidermis itself. It is also true that the cells of the epidermis are permeated by canals in all directions through which the serum of the blood passes. That point has been demonstrated very nicely by quite a number of observers, and I have beautiful photomicrographs showing those canals and the separation of the cells by those canals, so that the process is not necessarily one of osmosis, but of direct channel circulation independent of blood-vessels, no blood corpuscles, however, being found in the epidermis.

In 1885, in connection with Dr. Garretson, now dead, in Philadelphia, I carried on a line of experiments in this direction, following operations for epithelioma and other tumor conditions, to substantiate the theory of Dr. Garretson, that if the scar should be covered over with epidermis there was less possibility of return of the tumor. We made a great many experiments, and in our work we used the cuticle of a horse and scrapings from the cuticle of those students who were willing to submit to it, and among them we had the scrapings of the cuticle from the arm of a colored man, simply taking the epidermal cells, not scraping deep enough to draw any blood, which would indicate that we had not gone through the deeper layer. All these scrapings from the horse and the cuticle of the students tended to take hold and grow, particularly where antiseptic conditions were strictly observed. In the case where the scrapings were taken from the arm of the negro we had in time the development of more or less pigment, but not to the same extent as found on the original subject from which the cuticle was taken. It showed to me at that time a fact which was conclusive, namely, that the epidermal cells had the power of acting upon the fluid nourishment carried to them from the blood and manufacturing their own pigment. They had a selective action, whether they came from the deepest layer of the epidermis, the stratum granulosum or the stratum cor-

neum, and when brought in contact with the serum of the blood on a denuded surface they developed typic skin and pigment to a certain extent. These experiments were interesting to me, because it was the first time my attention had been directed to the selective action of cells, although I had held that theory for a considerable length of time. It was interesting, furthermore, because of the fact that at about that time the theory was advanced of the transmutation of connective tissue cells into epithelial cells; and the theory was also advanced that the pigmentation came from the transformation of these migratory connective tissue cells, which were supposed to enter the epithelium through the basement membrane.

Another point was brought out in my experiments regarding the stratum Malpighii, and the essayist has referred to it in speaking of the location of the pigment. The deepest layer of the stratum Malpighii, which lies in contact with the capillaries of the blood vessels, is composed of undifferentiated cells. That is, as we understand the cell, it is made up of a nucleus, cell body and cell wall, and the cells of the deepest layer of the stratum Malpighii have no cell wall, and there is no differentiation except that which is assumed in the hardening process of these cells. They lie there as a layer of nuclei in the midst of a layer of protoplasm, and differentiation of cell body comes later as the cell crowds toward the surface. As we get up toward the stratum granulosum, we have the cells divided and find a cell body and a cell wall. This division is caused to a certain extent by the channels which form between the cells extending toward the surface, but to a great extent it is mechanical. As we get nearer the surface, we have the differentiation complete. Where we find pigmentation going on there is no marked differentiation of cell body from cell body, although the nuclei are well formed and stand as palisades on the so called basement membrane. Pigmentation is located, as the Doctor has indicated, on the upper side of this basement membrane.

Dr. EMIL RIES—I am not able to say very much about grafted skin and the growth of pigment in the grafts of skin. I have done some work on pathologic skin in the human (white) being. There are a number of processes accompanied by loss of pigment and by a superabundance of pigment. One disease which I studied for a little was psoriasis, which shows very remarkable conditions of change in pigmentation. The psoriasis efflorescence looks white as a rule. This whiteness is not due to loss of pigment, but is due to air getting in between the scales of skin, which scale off from the surface, so that this surface then reflects light more than the original healthy skin does. But when we scrape off these scales we find that the skin underneath looks paler, whiter than the surrounding skin. On microscopic sections we find the pigment contained in the chromatophores, which are visible in the human skin. The chromatophores in the psoriatic efflorescence are quite as frequent and quite as full of pigment bodies as the surrounding skin. The fact is that in some cases the chromatophores are more frequent than in normal skin. In the cell layers of the epidermis itself, there is less pigment in the psoriatic skin than in the surrounding healthy skin. Some interesting observations are to be noted of psoriatic skin when the chrysarobin treatment is used. You doubtless have seen cases treated with chrysarobin where the surrounding skin at first assumes a very dark color, while the psoriatic efflorescence looks white, stands out very pale in comparison with the surrounding skin. If you examine such skin microscopically, you do not notice any further change. The change of color is not due to any change in the pigment in the cell layers of the epidermis or the chromatophores. The discoloration is not due to a change in the pigmentation contained in the cells of the normal epidermis, but it is due to the artificial substance which we apply to the skin, and it is not proven that there are any marked changes in the chromatophores or in the pigment contained in the skin. When the psoriasis heals and the diseased skin returns to its normal condition, we do not notice any difference between the original efflorescence and the surrounding skin as far as pigmentation goes. The greater number of chromatophores, which are present in diseases underneath the efflorescence disappear. I have experimented on pigment in the chromatophores and in the skin, and I have tried to find whether there were any special changes in their micro chemic reactions, etc., but I was not able to find them. A great many investigators have worked on the pigmentation of the skin in processes which are characterized by loss of pigment, partial albinism, defects of pigment after papular syphilis, the premature turning gray of the hair, and other conditions, but it would take us too far to discuss all of these conditions. But from a pathologic standpoint, the changes in the chromatophores are marked. The presence or absence of pigment in the epidermis is an important point. Among the

skin pathologists the generally accepted theory was that the chromatophores bring the pigment into the epidermal layers. When we learn that the epidermal layers themselves produce this pigment, we will have to look at the chromatophores in an entirely different light. The question arises, what is the function of the chromatophores? Dr. Loeb has found that the epidermal cells begin to migrate into the connective tissue. Now, it is perfectly possible that the chromatophores are originally epithelial cells, although I am not able to make any positive or definite statement regarding that point.

Dr. JAMES G. KIERNAN—I would like to ask Dr. Loeb whether, from an ethnologic standpoint, certain other factors should not be considered in connection with this subject. It is practically accepted by ethnologists, that the negro is developed from a lower phylogeny than the so called Caucasian and Mongolic races. Going down in the scale of evolution one thing is noticeable, as Dr. Sudduth has pointed out, that the cells possess in certain instances greater individualistic functions. In other words, in passing down in the scale of evolution, the individualistic character of the cell increases. As we pass upward in the scale of evolution, we find the cell confined to fewer functions, but losing to a considerable extent, and in many cases altogether, its powers of reproduction. I would like to ask Dr. Loeb whether that biologic fact has not something to do with the fact that he has pointed out, namely, that the pigmented cells have less tendency to degenerate into the connective tissue cells, and also whether it does not explain the fact to some extent, that a very large majority of the wounds received by negroes remain white and not pigmented. That has been my experience in making autopsies among the pauper and degenerate classes. It might explain also why there are numerous exceptions to that. Occasionally, as I have noticed, old wounds in negroes are not only not paler in type than the surrounding skin, but are actually blacker. Furthermore, I would like to know whether the same fact and some other facts that he has pointed out would not have a bearing on vitiligo as it occurs in negroes, secondary to apoplectic conditions, parietic dementia, and secondary to true apoplexy.

Dr. C. F. PINKARD—The point brought out by Dr. Ries in speaking of psoriasis, namely, that the color of the skin is not due to a change in the amount of pigment, corresponds with the condition in the iris. For instance, different colored eyes have practically the same amount of pigment; it is simply the arrangement of the pigment that makes the different colors. In the skin, the depth of the pigment below the surface is the important factor.

Dr. LOEB (closing the discussion)—I can not contribute anything which will satisfactorily answer Dr. Kiernan's questions. The influence of the nervous system upon the chromatophores has given rise to the writing of several papers. Undoubtedly, there is some connection between them, but as this work has not been fully demonstrated, it is a little premature to say anything definite about it. The view that there are channels in the epithelium is, I think, generally accepted. As to the theory or supposition that the epithelial cells select their own food from fluids that they get from the connective tissue meshes, and that this different selective power of different epithelial cells causes their difference in pigmentation, we must regard this simply as a hypothesis. As I stated in my paper, we have no fact that demonstrates that it is just hemoglobin received from the fluids which enables the epithelial cells to produce pigment. So far as my investigations go, there is very little to show that there is such a selective action on the part of the epithelial cells, as has been stated. Indeed, there are some facts entirely against it. If we regard pigmentation of the epithelial cells in the light of regeneration, we see that very often the epithelium is entirely without connection with the underlying tissues. Nevertheless the process of pigmentation takes place just the same. On the whole, we seem to agree in the belief that the epithelial cells themselves produce pigment. Dr. Ries mentioned some interesting facts about pigmentation in psoriasis. It is right that we should collect facts regarding pathologic changes in the skin, but we must consider it often difficult to give a satisfactory explanation from pathologic specimens. We do not know how this comes about. Dr. Ries also mentioned the migration of epithelial cells into connective tissue. This can occasionally be observed in the process of regeneration.

Chicago Ophthalmological and Otological Society.

Regular Meeting, Nov. 8, 1898.

Dr. COLEMAN occupied the chair. After the minutes of the previous meeting had been read and approved, the society voted to become affiliated with the Chicago Medical Society. Dr. CLARK W. HAWLEY reported a case of traumatic catar-

act with dislocation of the lens, as follows: A young man was injured in the left eye from the concussion of a gun, about a year ago, following which cataract was first noticed, and within a few weeks. Two weeks ago needling was done, a small hole being made in the capsule. The next morning, for the first time, it was noticed that the lens was dislocated, being turned upon its vertical axis, the anterior edge touching the cornea, and the anterior surface looking toward the temporal side. It was very much swollen. On consultation with Dr. Starkey, it was decided to let it alone. The lens substance protruded through the pupil, some of it hanging over the lower border of the iris; it slowly became wholly opaque and smaller, without any irritation of the iris or pain. At present the lens is rotated backward, so that the anterior surface points almost directly forward, a little to the temporal side, and the lens is dislocated toward the temporal side. The border of the nucleus can be seen almost at the temporary pupillary edge. Reaction to light and light perception and projection are good.

Dr. BULSON reported a case of mastoiditis and sinus thrombosis with operation and recovery. In conclusion, the following features were brought out: 1. The development of well-marked sinus phlebitis, with probable thrombosis after apparent recovery from abscess of the mastoid antrum, which had been thoroughly evacuated. He attributes this to infection arising from carious bottom and inner aspect of the large cell at the apex of the mastoid process, which was probably overlooked at the time the mastoid operation was performed. This carious process, easily overlooked in the mastoid antrum, owing to small area of presentation in that cavity, undoubtedly involved the inner table at the time of the mastoid operation, and if removed at that time would have obviated the necessity of a second operation. 2. The final disappearance of this phlebitis and probable thrombus without the development of other pyemic manifestations, such as pulmonary infarcts or abscesses in other portions of the body, or a fatal termination. 3. The development of an epidural abscess somewhat remote from the site of the carious process, and not discovered or suspected at the time of the second operation. This was probably occasioned by the burrowing of pus from the original mastoid abscess and subsequently becoming walled off by adhesive inflammation. 4. Demonstrations of the necessity of thoroughness in mastoid operations, which should not only include free opening of the mastoid antrum and obliteration of pneumatic structure, but careful search for and removal of small areas of diseased or carious bone.

Dr. STARKEY—The case is interesting from two standpoints: 1, that of the surgeon; 2, that of the physician. It is instructive as outlining the thorough operation that is necessary in such cases. On the other hand, it shows how some cases that are apparently very desperate will recover without further operative interference. It shows, too, that desperate cases occasionally get well, and that very extensive disease processes can be relieved and restoration follow.

Dr. F. C. HOTZ—There was evidently in Dr. Bulson's case thrombosis of the lateral sinus. I do not remember, in listening to the paper, whether the doctor said in exploring the sinus with a hypodermic syringe he drew any blood or not.

Dr. BULSON—I did not.

Dr. HOTZ—I believe you stated you did not get any pus.

Dr. BULSON—Yes. That is the reason I suspected there might be a fibrinous clot.

Dr. HOTZ—The course of infection may have been from the mastoid or the tympanic cavity. This case calls to my mind a case of thrombosis of the lateral sinus that occurred early in my practice, in which the patient had recovered apparently from an acute otitis media with perforation of the membrana tympani. He had recovered so well that at my last visit to the house, which was on Saturday, I told him that next Monday he could go down to his business. He felt perfectly well; was up and about the house until Sunday night, when he was suddenly taken with a tremendous chill, which was followed by a high temperature, and in a few hours unconsciousness. I was called in the morning (Monday) and found him unconscious, with an icteric color, high temperature, swelling behind the ear, extending downward, following the jugular vein. The patient did not recover. After several chills he died that (Monday) night. I obtained permission to open the skull. A clot was found along the sinus, adhering to the wall, but not obstructing the entire lumen. That accounted for the fact that no evidences of thrombosis had been discovered, although that fibrinous clot had certainly been forming some time: but the blood circulated through the sinus in spite of the clot, and the patient manifested no symptoms of such disturbance. Death was caused by multiple emboli in the small meningeal arteries. The thrombus extended from the sinus into the

jugular vein and was decidedly friable. I saw that a large piece had broken off from the end, and in the circulation it had been split up into numerous little particles, which went from the venous into the arterial current and probably lodged in the cerebral arterioles.

Dr. BULSON (closing the discussion)—I have but few remarks to make. The case reported presented so many interesting features that I could scarcely cover them in the condensed paper presented to you this evening. The results secured were highly satisfactory in consideration of the fact that an unfavorable prognosis had been given to the members of the family prior to the second operation, my belief at that time being that the patient would die from pyemia. In answer to Dr. Hotz' question relative to exploration of the sinus with a hypodermic needle, I will say that the needle was plugged into the sinus twice without obtaining anything that would indicate the character of the vessel. I felt reasonably certain that a thrombus existed, but heeding the advice of a prominent Indiana surgeon who was present at the operation, I concluded not to open the sinus, though I think I should now do so in a similar case if opportunity presented itself. Inasmuch as a large hypodermic or aspirating needle could not be obtained promptly when desired, I could not be certain that pus or blood was not obtained because the needle was so small or because it was thrust into a well-developed fibrinous clot. Judged from the feeling and tenseness, which latter seemed to extend well down into the neck, I feel certain there must have been a thrombus there, doubtless involving the outer lumen of the vessel, if not completely occluding it. Recovery may be attributed largely to good nursing and a strong constitution, the patient being a man weighing fully 190 pounds and the picture of health. The epidural abscess was undoubtedly due to infection, probably from a portion of the carious process overlooked at the time of the original mastoid operation. The operation lends added force to the idea that a mastoid operation should be thorough. I do not believe that it is good policy or surgery to rest easy with simply puncturing a little hole in the mastoid antrum, or, as frequently happens, into a large pneumatic cell, and by the evacuation of a little pus think that the patient is going to get well without complications or further operative procedures. Where carious bone exists, and this is especially true in long-standing cases, the patient will never get thoroughly well until the carious bone is removed, and this can not be done unless the parts are thoroughly exposed so that they can be inspected with the naked eye and the operation done in a thorough and systematic manner as required. It has always been my policy to thoroughly open the mastoid antrum, and to carry the curette in every direction until solid bone is found, and as long as any soft or carious bone is detected to keep on with the operation until the same has been completely removed. Unless great care is exercised small spots or channels of carious processes may be overlooked, as was probably the case in the instance cited. Considering the gravity of the case reported and the extensive operation required for relief, I am very glad to be able to report satisfactory results and the recovery of the patient.

Dr. COLEMAN—With reference to dressings, speaking generally, would you pack the wound for a considerable time or for a short time?

Dr. BULSON—That depends largely upon the nature of the case and the operation. If there is considerable pus being formed I remove the dressings and irrigate. As a rule I do not irrigate. I suppose you refer to mastoid operations?

Dr. COLEMAN—Yer, sir, and I want to know whether you would repack a wound for two or three weeks as a rule. There are exceptions in which you might pack it for two or three days and then allow the wound to heal.

Dr. BULSON—In a simple mastoid operation I aim in the first place to establish a connection between the middle ear and the mastoid antrum, so that an antiseptic solution injected into the fistulous opening will pass out at the meatus. The wound, including mastoid antrum, is then lightly packed with a dry gauze dressing, and unless there is a rise of temperature this dressing is not disturbed for a period of four or five days, when, if the wound is found to be dry, the dressings may be removed and the fistula allowed to close. In some instances, in order to facilitate drainage, the dressings will need to be replaced frequently for several weeks.

Dr. GRADLE presented a new instrument for the removal of the enlarged pharyngeal tonsil in one piece and showed some specimens illustrating its efficiency.

Just Ordinary Substitution.—Customer (in bookstore): I want to look at some bibles. Clerk (formerly with druggist): We're just out of 'em. We have something just as good though.—*N. York Journal.*

Cincinnati Obstetrical Society.

Nov. 10, 1898.

Dr. A. W. JOHNSTONE reported an extirpation of a myomatous uterus. He was unable to find any ovary on the left side. There was only a small left uterine artery and absolutely no vestige of the ovarian artery upon the left side. There was only one ovary and tube. There was no evidence of previous surgery. The cervix was displaced to the left side. In doing the operation, the cervix was split and left. In this way good drainage was secured and the case recovered nicely.

Dr. EDWIN RICKETTS presented a photograph of a tumor weighing sixty-five pounds, removed by total extirpation from a woman 52 years of age. Death occurred after thirty-five hours, the immediate cause of death being unknown.

Dr. RUFUS B. HALL presented a specimen removed from a case of extra-uterine pregnancy. The specimen was a fetus six inches long, with the placenta forming the sac, which was not ruptured in its removal. The fetus had been dead for some time. Convalescence easy.

Dr. A. W. JOHNSTONE believed that the specimen presented by Dr. Hall represented the first step toward the formation of a lithopedion. In this case the specimen showed evidence of infection, which emphasizes the necessity of surgical interference in these cases. During the meeting of the AMERICAN MEDICAL ASSOCIATION in Cincinnati, it was held by some that an operation was unnecessary in these cases, which assertion the case just reported would tend to disprove. Even a lithopedion ought to be removed, for a woman is never safe with the results of an extra-uterine pregnancy in her abdomen.

Dr. S. STARK gave a brief abstract of a report that recently appeared in the *Centralblatt für Gynekologie*. The case was one of tubal pregnancy with the history of repeated ruptures. Abdominal section revealed the child free in the abdominal cavity, among the intestines. There seemed to be no reaction whatever on the part of the peritoneum. There was no amnion, and evidently the fetus had been passing its urine and discharges into the free peritoneal cavity of the mother without doing any damage. The placenta, which was adherent to the remaining portion of the tube and over the surface of the uterus and bladder, was removed with difficulty only at the end of four weeks. It took two weeks longer for the wound to heal. A ventral hernia remained, which was operated upon six or eight months later. At that time all the adhesions formed from the lymph thrown out had disappeared. The child was alive.

Dr. EDWIN RICKETTS reported a case of extra-uterine pregnancy upon which he had operated. The fetus was found out among the intestines. There were no adhesions. The fetus was pale in appearance, apparently blanched. He succeeded in removing the placenta at the time of the operation.

Dr. JOHNSTONE called attention to the fact that in the case of the first living child removed in the way described, the conditions found were exactly similar to those described by Dr. Stark. There were no adhesions, no amnion, and the child was free in the abdominal cavity. We must not forget that the placenta may keep on growing even after the death of the fetus. Septic infection is the greatest risk in these cases.

Dr. HALL, in closing, stated that he believed there had been, in the case he reported, several hemorrhages of considerable size, and that nature had attempted in each instance to absorb the blood. After one of the hemorrhages the woman appeared as large as at the sixth month of pregnancy.

Dr. MAGNUS TATE read the regular paper of the evening,

THE TRANSMISSIBILITY OF MORPHIN.

He gave a brief review of the literature and reported cases of transmissibility of drugs to the child through the mother's milk. The more important drugs affecting the child through the mother's milk are belladonna, effect constant; potassium iodid, effect not uniform; mercury, effect very feeble and only after prolonged administration; saline cathartics, effect not constant; quinin, through the use of which a fatal illness has been reported; arsenic, if given in sufficient quantity; salicylates, if given in sufficient quantity; opium, effect inconstant, but may produce toxic symptoms. A confirmed morphin-user is known by pallor, emaciation and contracted pupils. But none of these symptoms were present in the cases observed by the essayist, nor was there any atrophy of the genital organs. He believes that morphin in small doses will not affect a healthy pregnant woman differently than if she were not pregnant. Such doses constantly repeated will produce a marked effect upon the gastro-intestinal system, and this may be followed by a train of nervous phenomena, which may not only seriously affect the health of the patient but that of the fetus, and an abortion or premature labor may result. The taking of large

doses means danger to life of both the patient and fetus. The essayist noted the effect of morphin, gr. $\frac{1}{8}$ to $\frac{1}{4}$, given hypodermatically to thirty women after labor; pains were good and strong and the os dilated to the size of a quarter. During the first stage pains were reduced in frequency, became lighter, and in eight cases ceased from one to two hours. During the early part of the second stage the effect was not constant; in a few cases the pains were lessened in force and strength, but in no case did they cease. Later on in the second stage, there was no effect whatever. In two cases, in which the cervix was rigid and unyielding, morphin caused relaxation and softening and labor terminated normally. In a normal case of labor, in a healthy patient, morphin does not predispose to postpartum hemorrhage when the drug is administered in ordinary doses, gr. $\frac{1}{8}$ to $\frac{1}{4}$. There were no cases of postpartum hemorrhage in the thirty cases reported. Small doses of morphin taken by the mother may not be and generally are not discovered in the milk, because the clinical evidence is not strong enough to point to the source of the existing evil. Larger doses produce such marked symptoms in the infant, that it seems rational to make the statement that morphin, if taken in sufficient quantity by the nursing woman, will readily be transmitted to the infant. For the detection of morphin in the milk, he used Kalkbrunner's test, consisting of two solutions. The first solution is ferric chlorid, grs. 30, water $\mathfrak{z}\text{iv}$; the second solution, potassium ferricyanid, grs. 2, water $\mathfrak{z}\text{iv}$. Add to the suspected fluid five or six drops of the first solution, then three or four drops of the second solution. If morphia is present, the color will change to a pale green or deep blue, depending upon the amount present. In the absence of morphia the color is a dirty gray.

Dr. EDWIN RICKETTS referred to a case in which the administration of small doses of morphia to the child stopped convulsions that were probably caused by the mother receiving hypodermatic injections of morphia. It was necessary to continue the drug several weeks. The child still lives.

Dr. STARK thought the case indicated that morphin does not pass through the placenta, or the child would have acquired a tolerance to the drug.

Dr. JOHNSTONE thought this could be accounted for by a difference in the rapidity of elimination through the placenta and through the breast. The child might get a much larger dose through the breast than through the placenta. He reported a case in which a child was born of a mother who used morphin. The child never nursed. At times the child had irritable spells, which could only be quieted by the administration of paregoric. The child seemed to have become addicted to the opium habit. In another case morphin was given for severe after-pains. The second or third day the child seemed to go to sleep and died. It seemed likely that the child had been poisoned by morphin excreted in the milk.

Dr. PALMER believes we may affect the child in utero by administering morphia to the mother, but the quantity of morphia must be much larger than would affect the child when taking the mother's breast, later on. Morphia diminishes the activity and painfulness of the contractions in parturition, and is one of the best remedies we can give when the uterine contractions are extremely painful and when there is a want of normal dilatation of the cervix uteri in the first stage of labor, but morphia is not so good as chloroform by inhalation in such cases. Another agent which has a marked influence upon the lacteal secretion is large quantities of whisky and beer. Children at the breast may be made drunk by the nurse taking too large quantities of these beverages.

Cincinnati Academy of Medicine.

Meeting held Oct. 31, 1898.

Dr. C. R. HOLMES reported a case, and showed the patient, whose left eyeball had been injured by a thirty-eight-caliber ball fired at a range of two or three feet. The victim had been leaning over a table at the time, so that the plane of the anterior part of the face was directed almost horizontally backward. The ball struck the orbital plate and without splintering it or causing fracture of any part of the skull, passed downward, injuring both lids, and buried itself in the cheek, from which it was removed. It had not caused a rupture of the skin, but the force of the impact against the eyeball had injured the inner tunics of the eye, resulting in hemorrhage into the vitreous, and a lenticular opacity. He exhibited the bullet, which was greatly flattened.

Dr. HORACE WHITACRE presented a patient who had been injured some weeks previously by a severe blow on the head, the result of the latter coming in contact with the wheel of a heavy wagon. He was seen a few minutes after his injury,

was not unconscious, but exceedingly restless and irritable. The principal symptom was the slow pulse, about 52, subsequently diminishing to 46. There were no localizing symptoms and no paralysis; some little time after the injury there developed a subconjunctival hemorrhage on the left side; there was a large hematoma present on the back of the head. The symptoms becoming worse and the patient sinking into a condition of unconsciousness, it was decided on consultation with Dr. Frieberg to trephine. The second opening in the temporal region exposed a large clot between the skull and the dura. The opening was enlarged and the bleeding point tied. About two handfuls of clotted blood were taken away. The dura was not opened, as it was thought that the clot found fully accounted for the symptoms. The result, uninterrupted recovery, proved the soundness of this view.

Dr. C. A. L. REED reported three cases of cholelithiasis. In the first case an additional diagnosis of chronic recurring appendicitis was also made. On removing the appendix he found by carrying his hand upward toward the liver that the gall-bladder was greatly distended. The primary wound was sewed up and the regular incision for gall-bladder operation was made; 380 gall-stones, remarkable for their almost uniform size, were removed. In the second case the gall-bladder was greatly distended, but on opening it no stone was found, three pints of fluid, however, exuded from the gall-bladder. Search revealed a large stone in the common duct, which was removed by a linear incision. The patient made a good recovery, but that very day, fully two months after the operation, he had presented himself again with jaundice. The speaker did not believe this to be due to another stone, but that cicatricial contraction in the line of incision of the common duct had caused a stenosis of this duct, and that another operation would be necessary to relieve this condition.

Dr. FRIEBERG mentioned some cases, operated on by Mc Burney, in which an opening was made into the duodenum and the stone lodged in the common duct delivered through the papilla, the object of this operation being to avoid the troublesome stenosis that had occurred in Dr. Reed's case.

Dr. REED said that he had made the operation, but that the difficulty of knowing just what part of the gut to open, and the greater difficulty of finding the mouth of the common duct were serious objections to the operation. The third case reported by Dr. Reed was one of gall stone colic recurring at frequent intervals for twenty-five years. Operation revealed a stone impacted in the cystic duct, and a large number of smaller stones behind it.

Dr. MEYER HEIDINGSFELD presented a patient whom he had been treating with electrolysis for nevus. Two milliamperes was the current used, conducted by a steel needle attached to the negative pole, the point of the needle reaching into the true skin so as to avoid extensive scarifying, though he admitted that cicatrization proceeded more slowly by this method than if the needle had not sunk so deeply.

Dr. RICKETTS reported a case, and exhibited a specimen, of a large ovarian cyst weighing twenty-five pounds. He also showed a specimen of a large dermoid springing from an ovary.

Dr. B. F. LYLE exhibited a specimen of aneurysm of the thoracic aorta, about the size of a walnut, situated at the junction of the ascending and transverse portions of the arch. The patient had died suddenly, but the aneurysm had not ruptured. A thickened condition of both apices of the lungs was also present (examination of the sputum had proved tubercle bacilli to be present).

Dr. E. W. MITCHELL reported a case of what he believed to be angina pectoris with fatal termination, in a man 58 years of age. He had never been subject to attacks before, nor did his history of the case throw any light on his present illness. His symptoms were sudden, violent, *constricting* pain under the sternum, radiating down both arms. The heart felt like it were being held in a vise. He did not fall or lose consciousness, but was very sick and nauseated. Dr. Mitchell had thought him to be suffering from an anginal attack, but the acute symptoms being over and the circulation somewhat depressed, he thought the nitrates contraindicated and gave the patient 1.30 gr. strychnia by the mouth and 1.50 gr. digitalis by hypodermic injection. The pulse rallied somewhat, but suddenly he noticed a marked blanching of the face and, feeling for the pulse at the wrist, could find none. Respiration continued fully two minutes after the entire cessation of the heart's action. Dr. Mitchell looked upon three causes in the etiology of sudden death: he ruled out the brain in this case, for the patient, after his primary attack, had conversed genially with his friends and was perfectly conscious of his surroundings. He thought that the continuation of respiration for some minutes after the heart had ceased action would rule out any involvement of the respiratory apparatus. In

addition, examination of the lungs had been entirely negative. Examination of the heart had been negative also, as far as the presence of murmurs was concerned. He knew that no diagnosis could be made in this case without a postmortem examination, which he had unfortunately been unable to obtain. He might, indeed, have been suffering from an aneurysm or thrombosis of the coronary arteries. He based his diagnosis of angina pectoris entirely on the history.

Dr. T. LOUIS BROWN reported a case of foreign body (hog's bristle) almost an inch long imbedded in the left tonsil; removed.

Meeting of Nov. 14, 1898.

Dr. C. D. PALMER read the regular paper of the evening,

WHAT IS THE PROPER FIELD OF SALPINGO-OÖPHERECTOMY?

The paper was along the line of conservatism in gynecologic surgery. As to when and to what extent we are to sacrifice the ovaries and tubes, he thought the removal of the ovaries should be done more frequently than that of the Fallopian tubes. Often in an attempt to remove the ovaries, inadvertently the tubes are also taken out. In point of danger, there is little difference whether one or both of these organs are removed. The removal of either organ on either side renders the other of the same side practically useless, in a procreative sense. Of more importance is the extent to which the ovaries are sacrificed. Their removal, as a rule, means an abrupt and immediate cessation of menstruation, an artificial menopause. The menopause of any woman, especially if young, abruptly induced, is attended with phenomena of the nervous system, more pronounced in perturbations, more enduring in results than is the natural cessation of menstruation. The menopause is commonly attended by atrophic anatomic changes in the genital organs. Exceptionally, menstruation continues indefinitely, notwithstanding attempts to completely extirpate both ovaries. Such cases may be attributed to improper ligation of the broad ligament, as to depth or location, and the unintentional leaving of some ovarian structure. The essayist advised the operation: 1, to abrogate the process of ovulation; 2, to check or modify the menstrual discharge; 3, to remove organs incurably diseased.

As to when we are justified in making a Battey operation for certain nervous diseases, the essayist believed the operation indicated only when the nervous phenomena can be traced to or are limited by ovarian action, or when some serious organic ovarian morbid change, in kind or in degree, can be detected by the bimanual touch, with or without anesthesia. He did not advise the Battey operation for dysmenorrhea, except when due to structural disease of the ovary.

As to what extent we ought to disturb the ovaries for uterine disease, he thought such an operation of well-recognized value in the treatment of small interstitial uterine fibroids. In such cases the prevention of a possible pregnancy is another argument in its favor. When a Caesarian section is made for a seriously contracted pelvis, the essayist would advise tying the tubes and leaving the ovaries. The detection and thorough removal of the ovaries in cases of uterine fibroids of much size, is always difficult and the results very uncertain. Uterine displacements not otherwise remediable may be relieved by surgery. In such cases the appendages should be removed if found to be diseased. The uterine appendages should be removed when seriously and hopelessly involved in disease. A partly diseased tube may recover if well emptied after abdominal section, by aspiration or the passage of a probe into the ampulla followed by finger compression. Purely catarrhal salpingitis, the most frequent form, never needs section; cases of hydrosalpinx usually do; hematosalpinx and pyosalpinx almost always. In the way of medicinal and hygienic treatment, the essayist advised rest in the recumbent posture, purgation early in acute cases, by the use of salines. Daily movements should be secured. Counter-irritation, with small fly blisters, do good in chronic cases. Cold or hot applications are best for acute cases. Sthenic cases may be given minute doses of aconite or veratrum viride. Generally no internal medicine equals quinin. Opium is to be avoided as much as possible, and is best given in rectal suppositories made of the aqueous extract. Specific cases call for the hot sublimate douche, otherwise boric acid is preferable. For chronic cases no medicament is superior to ichthyol diluted with boroglycerid. Churchill's tincture of iodine may be applied to the vaginal vault in such cases. As a rule, minute doses of bichlorid of mercury are preferable to the use of iron. The bromids diminish pelvic congestion and are sexual sedatives. Hemorrhagic states of ovarian origin may call for sodium bromid. In old cases the use of electricity may resolve pelvic exudates, relieve pain and control local neurosis. Salpingitis is almost always an outcropping of an endome-

tritis. In such cases the uterus should be curetted and packed. Follicular ovaritis should not be mistaken for cystic degeneration. In cases of cystic degeneration of the ovary, a simple puncturing of the larger cysts, after section, will answer for not a few cases. Most cases require no surgical treatment. The essayist advocates saving as many and as much ovarian structure as practicable, but believes it rare that the corresponding tube may be saved. The uterus and appendages should be removed when the uterus is so contaminated with disease that it is advisable to cut off the whole septic field and give full drainage. Thus, the operation is called for in post-puerperal cases, next in specific, and least frequently in septic non-puerperal cases.

After all abdominal sections for supposed diseases of the uterine appendages, we should carefully inspect them for macroscopic evidences of disease. Only such parts of the appendages, the ovaries in particular, should be removed as may be hopelessly diseased. The healthy side should not be disturbed unless for good and sufficient reasons. Slight cystic degeneration or cirrhosis of the ovaries is insufficient grounds for their extirpation.

In closing, the essayist inquired: Has as much consideration been given to the salvation of the uterine appendages as is devoted to the preservation of the analogous organs in the male?

Dr. C. L. BONNIFIELD believed that if more attention were paid to the acute inflammations in the beginning the abdominal operators would have less to do. He would not recommend the removal of the ovaries to stop the growth of tumors. Myomectomy and hysterectomy have been so perfected that they are much more safe than formerly, and after such operations the trouble is absolutely cured. The removal of the ovaries will stop these growths only when they can be removed the easiest. The woman never feels completely contented as long as she feels she has a tumor. Whether or not to remove the ovaries when the uterus is removed, is a question that is as yet *sub judice*. He agreed with the essayist that the ovaries should not be removed for nervous diseases, unless we can prove that they are diseased. A few cases have been reported cured by the removal of the ovaries, but such cases would probably have been cured by any extreme method, which would have produced considerable shock upon the nervous system. He had never seen a case of uterine hemorrhage, not attended by fibroid, which could not be controlled in some other way.

Dr. RUFUS C. HALL thought that frequently we erred on the wrong side in our enthusiasm to save one ovary or as much as possible of an ovary. Where we are obliged to remove one ovary for disease that is not infectious, we may often save the opposite ovary or part of an ovary. But such great conservatism is not justifiable in pus cases, either gonorrheic or septic. Dr. Hall had, on a number of occasions, left an ovary or part of an ovary with apparently good immediate results, but months or years afterward he had been obliged to remove the ovary left at the first operation, even in non-infectious cases. Five or six of his patients, in whom an ovary or piece of ovary was left, have since borne children. Dr. Hall did not believe it safe to leave the opposite tube in cases of pyosalpinx. He had never seen a pyosalpinx on one side with a perfectly healthy ovary and the tube on the other side. In cases in which there is a prolapsed ovary with a retroverted uterus, the condition should be corrected before the long continued engorgement causes adhesion.

Dr. A. W. JOHNSTONE had recently operated upon two cases in which there was only a papillomatous degeneration of the ovary to account for one to three pints of fluid in the pelvis. He believes that much of the trouble usually ascribed to the menopause is due to American gout. Often there is the history of English gout in the ancestry. If these attacks appear after the production of an artificial menopause, they would appear at any rate a few years later, after the natural menopause. He did not think it prudent to leave a piece of the ovary for the purpose of not bringing on the menopause which only holds out the prospect of holding another ovariectomy to get it out.

Dr. J. M. WITHROW heartily endorsed the conservatism in gynecologic surgery recommended in the paper of the evening, and believed there could be no question as to the utility of the removal of the ovaries for fibroids or bleeding of the uterus. The reported successes following the removal of one or part of one or both ovaries, even in cases of septic infection, certainly justifies a trial. He believes that the artificial menopause is much stormier than the natural menopause, and had never seen a case in which he felt constrained to remove the ovaries for dysmenorrhea, but he could conceive that such cases might exist.

Dr. EDWIN RICKETTS thought conservatism could be carried too far. He compared the conservatism of the essayist to the wave of conservatism that followed the general adoption of ovariectomy. In no case is the vaginal route to be preferred for the removal of the ovaries and tubes. When there is a hematoma of one ovary, it is better to remove the other even though it may appear healthy at the time. Dr. Ricketts had seen cases of fibroids develop in spite of the removal of the appendages, and total extirpation later became necessary.

Dr. E. GUSTAV ZINKE paid high compliment to the paper of the evening. He objected decidedly to the statement, by the previous speaker, that the ovaries and tubes ought never be removed by the vaginal method. He had operated on a number of so-called pelvic abscesses by the vaginal route entirely. He had a record of at least twelve cases in which he had evacuated the pus through the posterior cul-de-sac. All the patients recovered without any difficulty, and at least one of them has since given birth to a child. Of course, pyosalpinx can not be dealt with readily by the vaginal route.

Dr. PALMER, in closing, stated that he had been prompted to write the paper by the realization that oöphorectomy and salpingo-oöphorectomy are done too frequently. Too many ovaries are now stored in pickling pots, which ought to be where nature first placed them. In some cases Dr. Palmer had secured good results by the curettage of the uterus in old cases of peritubal inflammation.

PRACTICAL NOTES.

Dry Sterilization of Instruments.—Metal cylinders of various lengths and sizes are used at Frankfort to hold the forceps and everything required in obstetrics. They are placed in a dry sterilizer or the oven of the cook stove and sterilized dry. The cylinders are not opened until needed and the instruments are not injured in the least by the process.—*Munich Med. Woch.*, October 25, from *Cbl. f. In. Med.*, No. 40.

Iodin in Gonorrhea.—The vagina is cleansed with boric acid water, dried and painted with pure tincture of iodine every two or three days with injections of an iodized solution three or four times a day, and the lumbar and lower abdominal regions painted with iodine. After the inflammatory symptoms have subsided, a mixture of one part pure iodine to two parts glycerin is applied to the cervical canal. If the uterine cavity has been invaded, the surface is painted with the iodine after dilation of the neck. He also administers iodide internally.—*Semaine Méd.*, November 9.

Puncturing the Intestines.—Quevado suggests puncturing the intestines through the inguinal canal in case of threatening meteorism, as free from all the objections urged against puncturing in such cases. The idea was derived from observation of the postmortem emphysema in the scrotum and vulva.—*Cronica Méd. Mex.*, November 1.

Phenocoll in Malarial Fever.—Cesare Monduri reports satisfactory results with this drug in febrile conditions diagnosed as malarial. The doses of the hydrochlorate vary from 1.5 grams to 2 grams daily for adults and from $\frac{1}{3}$ to 1 gram daily for children.—*Am. Gyn. and Obstet. Jour.*, November, 1898.

Kil, the Russian Mineral Soap.—A natural mineral soap is found around the Black Sea which is much used for sea baths, and after calcining, forms an excellent vehicle for salves, etc. It is composed essentially of silica, alum, ferric oxide, chalk and magnesium carbonate. Veliamovitch recommends it for cleansing purposes when ordinary soap is not tolerated, as in acute eczema, etc.—*Semaine Méd.*, October 26.

Peroxid of Hydrogen.—A recent communication based on five years' experience and much experimental work, lauds peroxid of hydrogen for its microbicidal and hemostatic properties, which "entitle it to the front rank in medico-surgical therapeutics, and especially in affections of the mouth and throat." It is absolutely harmless, while more strongly antiseptic than sublimate. As a hemostatic it should be indispensable to surgeons.—*Bull. de l'Acad. de Méd.*, October 31.

Sodium Bicarbonate for Hiccough.—A recent communication to the Paris Académie de Méd. reports that hiccough has always been arrested, in the long experience of the writer, with 5 grams of sodium bicarbonate in half a glass of Vichy water taken at one draught. The hiccough disappears with the eructations.—*Bulletin*, October 31.

Reviving the Apparently Dead.—Tuffier and Hallion suggest opening the thorax and rhythmically compressing the heart with the hand, after all other means of artificial respiration have failed. They have succeeded in this way in reviving dogs chloroformed until all the movements of respiration and heart action had completely ceased. In a few moments the heart commences to contract spontaneously and the respiration becomes re-established.—*Semaine Méd.*, November 2.

Orthoform in Vasomotor Rhinitis.—Lichtwitz and Sabrazès ascribe the different forms of vasomotor coryza: hay-fever, nasal hydrorrhea, etc., to hyperesthesia of the pituitary gland. This can be controlled, temporarily, by cocain, but orthoform is far more effective, its influence lasting, and free from the dangers and inconveniences of cocain. They mention, among other observations, the case of a man 34 years of age, with periodically recurring nasal hydrorrhea, sneezing, etc., for six years. A single insufflation of orthoform with a Kabierski insufflator cured him in the midst of an attack, and when seen last he had had no recurrence. (*Presse Méd.*, October 12). To prevent coughing from the dry powder, *vide JOURNAL*, p. 1306.

The "Block Bed."—The inconvenience of raising a patient to apply a bandage or cast under certain parts of the body is obviated by Professor Folet's device of having the patient lie on a set of blocks of various sizes but all exactly ten centimeters high, packed close together on a table. The idea was suggested by a doll lying on an uncovered box of toy blocks. One or more of the blocks can be removed without disturbing the patient and allow the hand or bandage to be placed around the part without the slightest inconvenience. He has the seventeen blocks in his set made hollow, like drawers turned upside down, being thus light to move, and easily packed away when not in use. The weight of the patient keeps them from slipping around under him. *L'Echo Méd.*, October 23.

Infantile Meningitis.—Carbajal writes to the *Revista Médica*, October 15, describing his successful results with a blister applied to the occipital region at the commencement of the second or paralytic period in this disease. He uses Autenrieth's salve and croton-oil, 30 to 4 gm., every four to six hours until the surface is blistered and suppurating, after which the suppuration is kept up with some simpler salve. He ascribes to this measure the recovery of all his cases since employing it, combined with the usual therapeutic measures, avoiding narcotics.

Resection of Deformed Nasal Septum.—Escat resects a C-shaped septum without perforating it completely, by injecting, after cocain, enough water to separate and distend the mucous membrane from the cartilage on the convex side (they are easily detached in the young). He then resects the convex side, including the protuberant cartilage and its membrane, at one stroke, leaving the membrane on the concave side intact. Gauze tamponade for twenty-four hours controls hemorrhage, and the operated side is soon regenerated on the membrane support.—*Munich Med. Woch.*, October 25.

Massage for Post-operative Ileus.—Häberlin has found massage through the rectum and even of the entire abdomen, very effective in promoting the passage of gas and feces after celiotomies, etc., preventing adhesences and assisting convalescence. He reports one case in which an intestinal loop was evidently becoming incarcerated in the Douglas pouch, which he released by energetic massage through the rectum. He

considers the fears of hemorrhage, etc., unfounded, but advises as a preliminary the usual therapeutic measures.—*Cbl. f. Gyn.*, 42.

Ferric Chlorid in Dermatomycoses.—Martin has found ferric chlorid very effective in curing pityriasis versicolor. Two or three applications of the following suppress every trace of the affection; dry ferric chlorid 5 gm., gutta percha 2 gm., chloroform 20 gm. For external use. Remove the traces of the gutta percha with 10 per cent. alcoholized water. He also cures erythrasma with one part chlorid to 4 parts collodion, and the inflammatory form, with a solution of 30 gm. dry ferric chlorid to 70 gm. glycerin. Cures in ten days. Trichophytiasis is also cured in an average of twenty-five days with salves or collodion applications of ferric chlorid. The stains on the skin can be removed with a solution of sodium carbonate 6 gm., glycerin and water aa 30 gm.—*Semaine Méd.*

Inefficacy of Cerebral Inoculations in Tetanus.—Recent experimentation at Rio Janeiro has confirmed the extreme sensitiveness of the nerve-cell to the action of the toxin and the protoplasm of the cell. If the toxin and antitoxin are injected combined, at the periphery, the stimulating effect of the latter in arousing the organism to defense, is felt before the toxin reaches the brain, and there is no infection; but if the infection has already reached the brain, the antitoxin is powerless to affect the results, whether inoculated at the periphery or in the brain itself.—*Tribuna Méd.*, August 15.

Chronic Nephritis.—Lemoine treats chronic nephritis with the following powders: lithin benzoate 50 cgm., betol 25 cgm., sodium bicarbonate 20 cgm. Make twenty similar powders, and take two or three during the day, between meals. If the urine occasionally becomes scanty and brownish with a few red corpuscles, he resorts to tannin: tannin and pulverized cinchona aa 50 cgm.; for one powder. Make twenty similar powders and take two powders a day with the meals, or, if the patient dislikes to take powders, it can be administered as follows: tannin 250 cgm., glycerin 30 gm., and syrup of bitter orange 120 gm. Take four to six tablespoonfuls at the commencement of the meals. This treatment should be kept up a long while, suspending it one week in four. He sometimes alternates the lithin benzoate and the tannin, a fortnight each.—*Semaine Méd.*, October 26.

Cystorrhaphy by Imbrication.—Juvara suggests suturing the bladder after suprapubic incision, by imbrication, that is, by overlapping stages, like tiles on a roof. The suture heals more rapidly by first intention, owing to the greater surface expanse, and he claims that it responds to every ideal requirement. His tests on dogs, which are exceptionally liable to infection from such a cause, as their bladder is located in the peritoneum, all proved extremely successful, even without the use of the sound. Experiments on cadavers showed that this method is exceptionally simple if the peritoneum is protected by pulling the upper part of the posterior surface of the bladder out through the wound with the fingers.—*Bull. de la Soc. de Chir.*, Bucarest, 1898, 1.

Cutting the Umbilicus.—Schrwald observes that the usual haste to sever the umbilicus results in the loss to the child of a large amount of blood to which it is entitled, sometimes reducing the blood in its circulation from the 158 grams it should have with a weight of six pounds, to 58 grams. He ascribes to this fact many cases of infantile weakness and lack of resistance to disease, congenital valvular insufficiency, etc. The cord should never be cut until all pulsation has ceased, and this applies with extra force to the apparently dead, in whom the circulation should be stimulated with warm compresses on the heart and the centers of heart and respiration action at the back of the neck. When the cord pulsates, proceed to artificial respiration in the usual way, with the arms.—*Deutsche Med. Woch.*, September 8.

Celluloid.—In the *Med. Press and Circular* for August 31, a writer states that the question of abdominal drainage incidentally involves the question of wound-drainage in general and the same arguments apply. If at the moment of operation the wound could be sealed with an air-tight material, which would remain so until healing was complete, primary union might be reckoned upon. With the new dressing, celluloid, described by Mackenzie in 1896, a transparent closely adherent film can be applied which has the advantage of contracting. Stanmore Bishop has reported three cases out of a large number to illustrate its advantages. They are ovariotomy, removal of appendix, and suprapubic lithotomy. Union by first intention was obtained in all, under one dressing. If perfect asepsis has not been secured the transparency of the dressing enables the place where it is faulty to be seen.

Tremor Toxin and Antitoxin.—Adamkiewicz considers that the pyramidal tracts inhibit the action of the muscles and the posterior columns incite it. The decay of the function explains the ataxia in tabes and the rigidity in lateral sclerosis. The attempt to move the rigid muscles results in tremor, which can therefore be considered the result of both anatomic and functional lesions of the pyramidal tracts. The tremor in the chill of commencing infective diseases is induced by the effect of the toxin on the pyramidal tracts. As this chill has a particularly deleterious effect on the organism, some means should be sought to arrest it. He has found that the addition of carboic acid to neurin (C_5H_3NO) will deprive it of its tremor-producing property while not affecting its other toxic effects, and he suggests that it may be possible to separate the tremor-producing property of the toxin in acute infective diseases from the rest, and paralyze it in a similar manner.—*Berlin Klin. Woch.*, October 3.

Arsenic as an Alterative.—Dr. T. W. Schaeffer, in the *Charlotte Medical Journal*, says that arsenic increases the elimination of nitrogen by the simultaneous diminution in the absorption of oxygen and elimination of carbon dioxide, and causes in this way a fatty degeneration of the organs. It appears that under the influence of this poison fat is formed from the proteids. The nitrogen, with a small proportion of carbon, is dissociated from the proteid molecule, and the nitrogen-free residue is deposited as fat in the tissues. So that the so-called "alterative" rôle of arsenic in therapy may be described somewhat more modernly and intelligibly: arsenic is, in fact, a carrier of oxygen; it is an oxidizer and a deoxidizer. Hence, we judge, its beneficial effects, when taken internally in small doses, in exerting a tonic effect upon the nervous system, improving the quality of blood, being an excellent hematic, of great value in ague and chronic malarial disorders, promoting digestion, and this explains why it can often be relied upon in the many forms of dyspepsia.—*N. Y. Med. Jour.*

Treatment of Asystole.—Professor Huchard's treatment of heart disease consists of rest in bed, milk diet, and if the heart is much dilated, venesection. After two or three days of this preparation a purgative is administered: scammony 50 cg.; calomel, 20 cg., in two powders, taken with half an hour interval. The day following, the patient is ready for digitalis, and all danger of intoxication is avoided by not allowing the drug to accumulate in the system. He insists upon the crystallized digitalin: 40 to 50 drops of the alcoholic solution of the Codex, at $\frac{1}{1000}$ —50 drops corresponds to a milligram of crystallized digitalin. In a few hours the edemas are absorbed and diuresis is established. Three days later, if the improvement is not sufficiently pronounced, 25 to 30 drops are administered, and this dose is repeated at intervals of ten to twenty days, for several months, if necessary, respecting the long intervals. Small doses, closer together, are the reef on which the average practitioner makes shipwreck.—*Gaz. Méd. de Liège*, October 27.

Paradism for Chilblains.—Dr. Forbes Ross of London was led to try the following procedure for the relief of chilblains, and has had invariable success during several winters. Relief has been prompt in every instance. Having ascertained and localized the focus of each chilblain, resort was had to the application of the secondary current of a Faradic battery, increasing the current gradually to high strength. The application must be made directly to the affected part, i. e., both poles must be in contact with the affected area, separated only by the area occupied by the chilblain itself. Having first previously dipped the electrodes in saturated sodium chloride solution, maintain the application of the current to each chilblain for from five to fifteen minutes. If the chilblains be watched during the application of the current the tissues will be seen to gradually blanch and the anemic area due to the pressure of the electrodes will be seen to creep outward, even though care be taken not to increase the pressure. This blanching begins after about five minutes of the passage of the current. The result of this procedure is that the itching is completely and promptly stopped by the first application, and a second, one or two days afterward, usually suffices to effect a cure. Seldom, if ever, does a third or fourth application become necessary. He has never in a single instance, in an extensive trial of this method, known it to fail to effect a cure in three or four days, to the great delight and gratitude of the victim. The treatment is handy and rapid.—*Lancet*.

Gelatin in Aortic Aneurysm.—Lancereaux of Paris, has made use of a solution of gelatin dissolved in an artificial serum for the hypodermic relief of aneurysm. In a paper before the French Academy of Medicine (London *Lancet* for October 22), he reported the results in several cases. One of his patients had an aortic aneurysm which projected anteriorly. Subcutaneous injection of a solution of gelatin in artificial serum was made, and the patient recovered. Some time previously the blood had escaped from the aneurysm and coagulated just under the skin; the patient's state was very critical, but injections of gelatin promptly brought about coagulation of the extravasated blood. In the second case the patient suffered from aneurysm of the aorta which had not come to the surface. By means of the gelatin injection treatment all the pain disappeared and the dilated superficial veins diminished in volume. Lancereaux has treated by this method many aneurysms of the aorta and one subclavian aneurysm with similar success. Two other patients who suffered from aortitis and dilatation presented, however, no amelioration. They died and the post-mortem examination showed that no coagulation had taken place in the dilated portion of the artery. The operative proceeding was as follows. A solution of 2 gms. of gelatin in 100 of saline solution is made and this is injected under the skin of the thigh into the subcutaneous cellular tissue in a dose of 250 c.c. The injection is renewed at varying intervals of time—every two days to fifteen days. As a rule, 10, 15, or 20 injections are quite enough to obtain a complete cure. The communication of these researches gave rise to a long discussion at the Academy, in which M. Huchard, Professor Hayem and Professor Fournier took part. M. Huchard had employed the method of M. Lancereaux in many cases, one of which was very serious, the pulsation of the aneurysm being very strong. A complete cure was obtained by means of 20 injections, and the sole inconvenience attaching to this treatment was that it was very painful. In a patient suffering from phthisis with constant hemoptysis due to little aneurysms of the kind described by Roemussen, M. Huchard employed the same treatment and succeeded in stopping the hemoptysis. This, however, did not prevent the patient from dying later from pulmonary tuberculosis. Certain precautions have to be preserved in this method of treatment, for a patient, under the care of Boisset, in whom injections had been made on a very small scale lest the blood should coagulate all at once, died very suddenly from embolism. The injections must never be made in the neighborhood of the aneurysmal sac, and still less into the aneurysmal sac itself.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, DECEMBER 3, 1898.

THE ETIOLOGY AND CLASSIFICATION OF PERITONITIS.

In the *Philadelphia Medical Journal* of Nov. 12, 1898, Dr. FLEXNER of Baltimore presents certain facts obtained by the postmortem study of a large number of cases of peritonitis in which careful bacteriologic examinations were made.

Among the earlier studies of the experimental peritonitis, that of GRAWITZ in particular, as well as of others, has clearly defined the conditions that result in the development of peritonitis in animals. GRAWITZ has also shown that these results are nearly allied to the natural conditions found in man. He divided peritonitis into primary and secondary forms; the first accords with the so-called idiopathic or rheumatic peritonitis. In accordance with modern ideas GRAWITZ regards all forms of peritonitis as caused by micro-organisms. Among the favoring conditions he mentions wounds communicating with the abdominal cavity and the accumulation of fluids in such quantities that it can not be absorbed in the natural manner. Pathogenic organisms may be introduced directly, or may be brought by the blood or lymphatic current. Secondary peritonitis is more common, occurring under a number of conditions, bacteria being introduced by contiguity. This group includes the peritonitis of puerperal infection, of intestinal gangrene, and perforation.

FLEXNER finds that many of the cases which GRAWITZ regarded as a primary peritonitis were in reality secondary, indeed only those cases in which chronic renal, cardiac, or hepatic disease pre-existed are convincing examples of the primary form.

TAVEL and LANZ, in their exhaustive study of peritonitis from a bacteriologic standpoint, attempted to answer the question whether peritonitis is or is not a multiple infection, and they conclude that the hematogenous forms are mono-infections, while those forms that proceed directly from the diseased organs are generally poly-infections.

The statistics upon which Dr. FLEXNER's report is based include 106 cases of peritonitis. The bacteriologic examination included was made by means of plate cultures. Several classes can be distinguished. Thus, one might divide them into primary and secondary forms. By secondary peritonitis FLEXNER would understand those following operations upon the peritoneum or the organs which it contains, and those in which the infection of the peritoneum takes place from diseased viscera within it. It is preferable to call all infections of the peritoneum in which the micro-organisms are brought by the blood or lymph current, without the intervention of some diseased organ or part, as primary. The organisms may reach the peritoneum by the blood or lymph current; although it is conceivable that they could pass through the intact intestine, yet convincing proof of this possibility has not yet been furnished.

Of the 106 cases, twelve presented the characteristics of a primary peritonitis; in all of these there were previous chronic diseases. In nine instances there was a single infection, in one instance a multiple infection. The most common organism was the streptococcus.

The secondary forms are far more frequent than the primary, and of these at least two classes can be distinguished, dependent upon the mode of infection. The first class may be designated as exogenous peritonitis; here the microbes enter from without. The condition is really one of wound infection. Of the 106 cases, thirty-four belong to this group. Twenty-five were single, nine multiple, infections, and the bacteria concerned were chiefly the pus microbes, showing a striking similarity with the conditions of ordinary surgical infections, the only difference being that the bacillus coli commune was present in a few cases, being alone in two, combined in five.

The second class of secondary peritonitis FLEXNER terms endogenous; in these the bacteria come partly or wholly from the intestinal tract, and they are therefore chiefly multiple infections. This is the common form of infection; it is represented in this series by sixty cases, in only two of which the bacteriologic examination gave negative results. The single infections were relatively more infrequent in this form, and the micro-organisms found differed widely from those in the exogenous variety. The bacillus coli commune assumes a much more important rôle and the streptococcus is much oftener present. FLEXNER believes that one must concede to the colon bacillus the possibility of producing suppuration.

While the examples of primary or idiopathic peritonitis in this series were really instances of terminal infections in connection with chronic diseases, it is also found that in the twenty-five cases of the exogenous peritonitis twenty-six presented pre-existing more or less chronic diseases of familiar varieties. It therefore becomes necessary to recognize that infection of the normal peritoneum may depend not only upon local but also upon general predisposing causes.

FLEXNER does not see his way clear to definitely establish a group of so-called aseptic or chemic peritonitis, as advocated by BUMM, TAVEL and LANZ, and yet he would not deny its occurrence.

From this extensive material it becomes certain that the primary or idiopathic forms of peritonitis are limited to a rather small number of instances that belong to terminal infections; that a second variety of peritonitis conducts itself very much like surgical infections, and that conditions that predispose to infections in general are in operation here also; a third variety is dependent upon disease in an intraperitoneal organ, which brings pathogenic organisms as well as other substances directly or indirectly into the abdominal cavity which becomes infected from within.

THE MODE OF SPREADING OF BUBONIC PEST.

P. L. SIMOND¹ summarizes a careful research concerning the mode of spreading of bubonic pest in the following important conclusions: The study shows that the pest is spread by two principal factors—the rat and man. Man is the ordinary agent of transport for long distances, which could not be attained by the rat; the rat is the carrier from house to house. It is much more important in this respect than man, and plays the essential rôle in the dissemination of the disease in local epidemics.

When pestiferous rats enter a new district there is usually some delay before the disease appears in epidemic form; the arrival of infected human patients into a new territory is not always followed by epidemics of pest. In order that epidemics may be established there must be a circle of favorable circumstances, among which the preliminary transmission of the virus to rats seems to be the most important. The period of incubation represents the time necessary for the development of the disease among rats.

The gravity of a human epidemic stands in close relation with that of the epidemic among rats. The progress of the disease throughout the city follows the route adopted by the migrating rat. Even when the disease is no longer associated with a great mortality among the rats, it may continue to exist in a benign form, and the so-called sporadic human cases, which manifest themselves after the subsidence of an epidemic, may be attributed to this benign form in the rodent.

A second epidemic of the disease usually manifests itself about twelve months after the appearance of the first, from which it is separated by a longer or shorter period of calm. The reason of this periodicity in the epidemics is not determined. It is undoubtedly connected with the re-establishment of the disease in epidemic form among the rats, and depends in part upon the repopulation of the city involved by these animals. Careful experiments have shown that there is but little danger in the spread of the disease from infected organs or food.

In a certain proportion of cases the point of entry of the microbe is marked by local reaction, which is generally situated in a region where the skin is thin and delicate. When this local reaction, as well as the swelling of the regional lymphatic glands, fails to appear, then it is to be attributed to the great virulence of the micro-organism, and not to a different mode of entrance.

The notion that the transmission of the disease depends upon larger parasites is in accordance with the observations made on rats; a few hours after a rat dies from the disease the fleas abandon the cadaver in order to attach themselves to other animals and to human beings. The points here referred to are strengthened: 1. By the presence of the specific micro-organism in the contents of the intestines of the fleas which have absorbed infected blood. 2. By certain facts in connection with the transmission of the disease from the rat to man and from man to rat. In the last instance it is possible also, that other parasites of the same class as the flea may act as carriers. 3. By the possibility of the transmission of the pest to a healthy rat by cohabitation with a rat covered with pestiferous fleas, whereas cohabitation with a rat sick of the disease but deprived of fleas is constantly harmless.

Finally, it may be stated that the mode of spreading of bubonic pest comprises the transport of the micro-organism by the rat and by man; its transmission from rat to rat, from man to man, from man to rat, and from rat to man by parasites. The prophylactic measures should be directed methodically against each of these three factors; the parasites, man and the rat.

EPILEPSY AND INSANITY.

In the *Philadelphia Medical Journal* of November 19, Dr. J. H. McBRIDE, the well-known alienist, criticises a statement made in an earlier issue by Dr. FREDERICK PETERSON, that less than 10 per cent. of ordinary epileptics become insane. He holds that a large proportion of the chronic epileptics suffer from a more or less marked condition of dementia, and still more frequently from temporary mental perversions, often dangerous, and there is further a special mental condition characteristic of those afflicted with this disorder or symptoms that might, it would seem, be

¹ Annales de l'Institut Pasteur, xii, 1898.

reckoned as insanity, since, as he says, it puts the great majority of them so far out of relation to their environment as to render them incapable of self support. He believes "that, with rare exceptions, habitual epileptics suffer sooner or later from some degree of mental impairment," not always amounting to insanity, but sufficient to incapacitate them for independent self-support, and that a prognosis of mental failure is always justifiable if the fits are not arrested within two or three years. The fits are only indications of a morbid condition that involves the patient's whole mentality and mixes with all he does and is.

These facts are important, if true, and the difference of opinion, or perhaps one should rather say of point of view, of these two eminent specialists renders them the more worthy of consideration. Dr. PETERSON has apparently much the same opinion as his critic as to the disadvantages of the epileptic in the struggle for existence, but he looks upon epilepsy more as a disorder, that, like deafness or blindness or any other disabling defect, often incapacitates its possessor for employment in ordinary occupations without necessarily putting him in the category of the actual insane. A certain degree of mental impairment may even be admitted as a common result of the attacks without rendering it necessary to consider the patient insane, and he probably would admit as much—the difference of the contesting views is therefore somewhat diminished. There is no doubt that habitual epilepsy is dangerous to mental integrity, understanding by the word "habitual" a marked frequency of the attacks, with their very commonly associated temporary mental obscurations or dullness, which of itself in any single fit may be no more marked than that connected with a migraine attack or even an ordinary headache.

This limitation of the meaning of the term, "habitual," however, somewhat alters the case; there is a large proportion of epileptics who would hardly fall under Dr. McBRIDE's definition or conception apparently of the term. There is, first, a considerable number who can hardly be excused from the epileptiform category, in whom only one or two fits may occur in a lifetime—their cerebral instability is so slight that it is only under conditions of special stress that the explosive manifestations can occur. These are perhaps more numerous than is commonly supposed. There is also a second class, in whom the epileptiform manifestations have been confined to special periods of their lives, and while well-marked and frequent at such period, have entirely ceased under proper treatment and removal of the cause. These cases are not numerous, but they exist and have to be considered. One such case was known to the writer, that after having had a number of attacks at one time in his life, afterward rose through his own merits and endeavors to a very high position, one such as few are able to achieve or satisfactorily fill. Such instances are exceptional, it is true, but how far they may be *in posse* amongst

such temporary epileptics no one can say. There is still a third small class of epileptics in whom the fits may be called habitual, though they are not usually very frequent, whose mental failure does not show itself, at least until later in life, and sometimes is never very apparent. While as a class they are seriously handicapped by their affliction, some of them succeed in holding their own in life's competition, and these are they to whom Dr. McBRIDE probably alludes as exceptions so rare as to be hardly worth considering in a discussion of epilepsy. The first two classes are hardly recognized as epileptics at all except by those who know their whole history, and naturally such are few in number.

Taking all these three classes together they must form a considerable percentage of the total number of epileptics. The first two there is reason to believe are more common than is generally realized; they fall for the most part into that great majority which Dr. McBRIDE assumes are probably never seen by specialists. While Dr. PETERSON's estimate of the number that go insane may be too small, it seems equally probable that any very extensive generalizations in the opposite direction are equally liable to be in error.

A word may be said here as to the special mental character credited to epileptics. It is natural to suppose that any such morbid cortical irritability as can produce the phenomena of epilepsy might easily affect the disposition, but it is not a universal fact that all epileptics are abnormal in this respect. Some few of them indeed are very far from it, and the characteristic epileptic character may exist where no genuine symptoms of epilepsy can be discovered. It is hardly a positive criterion of the disease, though in some form or other common enough to be noticeable in perhaps a great majority of pronounced chronic cases.

In conclusion it may be said that it requires a rather broader conception of insanity than is commonly admitted to apply it to epileptics generally, or even to all the chronic cases in their later developments. They are unfortunates, to some extent mentally impaired in a large proportion of cases, but it is as easy to overestimate the frequency of such defect as to underestimate it. In criminal cases this possibility would be very liable to be brought forward, whether rightly or not is not always easy to say, while apart from this contingency their sanity might never be in question.

THE ENGLISH AND AMERICAN ARMIES IN THEIR RECENT CAMPAIGNS.

Without any desire on our part to belittle the sufferings of the United States troops in the recent Spanish War, in the sense that we are desirous of withholding from them the credit for bravery which they deserve, we have felt all along, and have expressed in these pages our belief that much of the

suffering was one of the necessities of the war rather than that due to carelessness or criminal negligence of those who are in authority. This country had been so long blessed with peace, and its people had been for so long unacquainted with the conditions which necessarily arise before, during or after battle, that they had not provided sufficient means for meeting emergencies, and did not at first grasp the impossibility of carrying on an active campaign without the surgical failures which, however much they may be deplored, were to a great extent unavoidable.

Some of our English friends have undertaken to suggest to us that it would be well for American officers to take lessons from their English cousins as to the management of medical and food supplies for an army in the field, and have intimated that much of the suffering of our troops could have been avoided, had our officers been properly equipped in medical details.

Those who have studied the almost simultaneous campaigns of the American troops in Cuba with the British troops in the recent Soudan expedition can not fail to have noticed, notwithstanding the boasted efficiency of the medical arm of the British service, here again the necessities of war resulted in an amount of suffering far in excess of that which was produced by actual wounds. The amount of illness and death which ensued from disease rather than from surgical affections during this British expedition has been large, practically as large as that which has been experienced by our own army, and commanding officers have been unable to provide the wounded with the comforts which humanity would deem desirable. They have seemed to recognize that the object of the war is the speedy conquering of the enemy, and while not ignoring those who have fallen, have continually kept the main object of the expedition in view.

To those who are wont to attack the army administration at Montauk Point or elsewhere, an account which is given by a correspondent in the *British Medical Journal* of November 12, of the recent Soudan expedition, and entitled the "Seamy Side of War," is of interest. In this letter it is shown that in the first advance after the battle of Atbara last spring, indignant protests were made against the insufficient provisions made for the sick and wounded, and not until these protests were made again and again were they heeded in part, and then so late that the relief did not reach the front in time to be of service. Again, we are told that the wounded after this battle were carried so clumsily by native soldiers over rough ground that they frequently slipped and fell, causing torture to the sufferers, and that when English volunteers offered to carry the wounded their services were refused. Again, in the second advance on Omdurman, even greater hardships were suffered. A sudden order to advance, accompanied by one which insisted that hospital tents should be struck

and packed within five minutes, left the surgeons with no place for their sick. Fortunately they found a barge stacked with ammunition, and on this 145 wounded men were hastily carried, with no medical supplies, no food except a few cans of beef extract, and no means of heating this. These wounded men were stumbled over by the Egyptian troops rushing for ammunition in frantic haste, and very shortly additional wounded men had to be squeezed on board until they were "packed like sardines," and the digging of graves being abandoned for lack of time, the dead had to be placed along with the living on the barge to prevent their mutilation, and there they remained, in the words of the correspondent, "emitting effluvia until the following day, when they were buried." Further than this, this barge was left without any military protection, and at any moment every one on board might have been massacred by the enemy. There were only three surgeons to attend to 145 wounded, and operations were done in the sun on piles of ammunition boxes, where the thermometer registered 119 degrees in the shade. We are also told that the Egyptian brigades fared worse than the wounded we have already mentioned.

Either because the English are accustomed to the suffering of their troops and recognize the seriousness of war, or because they are indifferent, which is not likely, their newspapers have not raised the so-called howl of indignation which has characterized the pages of many American newspapers.

THE ARMY MEDICAL DEPARTMENT OF THE FUTURE.

The echoes of our alleged maladministration in military management, and particularly in medico-military matters, come to us from afar off. The *Lahore Civil and Military Gazette* of Oct. 6, 1898, gives credit to the Indian medical service for being one of the few departments which escaped scathing criticism during the campaign in Tirah, on the Northwest frontier. It has been generally admitted that the arrangements for the care of the sick and wounded in that campaign were, as a rule, "most complete and efficient," and that nothing was neglected that could relieve suffering or assist recovery, credit for this being given to the Indian Government, which spared no expense, and to the medical officers themselves for the excellence of their organization and their devotion to duty. The only unfavorable criticisms which appeared were some strictures in the English papers because the stretchers were not provided with awnings nor the field hospitals with the Roentgen-ray apparatus.

After inviting us to look on this picture, the *Gazette* presents us with another of the conditions in Cuba during and after the attack on Santiago. The contrast would have been sufficiently marked even if the second picture had been drawn from official state-

ments instead of from the exaggerations and false reports which appeared as news in the extras of our great dailies during the progress of the war. But the *Lahore Gazette* kindly recognizes the difficulties under which this country labored in expanding an establishment which was practically nothing more than a Federal police force into a military organization for immediate war purposes. It recognizes also from some Indian experiences, what we have learned during the past few months: that the lavish expenditure of money after the occasion has arisen is of little value when compared with the possession of an organization which has been prepared with care for just such an emergency.

This country should have an army competent to cope with the possibilities of the future. The Chairman of the Military Committee of the House of Representatives has been cited as suggesting 100,000 men as the strength of the army required. It is useless to say that we can trust to the manhood of the American people when the occasion requires a resort to arms because we have seen how much unnecessary suffering is ordinarily involved in a sudden muster for war service. With an increase of the Army should be associated an increase in the strength of its medical department, for the argument drawn from experience against a hastily organized fighting force applies with equal strength to a hastily organized medical department for the care of that force.

The medical department of the Army at the present time consists of 192 officers. This number did not suffice for the needs of our Army of less than 40,000 men, scattered as it was at many small posts before the outbreak of the recent war. When war was declared, authority was given to raise the strength of the regular regiments, and there is now or soon will be a strength of about 60,000 men. To meet this increase, the SURGEON-GENERAL, at the close of his annual report, recommended the addition of 88 medical officers to the present force, but he added that this recommendation was based upon present needs, and was irrespective of any increase that might be rendered necessary by legislative action during the coming session of Congress.

The white troops of the British Army, 200,000 strong, have a medical force of about 800 officers, but the contingent on duty in India has often to be assisted by officers of the Indian Medical Service, the corps specially organized for duty in native hospitals and with native regiments. The Army of Spain has a medical force of 900 officers to a strength of 100,000 men, this large force being required, probably, by the prevalence of disease among the troops in the Island of Cuba. Russia has about 400 medical officers of all grades for every 100,000 of its army of nearly 900,000 troops. We may consider therefore that a medical force of at least 450 will be necessary for an army such as that suggested by the Chairman

of the House Military Committee, and this appears to have been the view taken by SURGEON-GENERAL STERNBERG in recommending an addition of 88 officers to his present force of 192 for the needs of the present strength of 60,000 men; 280 for 60,000 is in the proportion of 466 for 100,000.

In forming a corps of 450 medical officers having the same proportion of the various grades as the smaller corps now in the service, there should be one major-general, the surgeon-general; 1 brigadier-general, as assistant surgeon-general; 14 colonels, as deputy surgeons-general; 24 lieutenant-colonels, as chief surgeons; 120 surgeons, majors, and 250 assistant-surgeons, captains and lieutenants. The Chief of the Corps, in view of his responsibilities, which are appreciated by the general public only in trying times like those of the recent war, should have the rank of major-general. The criticism has often been made that the best men will not enter the military service because the prizes are so few, the highest rank attainable being that of brigadier-general, and this reached only by the one man appointed as surgeon-general.

It is hardly to be supposed that any difficulty would be experienced in filling up this enlarged corps with medical men having the proper qualifications. With a larger army, a larger number of positions of relatively high rank as the reward for continued service, and a broader stage of existence opening up in the future, as compared with the dull life of the past at small Western posts, competition for position would no doubt be much greater than heretofore. Besides, the taste of military life obtained during the past months by volunteer medical officers would also have its influence in filling up the medical positions of an enlarged army. After the Civil War, little effort was made by volunteer surgeons to enter the regular army. Many of them had, no doubt, got enough of war service during the long-continued struggle, but the main cause was the want of vacancies. Retrenchment and reduction of the military establishment followed the Civil War, instead of the expansion which seems needful to meet the present requirements of the country.

An enlargement of the powers of the medical department is of as great importance to its efficiency as the number and grade of its personnel. The Spanish War demonstrated the inability of medical officers, however willing and energetic, to accomplish their object when dependent on others for essentials. If medical officers are to be held responsible for the sick and wounded, they should be given powers commensurate with their responsibility. Any bill for the enlargement and improvement of the medical corps should provide for its independence of the quartermaster's department. It should have command of its ambulances, hospital tents, wagons and of all the equipment necessary for the transportation and care of the sick and wounded of the army.

We feel sure from the energy displayed at Santiago in trying to overcome the difficulties caused by inefficient quartermaster's management, that were medical officers their own quartermasters the *material* of the field hospitals would always be on hand where it was required unless interdicted for imperative military reasons by the commanding general.

CORRESPONDENCE.

The Jugglery of Statistics.

WASHINGTON, D.C., Nov. 21, 1898.

To the Editor:—I had hoped that after Deputy Surgeon-General Smart's reply to an absurd editorial on the "Jugglery of Statistics," which appeared in the *JOURNAL* of October 29, no one would seriously quote the mortality rates of the Civil and Spanish Wars, adduced by the *Philadelphia Medical Journal* of October 15, and yet the writer of the editorial on the "Caribbean Climate in its Medico-Hygienic Relations" (*JOURNAL*, p. 1249) committed this error.

I cannot refrain, therefore, from referring the writer of the editorial to the article above referred to, and if still unconvinced he may profit by Dr. Smart's letter on the "Vital Statistics of the War," which appeared in the *JOURNAL* of November 19.

Respectfully yours,

GEORGE M. KOBER, M.D.

The Commission Evil.

ST. PAUL, MINN., Nov. 28, 1898.

To the Editor:—In your issue dated November 26 Dr. Robert T. Morris writes to inquire whether your editorial condemning the purchase and sale of cases is founded upon a knowledge of specific instances of this sort.

I can not answer for the *JOURNAL*, but can assure Dr. Morris that I know of at least a half dozen surgeons and physicians of excellent standing in the profession who in a subterranean way carry on this traffic.

As an internalist I can not say that I have ever felt such competition, nor indeed do I know of any stricely medical man who pays commissions, but I have personal knowledge of a score of surgical cases in which fees have been paid or demanded.

It has given me great pleasure to know that my protest against this indefensible practice, contained in a letter to the *N. Y. Medical Journal* of October 29, has resulted in bringing this matter into a prominence which must end in its complete annihilation.

Yours very truly,

CHAS. LYMAN GREENE, M.D.

A Pair of Large Twins.

FORT COLLINS, COLO., Nov. 22, 1898.

To the Editor:—On Nov. 7, 1898, I was called to attend Mrs. C. in confinement. Found the abdomen enormously distended, and from the size and irregular shape I diagnosed probable multiple pregnancy. In five hours I delivered her of a girl baby weighing ten and three-quarter pounds, and four hours later of a boy weighing ten pounds. Both children are strong and healthy. The girl was delivered without assistance, but the boy had to be delivered with forceps. Both were the left occipito-anterior presentation. There was but slight laceration, and aside from some rise in the temperature of the mother, during the first week, everything proceeded normally. The placenta were separate and small. There is no history of twins in the family so far as I can learn. The patient is 20 years of age, married one year and a primipara. Fraternally,

Respectfully yours,

W. A. KICKLAND, M.D.

BOOK NOTICES.

A Manual of the Practice of Medicine. By FREDERICK TAYLOR, M.D., F.R.C.P. Fifth edition. Pp. 1002. London: J. & A. Churchill, 1898; from P. Blakiston's Sons and Co. Philadelphia. Price \$4.00.

This well-known work is a short yet complete work on the practice of medicine and in the preparation of this fifth edition it has been very carefully revised and some sections rewritten, and notice of many diseases recently recognized or omitted from former editions have been added. Among the former are the introduction of diseases of the nervous system, diseases of the blood and the subject of aphasia and ringworm. In the latter are glandular fever, diver's paralysis, erythromelalgia, angioneurotic edema, hypertrophic pulmonary osteo-arthritis, and tubercle of the skin. A special section is devoted to diseases of the mediastinum, and filarial diseases and hemo-globinuria have been transferred to diseases of the lymphatic system and of the blood respectively.

As only a little over eight years have elapsed since the first edition of this work was issued, the fact that five editions have been called for in the eight years attributes to the value and popularity of the work, beyond the powers to review or to increase or diminish the elements of its popularity, as will be seen by a perusal of the work. Its comprehensiveness consists in the fact that no essential detail is omitted, and no superfluous words or phrases included, all excellent characteristics, as our readers will undoubtedly agree.

Traumatic Separation of the Epiphysals. By JOHN POLAND, F.R.C.S. 337 illustrations and skiagrams. Pp. 926. London: Smith, Elder & Co., 1898; New York, G. P. Putman's Sons; Chicago, A. C. McClurg & Co. Price \$18.

The literature of this subject is quite extensive, although widely scattered, and the author has brought together and summarized the records heretofore published. The following is the table of contents: Chapter 1, Historic; 2, Anatomy; 3, Etiology; 4, Frequency of the Various Separations; 5, Experiments in Pathologic Anatomy, and their Histologic Anatomy; 6, Pathologic Anatomy; 7, Symptoms; 8, Prognosis and Results; 9, Treatment. The remainder of the work is devoted to separation of the epiphyses of the upper extremity, separation of the epiphyses of the clavicle, separation of the epiphyses of the scapula, separation of the upper epiphysis of the humerus, separation of the lower end of the humerus before puberty, separation of the lower epiphysis of the humerus in youth, separation of the internal epicondyle of the humerus, separation of the external epicondyle, etc., separation of the upper epiphysis of the radius, thumb, metacarpal bones, phalanges; then follow articles on the separation of the epiphyses of the lower extremities, the pelvic bones, the femur, bones of the leg and of the foot. The work concludes with articles on separation of the epiphyses of the vertebræ and ribs, and an appendix.

There are 299 illustrations in the text, besides a vast number of skiagrams, showing the development of the bones.

Few books have appeared in recent times of more value to the advanced surgeon than this, and the superb dress in which the publishers have presented it makes it a pleasure to peruse. We can not too strongly commend this work, and congratulate the profession on the valuable addition to surgical literature which is here presented.

Clinical Lectures on Mental Diseases. By THOMAS S. CLOUSTON, M.D., Lecturer on Mental Diseases in the University of Edinburgh. New (5th) edition. Crown 8vo, 750 pages, with 19 full-page colored plates. Philadelphia and New York: Lea Brothers & Co. Cloth, \$4.25, net.

As the study of mental diseases has become compulsory on all medical students, good text-books, arranged in a manner which leads to an easy understanding of the subject, are abso-

lutely necessary. These qualifications are possessed by Clouston's work, which is suitable alike for the general physician and the specialist. The advances that have been made in psychiatry in the two years that have elapsed since the presentation of the last edition have been incorporated. There is one thing that always gives a charm to Clouston's works, i. e., his honesty, modesty, and entire candor. It is evident from a perusal of the pages of this edition that Clouston will continue to remain a constant favorite.

A Pocket Medical Dictionary giving the Pronunciation and Definition of the Principal Words used in Medicine and the Collateral Sciences, including very complete tables of the arteries, muscles, nerves, bacteria, bacilli and micrococci, spirilli and thermometric scales and a dose list of drugs and their preparation, in both the English and metric system of weights and measures. By GEORGE M. GOULD, A.M., M.D. A new edition, entirely rewritten and enlarged, including over 21,000 words. Pp. 530, exclusive of dose table. Philadelphia: P. Blakiston's Sons and Co., 1898. Price, \$1.

The confidence of the public in Dr. Gould as a dictionary-maker is such that they are largely ordered in advance, and different editions follow one another with such rapidity that it is difficult to keep track of them. The present dictionary will be found extremely useful.

A Quarterly of Clinical Lectures, Etc. Edited by JUDSON DE LAND, M.D.; J. MITCHELL BRUCE, M.D.; DAVID W. FINLAY, M.D. Volume III, Eighth series, 1898. Philadelphia: J. B. Lippincott Company, 1898.

This volume brings the clinic to the library of the practitioner, and many of the clinics are so literal that without a very great stretch of imagination one can almost see the patient being described by the clinician. The practitioner who wishes to keep in touch with the latest advances in the practice of medicine, surgery and the specialties can do so no easier than by keeping up with the clinics as set forth in this admirable series.

Hartley-Auvard System of Obstetrics. Revised by JOHN D. HARTLEY. Third (1898) edition, 436 pages, 543 illustrations, 1898. New York: Flint & Co., 104 Fulton St. Cloth \$4, leather or half morocco \$5.

In this work the author plunges in *medias res* without preface or introduction, and as far as possible diagrams are introduced to illustrate the author's views. In the whole art of obstetrics he has brought it as near as possible to the mechanical basis. The teachings are correct, and all unnecessary and extended discussions are omitted. Practitioners and students will find this work of great value.

A Text-Book of Pathology. By ALFRED STENGEL, M.D. 372 Illustrations. Pp. 848. Philadelphia: W. B. Saunders, 1898; W. T. Keener, 52 Randolph Street, Chicago Agent. Price, cloth, \$4; half morocco, \$5 net.

In this book the author has presented the subject of pathology from the point of view of the clinical pathologist. Prominence is given to pathologic physiology; controversial matters and discussion of methods have been omitted as far as possible. The work is divided into two parts, of which the first is on General Pathology, the chapters of which are as follows: 1. Etiology of Disease. 2. Disorders of Nutrition and Metabolism. 3. Disturbance of the Circulation of the Blood. 4. Retrogressive Process. 5. Inflammation and Regeneration. 6. Progressive Tissue Changes. 7. Bacteria and Diseases due to Bacteria. 8. Animal Parasites and Diseases Caused by Them. Part 2, Special Pathology, is arranged as follows: Chapter 1. Diseases of the Blood. 2. Diseases of the Lymphatic Tissues. 3. Diseases of the Circulatory System. 4. Diseases of the Respiratory System. 5. Diseases of the Gastro-intestinal Tract. 6. Diseases of the Ductless Glands. 7. Diseases of the Urinary Organs. 8. Diseases of the Reproductive Organs. 9. Diseases of the Bones. 10. Diseases of the Joints. 11. Diseases of the Voluntary Muscles. 12. Diseases of the Brain and its Membranes. 13. Diseases of the Spinal

Cord and its Membranes. 14. Diseases of the Peripheral Nervous System.

While not as exhaustive as many works on the subject, it may be said that it fairly covers the ground, and so far as the ground is covered the work is well done and has been brought quite down to date.

We are glad to see that weights and measures used in the book are according to the decimal system.

The illustrations are excellent, and students as well as practitioners will find the work of great value.

NECROLOGY.

D. A. MCTAVISH, M.D., died at West Bay City, Mich., November 17. The Doctor was born in Glencoe, Ont., in 1855, was graduated from Toronto University in 1881, was a licentiate of the Royal College of Physicians and Surgeons of Edinburgh, Scotland, and a member of the Michigan State Medical Society.

CHARLES MASSEY HAMMETT, M.D., formerly health officer and coroner of the District of Columbia, died in Washington, November 22, of chronic interstitial nephritis, aged 63 years.

JAMES S. KELLY, M.D., Archbald, Pa., November 16, aged 27 years.—William R. Straw, M.D., Vinita, Ind. Terr., drowned November 21.—A. E. Sullard, M.D., Franklin, N. Y., November 19, aged 79 years.—Herman Voeller, M.D., Sacramento, Cal., November 14, aged 65 years.—J. T. Webster, M.D., Emporia, Kan., November 12, aged 44 years.—A. E. Willard, M.D., Friendship, N. Y., November 20, aged 67 years.

PUBLIC HEALTH.

Etiology of Dysentery.—A careful study of an epidemic of dysentery affecting 1121 persons in a town of 24,300 inhabitants, has resulted in the conclusions that the meteoric influences, the drinking water, contagion and food, can only be considered as predisposing or secondary causes. Also that the distinct groupings in the quarters where the ground water is the closest to the surface, indicate the predominant rôle to be attributed to the water and the subsoil in the etiology of the affection. There the disease had birth, and thence it was propagated. The writer concludes, therefore, that besides the hydric origin of dysentery and of typhoid fever, we must also ascribe it in certain cases to telluric action.—*Bulletin de l'Acad. de Méd.*, October 31.

Prevention of Insanity Among Adolescents.—A superintendent of a large hospital for the insane, near New York City, states in his annual report that "societies for the prevention of cruelty to children would do well to branch out into the work of prevention of insanity in childhood by insisting on more outdoor physical exercise, and less intellectual over-work, until the body has been developed to a sturdy, healthy frame, checking the emotions and grading study according to the age and physical condition of the child. Physical deterioration, if not actual pathologic conditions, exist in seven-tenths of our cases and act as exciting causes for mental disturbance." He has observed, what is plainly evident, that a larger proportion than formerly of the patients admitted to insane hospitals have the insanity supervening upon a very imperfect constitution, which has been either inherited or, more frequently, acquired through an unwise early management leading to physical deterioration.—*Charities Review*, November.

Laboratory Contagion.—The quarantine physician at Suez comments on the dangers of infection from experimental laboratories, regretting that they are not invariably isolated with as much care as a contagious-diseases ward in a hospital. "I know," he continues, "of a laboratory devoted to the study

of epidemic diseases, which is located on the ground floor of a government building. The corridor leading to it is the single corridor for the use of all the employees and their families, who live in the upper stories. The space containing the cages of the animals involved in the experiments, is only separated from the common yard where the children play by a lattice-work. The least negligence may lead to the most serious consequences." Landouzy observes: "The most insignificant case of animal plague, escaping from a defectively guarded laboratory, threatens to become, more or less readily and rapidly, the occasion of an epidemic that may break out so far from its starting-point as to be practically untraceable."—*Presse Méd.*, November 5.

Unsanitary Management of Cemeteries.—It seems that those who die in Cuba are destined to secure the peace and quiet of sepulture only so long as they have paid for the niche in which they are destined to be deposited. "Rest in peace" depends upon the affection and willingness of the dead person's friends to pay another's rent in advance. When the year expires, unless the yearly rental is forthcoming, the coffin is unceremoniously taken out and dumped on a convenient field without the sacred *campo*. The walls of these niches become masses of germ-laden masonry, alternately warmed by the tropic sunshine and kept moist by tropic dews. In other words, they are most favorable culture-beds, and containing, as they do, the foul germs of yellow fever, become, when disturbed, sources of wide-spread infection. The disinterring of the dead is not allowed in Jamaica. Four years ago in one of the West India Islands belonging to Great Britain, part of an old cemetery was dug up which contained the graves of many yellow fever victims. Yellow fever had been absent from the island for years, but immediately after this it appeared and made many victims.—*Red Cross Notes*.

Transmission of Contagious Diseases by Insects.—P. R. Joly (*Thèse de Bordeaux*), in a monograph on this subject, quotes instances of malignant pustule, Egyptian ophthalmia and Delhi boil conveyed by flies. He has also found that the legs of flies may be covered by staphylococci and many other forms of bacteria. Tubercle is particularly liable to be disseminated by flies. They come in contact with sputa and other media, whereby the tubercle bacilli discharged from the body of the patient becomes ingested, and then alight on food and deposit the tubercle bacilli, and thus easily contaminate milk, meat and other substances. The author quotes Yersin as having noticed that the bodies of dead flies collected in his laboratory often contained numbers of the plague bacillus. The influence of various insects, more particularly the mosquitoes, in carrying the *flaria sanguinis* is well known. The mosquito has also been suspected as the agent in the conveyance of malaria.—*Medical Review of Reviews*, October.

Tuberculosis and Food.—At the recent meeting of the French Association for the Advancement of Science the section of hygiene, at the suggestion of Professor Nicholas, passed a resolution pointing out that the conveyance of tuberculosis by inhalation is only one of the modes of infection, and that a larger part of the diffusion of the disease is played by contagion through the alimentary canal, as proved experimentally and clinically, urging the necessity of taking adequate measures to insure the sterilization and harmlessness of articles of food. In this resolution the opinion was expressed that it is desirable in addition to take measures to suppress, or at least diminish the causes of weakening of the constitution, which make it fall an easy prey to the disease—overstrain, confined air, overcrowding and unhealthiness of dwellings. In every dwelling a sufficient cubic space should be allowed in proportion to the number of the inmates, and all apartments must be freely ventilated and exposed to the sunlight; it is also necessary that low-built houses should be furnished with large courts to insure

perfect aëration. In this respect the English cottage system represents the ideal which should be aimed at. The section further urged that the widest possible publicity should be given to the modern doctrines as to the contagious nature of tuberculosis and its prophylaxis; this should be done by means of public lectures, and also by the moral influence which medical men can exercise in their own sphere. The curability of the disease should also be insisted upon.—*Nature*.

Chronic Enterocolitis.—It is important, says Dr. McKee in the *Philadelphia Polyclinic*, to recognize the fact that most cases of this disease in infancy and childhood originate in chronic milk infection. Not infrequently another infection may run coincidentally with the infection, and possibly adds its depressing influence. In some cases, the malarial organism has been demonstrated. When the etiology is clear, the treatment becomes quite plain: 1. Withdraw milk from the diet, and do not return to it until the case is well on the road to convalescence; then resume milk cautiously. 2. The affection must be treated locally, and best by enterocolitis. Silver nitrate (1 to 2000 or 4000) is used twice or thrice daily until the stools begin to lose their vile odor (salt solution is used to neutralize each injection of silver). In the last convalescent stage, tannic acid injections, as recommended by Dr. E. Holt, are invaluable. Dr. Wiley of the Children's Clinic has had excellent results with the latter injections, and Dr. McKee can heartily indorse the treatment. 3. Intestinal antiseptics are of signal use, as they are in all cases of milk infection; salol and benzo-naphthol have given best results in the Children's Clinic. 4. Astringents by the mouth are best withheld, for the kidneys are likely to suffer in any case. 5. Ingenuity may be well-nigh exhausted in feeding the youngster, for we have a chronic process with which to deal and nutrition must be maintained. 6. Hygienic details will demand attention for several months, and tonics must be employed over a corresponding period of time.

Morbific Influences of Burial Grounds.—The dwelling places of the dead have, from time immemorial, been the source of dread to civic aggregations, but chiefly within our own memory have they been the occasion of preventive legislation, on the score of their being prejudicial to public health. Until the discovery of pathogenic bacteria, this was not attributed to exhalations from the decomposing bodies of those interred, and to the pollution of the ground-water, which subsequently found its way into wells from which it was drawn for potable purposes. Since the discovery and identification of disease-producing micro-organisms, the tendency of sanitarians has been to regard these as the infecting element. While there have been numerous instances in which cemeteries have apparently been responsible for the spread of disease, still there have always been those who have claimed that the proof has been insufficient, and that other causes have been instrumental in producing the results attributed to the cemeteries. The Imperial Board of Health of Germany has instituted an investigation in this important matter, the result of which is exceedingly reassuring to those who are compelled to live in the neighborhood of places of interment. In the experiments conducted under the Board's direction, dead hogs and dogs, in which had been placed tuberculous material, anthrax and typhoid germs, were buried in boxes in the ground and at various intervals of time thereafter both the ground-water and the soil were examined to determine the presence or absence of living germs. Ninety-six days was the longest time that the typhoid bacillus was found alive, while the cholera spirillum lived but twenty-eight; the tubercle bacillus less than 125, and the bacillus of tetanus less than 361 days. Anthrax was the most persistent, being found capable of communicating infection after one year. It must be borne in mind that these results were obtained by examination of the material inside the boxes, or in immediate proximity thereto. With the exception of the anthrax there were no germs found away from the places in which the bodies were buried.—*Brooklyn Medical Journal*, November.

NEW INSTRUMENTS.

A PRACTICAL OZONE INHALER.

BY W. SCHEPPEGRELL, A.M., M.D.
NEW ORLEANS, LA.

In the October issue of the *JOURNAL* there is described "A Scientific Ozone Inhaler," by Dr. Cyrus Edson of New York City. Ozone is a useful remedial agent, which has been used to advantage in many pathologic conditions, but the apparatus described is not a conservative method of generating this gas, as but a small portion of electric energy is utilized for this purpose. It compares with the *scientific* method of generating ozone very much as the heating capacity of a single steam-pipe does with that of a modern steam radiator.

The most economical and practical method of generating ozone is by means of the ozonizer first described by Siemens, and which I have used in the treatment of diseases of the nose, throat and ear for some years, and described in the *Journal of Laryngology*, London, July, 1897.

This apparatus consists of a kind of Leyden jar, which is prepared by coating the interior of a glass tube with tin foil and passing over this a second wider tube, also coated with tin foil on its outer surface. Between the two tubes a current of air or oxygen is passed which becomes electrified by induction,

the inner and outer coatings of tin foil respectively being connected with the terminals of a strong induction coil or static machine. By this mean it is possible to convert 10 or 15 per cent. of oxygen passed through the tube into ozone, which is more than twenty times the efficacy of the ordinary disruptive discharge, which is the method used in Dr. Edson's apparatus.

In the description of Dr. Edson's apparatus, it is specified that a static machine should be used to generate the electricity. An induction coil with a capacity of a six-inch spark is equally effective and can be used without correcting the hygrometric conditions of the atmosphere, as is usually necessary with the static machine. The method by means of which the ozone is applied in diseases of the maxillary sinuses is shown in the accompanying illustration.

A NEW LIGHT-SCREEN.

BY JAMES THORINGTON, M. D.
PHILADELPHIA, PA.

This is made by attaching an iris diaphragm to an asbestos chimney. The amount of light passing through the opening

in the diaphragm is controlled by an ivory-tipped lever at the left-hand side. An index at the periphery records the diameter of the opening in millimeters, from one to thirty.

When using the Maddox rod for muscle testing, the light streak can be made thread-like, or very broad, by regulating the size of the opening in the diaphragm.

While this screen may be of use in otology, laryngology, and in general ophthalmology, yet it is primarily for retinoscopy: simplicity and great convenience in controlling the amount of light being it points of merit.

To Messrs. Wall & Ochs I am indebted for their careful workmanship and skill in making a diaphragm the leaves of which are not affected by the heat.

120 South Eighteenth Street.

SOCIETY NEWS.

Southern Illinois Medical Association.—This association will hold its next meeting at Carbondale, Ill., the second Tuesday in May, 1899.

The American Medico-Psychological Association, to hold its next annual session in New York, May 23 to 26, 1899, has for officers: Henry M. Hurd, Baltimore, Md., president; Henry A. Gilman, Mt. Pleasant, Iowa, vice-president; C. Bell Burr, Flint, Mich., secretary and treasurer.

Rome (N. Y.) Medical Society.—At the first regular meeting, held October 11, the following officers were elected: John F. Fitzgerald, president; H. D. White, vice president; Thos. P. Scully, secretary; Jas. H. Whaley, treasurer. The society meets the second and last Tuesday of each month.

American Academy of Railway Surgeons.—This society, which is to meet in October, 1899, at Omaha, Neb., elected officers as follows: William W. Grant, Denver, Col., president; John P. Pritchard, Manitowoc, Wis., and John P. Lord, Omaha, Neb., vice-presidents; Thomas P. Lacey, Council Bluffs, Iowa, secretary; C. P. Kibler, Corry, Pa., treasurer; Frederic J. Hodges, Ashland, Wis., editor.

Des Moines (Iowa) Pstholological Society.—This society held its first annual meeting November 8, and elected the following officers for the ensuing year: E. D. Dorr, president; G. E. Currie, vice-president; M. F. Patterson, secretary; D. W. Smouse, treasurer. M. N. Voldeng was offered the presidency for another year, but refused to accept, believing a change of presidents should be made each year. The society was organized a year ago, and has held thirty profitable meetings, with good prospects for the future.

San Francisco Society of Eye, Ear, Nose and Throat Surgeons.—The regular meeting for November was held the 17th, at the office of Dr. Geo. H. Powers. Dr. Powers presented a case of convergent squint in which the fixation point of the left eye was very excentric, and in which the vision of that eye had gone down to $\frac{2}{1000}$. He was very loath to operate, deeming the chance of obtaining a betterment of the deformity very small. The patient insisting, however, he did tenotomy on the inner and on the superior tendons. Strange to say, there resulted almost immediate improvement, not only as to the squint, but the fixation point became much more central, though not yet quite at the exact center, and the vision improved to $\frac{2}{100}$, and is yet improving. From a cosmetic standpoint alone, the operation seemed to have been very satisfactory. Dr. Barkan presented a case of arrested development of the left ear in which only a small portion of the external ear was present, and in which the presence or absence of the inner ear, or of the bony meatus, could not be ascertained. The case had first called at the Cooper College Clinic, where the examination record stated that whisper could be heard in the left ear at a distance of eight inches, and a loud whisper at a distance of six feet. When examined by Dr. Barkan at the meeting of the society, it could not be definitely decided that the whisper could be heard at all on that side, and the result from examination with various tuning-forks was also rather negative, though there was some appearance of hearing a high pitched tuning-fork on the mastoid of the affected side. No operative measure had been thought of or was intended; the case was presented simply for its rarity. Dr. Barkan also presented a case of high myopia which he had recently operated upon with gratifying results. He stated that it was the ninth case of the sort on which he had operated, and was the most unpromising of them all. When seen, the patient, a woman of some 45 years, had vision of fingers at two feet, in the right eye, and six feet in the left eye. The apparent refractive error was -20 in the right and -18 in the left; with -19 right, vision was fingers at six feet, and with -20 in the left, vision was fingers

at nine feet. There were numerous floating opacities and retinal changes in both eyes; some atrophic and pigmented spots. The woman could read Snellen 5, at 4 cm. from the eyes. On account of the retinal changes and the extremely bad condition of vision, operation was not advised; but the patient was unremitting in urging that the operation be attempted, stating that she was going blind quite rapidly and could be no worse without any eyes than she was with them in the condition in which they then were. Discussion was made, and nine days later extraction of the lens. All the lens matter was not at the time extracted, but it subsequently cleared up nicely by absorption, leaving a good clear pupil, with but one small iritic adhesion. There was some trouble with the eye following the operation, but the inflammatory condition gradually subsided. The vision, after operation, was fingers at from ten to twelve feet; with a -2 spheric lens, vision was $\frac{1}{200}$; she could read Snellen 1 with a spheric lens of $+9$, or a cylinder of $+2$, axis 180° . The Doctor accentuated the fact that we should not consider all the cases of high myopia in which there are retinal changes, apparently grave, as hopeless and beyond the pale of operation. He had performed the operation nine times, and all were gratifying results. Dr. Powers presented two cases of sympathetic ophthalmia in old men, after a lapse of from thirty to fifty years, and in both of which the lost eye had not received a foreign body, but had been destroyed by a simple traumatism. In both cases the sympathetic trouble came on very slowly and was not at first recognized, for the reason that there was no pain or involvement of the destroyed eye. The true condition was eventually suspected and the atrophied eye removed, when the ophthalmia subsided at once. In both the eyes which he had removed he found a bony plate, but no evidence whatever of any inflammatory trouble.

MISCELLANY.

Differentiation of Bacilli.—Kashida, working under the direction of Professor Ogata in the Hygienic Institute of Tokio University, has confirmed the observation of Petrúschky and Wurtz, that the bacillus coli, when grown in whey, gives rise to an acid reaction by the fermentation of lactose, whereas the bacillus typhosus does not. He finds that with the bacillus coli the acid reaction is only temporary, being succeeded by an alkaline. The latter is so strong that the colonies in plate-cultures on litmus-milk-sugar-agar, previously reddened by the addition of rosolic acid, acquired an intensely blue color. No such production of ammonia could be obtained with the bacillus typhosus. He recommends as a culture-medium a 1.5 per cent. bouillon agar, to which are to be added 2 per cent. of milk-sugar, of urea, and 3 per cent. tincture of litmus.—*Centralb. f. Bakt.*

Hardly an Accepted Fact.—Mr. Henry Guy Carleton, at the dinner of the New York State Medical Association at the Manhattan Hotel, New York city, October 19, asserted that stammering was due to the presence of the comma bacillus. In his own case he averred that the malady itself was not congenital, but appeared when he began to talk. According to his microscopic slides he said the microbe was abundantly in evidence after every syllable. He freely gave his discovery to the profession without any design of profit from patent or trademark.

Appendicular Liver.—Professor Dieulafoy asserts that any appendicitis, even the most benign, may become the cause of a hepatic infection manifested by the rapid formation of multiple abscesses, by the dozens and hundreds, scattered throughout the liver, transforming it into a sort of purulent sponge, to which he gives the name of appendicular liver. The disproportion is most striking between the tiny closed cavity of the appendix where the toxi-infection is elaborated, and the great organ affected by it, in which the microbes, endowed with incredible virulence, may determine such extensive lesions in the course of a few weeks or even days. The hepatic complications of appendicitis appear abruptly, sometimes in the midst of convalescence, commencing with a terrible attack of fever, followed by others, accompanied by pain in the organ

and its rapid enlargement, icterus, and frequently vomiting and diarrhea. Appendicular hepatic infection is always fatal. The only treatment is prophylactic, which consists in operating during the first days, without allowing this complication on the part of the liver time to develop.—*Semaine Méd.*, November 9.

Chronic Suppurations of the Tonsils.—The surface of the tonsils may appear perfectly normal, and yet there may be unsuspected abscesses below. A case was recently described at the Berlin Society of Internal Medicine, in which, after repeated inflammations of the tonsils, dyspnea and edema of the glottis suddenly appeared, requiring tracheotomy. At the necropsy a purulent infiltration of the latero- and retropharyngeal tissue was found, extending to the mediastinum, with pus also in the pleural sacs. The tonsils were the seat of several abscesses. The infection may have extended locally from them, but there was probably also direct absorption of pathogenic germs from the repeated inflammations. The conclusions were drawn that every angina must be subjected to rigorous treatment and perfect antisepsis of the mouth and throat should be maintained.—*Deutsche Med. Woch.*

Chorea Minor from Foreign Body in the Ear.—*Memorabilien* (October 21) relates a case of chorea minor, in a girl of 13 years, that has lasted two years, when a physician found a piece of lead from a screw pencil in her ear, resting against the tympanum. The foreign body had never caused any disturbances in the ear, but its removal was followed by complete recovery from the chorea.

Contemporaneous Uterine and Extra-Uterine Pregnancy.—Kiriak reports a case terminating in abortion and the extraction of a fetus from the posterior cul-de-sac. On account of temperature he removed the placenta and uterus later by laparotomy. The patient recovered.—*French Cong. of Gyn. and Obstet.*

Strychnin-like Alkaloid in a Corpse.—During the examination of a partially decomposed body, Mecke met with an alkaloid which chemically might easily be mistaken for strychnin, but which physiologically did not injure frogs, had scarcely a bitter taste, and did not produce the least effect on animals when injected subcutaneously. With picric acid it gave a yellow crystalline precipitate, becoming violet on treatment with sulphuric acid and bichromate. Bichromate alone produced a yellow crystalline precipitate, changing to blue with sulphuric acid. Bichromate and acid together yielded a blue, afterward a reddish, color. Ferrocyanid gave a yellow precipitate, turned violet by acid. On the other hand, chlorin-water gave (as with strychnin) a milky liquid, but when after evaporation the residue was treated with ammonia, it became a dirty green. It dissolved in sulphuric acid to a yellowish liquid, afterward changing to cherry and rose-red. Frohde's reagents dissolved it, giving a dull violet color, which finally became olive, and then green. The substance is not the same as that discovered under similar conditions by Anthon in 1887.—*Phar. Zeit.*

Anesthetics in Scandinavian Countries.—The report presented at the Northern Surgical Congress held at Helsingfors in August, embraced 25,305 anesthetics with chloroform, resulting in 15 deaths, asphyxia in 303 cases, and vomiting in 1789. With ether, 2926; no deaths; asphyxia in 25; vomiting in 309. With chloroform and ether in 3616 anesthetics there were no deaths, but asphyxia in 82, and vomiting in 461. With 794 with ethyl bromid, there were no deaths; asphyxia in 3 and vomiting in 39. The secondary effects noted were: with chloroform 18 cases of death, 54 of heart failure, 46 of pulmonary troubles, 153 of albuminuria, 49 of somnolency, 20 of icterus, and 4338 of vomiting. With ether: 3 deaths, 4 cases of heart failure; 28, pulmonary troubles; 46, albuminuria; no icterus; 585, vomiting. With chloroform-ether, 8 deaths; 13 cases of heart failure; 13, pulmonary troubles; 17, albuminuria; 10, somnolency; 1, icterus; 731, vomiting. No secondary effects

were observed with ethyl bromid except vomiting in 7 cases. The total number of all kinds of anesthesia reported was for the last three years, 32,641. The mortality was therefore: with chloroform, one death in 1687 anesthetics, and one death in 1406 from the after-effects. No deaths from the other narcotics directly, but indirectly one in 975 with ether; one in 452 with chloroform-ether, and none directly or indirectly from the 794 anesthetics with ethyl bromid. The anesthetics are classified and discussed with much detail in the volume of the *Nordiskt Med. Ark.* devoted to the Congress.

The World's Food-Supply.—At the opening of the British Association for the Advancement of Science, President Crookes, in his inaugural address, broached the theory that beyond 1931 the wheat supply would not keep pace with the needs of the population. He said that nitrate of soda was not inexhaustible, but that nitrogen in the atmosphere was unlimited, and suggested the burning of nitrogen in the air by a powerful electric current. Niagara Falls, according to his view, could thus produce fixed nitrogen at a cost of £5 (\$25) per ton, thereby making a yield of wheat equal to thirty bushels an acre. As a saving clause he admitted that the exuberant tropic food stuffs might supply the threatened deficiency of wheat for the benefit of future generations.

Eaters of Human Flesh.—According to a French writer, whose statements appear in the *Medical Presse*, 20 per cent. of all cannibals eat the dead for the purpose of glorifying them; 19 per cent. eat great warriors in order that they may inherit their courage, and eat dead children with a view of renewing their youth; 10 per cent. their near relatives from religious motives, either in connection with initiatory rites or to glorify deities, and about 5 per cent. feast for hatred, expecting in this way to avenge themselves upon their enemies. Those who devour human flesh because of famine are reckoned as 18 per cent. There remain only 24 per cent. who eat such flesh because they prefer it.—*N. Y. Tribune.*

Porcelain Enamel Casts for Filling Teeth.—A new method of filling teeth has been suggested by the author of a communication received by the Paris Académie de Méd. in competition for a prize. He has used it for two years and in 203 decayed teeth, with most satisfactory results in every case. He first prepares the tooth for the filling in the usual aseptic manner, and then takes an impression of the cavity with a thin sheet of platinum which forms a hollow mold. The enamel paste is poured into this mold and a casting made in one piece, identic with the cavity in the tooth. The cavity is then filled with cement; the enamel casting is inserted and carefully fitted into place. The normal color and transparency of the tooth is retained; an important esthetic improvement over gold fillings; the enamel never wears out; the cement is protected on all sides from the air and saliva, does not undergo any alteration and the amount remaining in the crevices is so minute that there is no irritation of the nerves of the tooth, which is one of the drawbacks to cement fillings. He uses porcelain enamel with a melting point of 1200 degrees C., and makes the small casting on the spot and at the moment needed, with a small English steel furnace lined with fire-brick, which attains a temperature of 1600 to 1800 degrees. He is not content with the application of this method to dentistry alone, but suggests its application to surgical operations in which there are bone defects to be remedied. He thinks that a porcelain enamel casting made on the spot, aseptic, never corroding, never wearing out, would answer the purpose perfectly in cases of necrosis, osteomyelitis, etc., although he has no practical experience with it.—*Bulletin*, October 31:

Delirium from Sodium Salicylate.—Two cases of acute delirium lasting about forty-eight hours, with no fever, after the ingestion of twelve grams of the salicylate in a day and a half, have been recently reported. *Presse Méd.*, November 5.

Trained Workers for the Feeble-minded.—The school for the feeble-minded at Faribault, Minn., has recently celebrated the first graduating exercises of its training school for attendants and nurses. This training school is a new departure in work for the feeble-minded, and its results give satisfaction to the institution and State officials. The course extends over two years, and the pupil attendants take about forty lectures a year. The subjects covered are elementary physiology, hygiene, practical sanitation, and the elements of chemistry; but the chief element in the training is not the knowledge obtained from books. The most important factor is the attendant's relation toward the children—or the purpose of the school is to develop the motherly relation toward the children. The spirit of tenderness and devotion of these foster-mothers is magnified, and they must become proficient in correcting the diet, habits, exercise and cleanliness of their wards.—*Charities' Review*, November.

Hospitals.

The new hospital of the University of Colorado, at Boulder, Colo., was dedicated November 19. It has been erected at a cost of \$15,000, the building, a handsome three-story brick structure, occupying a site adjacent to the campus and near the medical laboratories, on the high bluff overlooking the river and city of Boulder.—Early in November the McDonald Building of the Presbyterian Hospital, Cincinnati, was dedicated. The building was erected at a cost of \$60,000, the entire expense being met by Mr. and Mrs. McDonald, whose contributions to the Hospital and the Laura Memorial College (Medical School for Women) amount to \$130,000.

A Proposed Sanitarium.—The Knights of Pythias have on hand a fund of \$12,000 as a nucleus of the proposed fund of \$500,000 for a sanitarium at Hot Springs, Ark. This may require five years for realization. The members of the organization in the United States are to be assessed one dollar each.

Re-establishment of Regimental Hospitals.—The War Department has recently authorized the establishment of regimental hospitals in the newly formed camps in Alabama, Georgia and South Carolina. According to a formal order the purpose of the regimental hospital in field service is to furnish protection and care to the sick of the command while on a march or in the field, or to those temporarily sick while in camp of instruction. It is an emergency hospital in the one case and a detention hospital in the other, but is not intended for the treatment of the very ill, who in the event of a move would prove to be an incumbrance to the regiment. When cases are found to be serious in nature they should be promptly transferred to brigade or division hospital, except where regiments are isolated, in which event the bed capacity may be increased as necessary, all of the sick being cared for and transfers made to general hospitals when ordered by proper authority. Four hospital tents are allowed to each regiment, two as wards, one as dispensary and storeroom, and one as mess room. The personnel is to consist of three hospital stewards, one acting steward and six privates of the hospital corps as nurses and orderlies, with one private for each ambulance and wagon. Two four-horse wagons are allowed to each hospital. On November 15 a circular from the Surgeon-General's Office announced the outfitting allowance of instruments, disinfectants, furniture, bedding, clothing and miscellaneous articles for these small hospitals. When a regiment is so located that its sick can not be sent to a brigade, division or general hospital the regimental hospital will be expanded to meet the requirements of the case.

X-Ray Apparatus for Military Posts.—According to the *Press and Circular*, November 9, the British War Office, recognizing the advantages of the X-ray in military surgery, has issued a large number of outfits to the home and foreign stations under its charge.

Montauk Not Criticised.—A clipping before us with this cap-

tion, says: "Army men are following with pained interest the details which reach this country of the sickness and suffering at Montauk and the other military camps. I am bound to say that I myself neither hear nor read of any criticism unfavorable to our government in this matter. Discussing the question with a military officer of high rank, he quietly said that any man of sufficient age could tell such stories of Crimean hospital mismanagement and disease as would hardly be believed in these days. The mere memories, ancient as they are, curb any temptation to criticise the misfortunes of others. Yet there is no need to go so far back, for in the late Afriki campaign many of the arrangements for the sick and wounded were as primitive and hopelessly inadequate as if the clock had been put back forty years. On the other hand, the surgical department of the Soudan expedition is almost perfection, as well it might be, when Kitchener has been seeing to it all for many thoughtful months."

Naval Medical Incident.—One of the gunners of Admiral Schley's fleet is said to have lost his reason as a result of the naval battle of July 3, with Cervera's squadron. He is now in St. Elizabeth's Insane Asylum, Washington, D. C., undergoing treatment. The patient's trouble began with concussion of the brain, caused by the detonation of the heavy guns fired during the fight. This is regarded as an unusual case. The report set forth that eight of the ten casualties upon the American ships in the battle of Santiago were ruptures of the ear drums, caused by the terrific cannonading. One of the cases was that of Lieutenant Harrison of the Oregon, who stuck his head out of a turret just as a thirteen-inch rifle was fired. The noise and shock of the explosion lacerated the drum of both ears, and for a time he was totally deaf. Under the careful treatment of the naval surgeons he is gradually recovering his hearing and will in all probability be as well as ever in a few more months. All the other men who were similarly affected have been cured and have returned to their ships for duty. During the fight at Manila there is no record of any of Admiral Dewey's men receiving injuries of this sort. The explanation of this is simple. The gunners on battleships are accustomed to plug their ears with cotton to protect them before firing begins, but at Santiago there was no chance for precautions of this kind. The men were on deck for inspection at the time the enemy was discovered issuing from the harbor, and they simply rushed to their guns and began blazing away without thought of cotton or anything else. At Manila the men were all prepared for the fight, every precaution having been taken to prevent injury to ear drums, etc.

Army Medical Conditions on the Pacific Coast.—Reports from the Division Hospital of the Eighth Army Corps, the command on the Pacific coast from which the strength of the Philippine expedition is kept up, are satisfactory as showing a steady improvement in the medical conditions. The hospital consists of two new brick buildings with hospital and conical wall tents, the whole having a capacity of 320 beds. The tent accommodations are utilized for contagious cases which can not be isolated properly in the permanent buildings, and for the stronger convalescents who are not proper subjects for furlough or discharge. In August, 177 cases of measles were treated—a considerable reduction from July—due in part to prompt isolation and thorough disinfection, and in part to the exhaustion of the susceptibility of the commands. In September, one of the wards for this disease was discontinued. Formaldehyde was used for the disinfection of clothing in these cases. Fifty-nine cases of pneumonia—13 fatal—were reported in August, and 31, with 3 deaths, in September, quite a number of these being sequent to measles. Sixty-four cases of mumps in August and 70 in September were complicated with orchitis in an unusual proportion. Six cases of malignant scarlet fever were admitted in August, in two of which

death resulted from complications. Vigorous sanitary precautions were taken in these cases. All clothing was burned in preference to trusting to disinfection. No case occurred in September. During this month there were, however, 4 cases—2 fatal—of diphtheria. Eight cases—3 fatal—of cerebrospinal meningitis were treated in August, and 9 cases—2 fatal—in September. In August there were 97 cases of typhoid fever, with 6 deaths, and in September 162 cases, with 16 deaths. Hemorrhage from the intestines was the determining cause of death in the fatal cases. Many of the cases were exceedingly mild. Great care was exercised to have typhoid discharges properly and immediately disinfected and promptly disposed of. This division hospital is now competent to take care of all the sick of the command, those formerly treated in the city hospitals having been furloughed or withdrawn. Thirty trained nurses are now on duty at the hospital, which is under the charge of chief-surgeon W. S. H. Matthews, U. S. V.

Colleges.

Harvard is to receive \$10,000 from the estate of the late Edward Austin of Boston, for the laboratory of the medical school.—On November 25, the Indiana Medical School, a department of the University of Indianapolis, was destroyed by fire, caused by a defective furnace. The loss will amount to \$40,000; insurance \$35,000.

Societies.

The following recent meetings are noted:

Arkansas.—Little Rock Medical Society, November 12.

California.—California Northern District Medical Society, Sacramento, November 15.

Illinois.—Champaign County Medical Society, Champaign, November 17; Chicago Medical Society, November 23; Southern Illinois Medical Association, Cairo, November 18.

Indiana.—Tippecanoe County Medical Society, Lafayette, November 21.

Iowa.—Des Moines County Medical Society, Burlington, November 16.

Maine.—Maine Academy of Medicine, Portland, November 14.

Maryland.—Baltimore County Medical Association, Baltimore, November 23; Medical and Chirurgical Faculty of Maryland, Frederick, November 16 and 17; University of Maryland Medical Society, Baltimore, November 17.

New York.—Albany County Medical Society, Albany, November 16; N. Y. State Association of Railway Surgeons, Manhattan, November 17; Oswego County Medical Association, Oswego, November 16.

Ohio.—Columbus Academy of Medicine, November 21; Union Medical Association of Northwestern Ohio; Akron, November 15.

Tennessee.—Middle Tenn. Medical Association, Nashville, November 17.

Utah.—Salt Lake Medical Society, Salt Lake City, November 14.

Request for Information.—The catalogue committee of the Alumni Society of the Medical Department of the University of Pennsylvania desires a short biography of every medical alumnus, and this appeal is made for aid of graduates of the University in such compilation. The following is the form of biography desired: 1, name in full; 2, father's name and mother's maiden name; 3, date and place of birth; 4, State matriculated from; 5, date of matriculation; 6, date of graduation; 7, title of thesis; 8, place of practice and present address; 9, college attended; 10, titles; 11, publications made and positions held; 12, if ever in the United States service, in what capacity and when and how long; 13, if married give maiden name of wife; 14, children's names, if any; 15, if dead, give date and place. Several thousand biographies have already been catalogued. The Committee especially desires the histories of the graduates between the years 1781 and 1790, names of whom are found in the "Proceedings of the Alumni Society" for 1898, and already widely distributed. Data in reference to medical alumni serving in the "French and Indian," the "Revolutionary," the "War of 1812," the "Mexican," the "Civil War," and the recent Cuban War, it is

hoped will soon be ready for collation. Assistance in this work is earnestly solicited. R. G. CURTIN, M.D., Chairman; F. SAVARY PEARCE, M.D., Secretary.

San Francisco.

COOPER MEDICAL COLLEGE.—The long proposed change in the time of the commencement of the college year of Cooper Medical College has finally become a fact. The next regular course will commence on January 3, and close Aug. 12, 1899. The next following course will commence Oct. 1, 1899, and close May 31, 1900. Thereafter the regular course will commence on August 15 and continue for eight months. This change has been made in order to conform to the general custom of medical colleges throughout the country, of having the regular course in winter instead of the summer months. The change is a very welcome one to both faculty and students.

FACULTY CHANGES.—At the last regular meeting of the faculty of Cooper Medical College Drs. Stanley Stillman and Emmet Rixford were elected professors of surgery, and Dr. William Fitch Cheney was elected professor of the principles and practice of medicine. Drs. Stillman and Rixford have for some time been assistants in the chair of surgery and their promotion was expected. Dr. Cheney has done remarkably good work in the chair of children's diseases for several years past, and has been rapidly making a name for himself not alone within the State of California.

A NEW MEDICAL COLLEGE.—The medical department of the University of California, at the opening exercises of their new home south of Golden Gate Park, San Francisco, October 22, appointed a Committee of Ways and Means to extend their influence. Correspondence with various institutions regarding plans and costs is one of the methods. The new building is well provided with laboratories, but eminent men in various lines of work are necessary to fill the chairs, and supporting salaries are to be given so that entire devotion to their work may be assured.

London.

MEMBRANOUS RHINITIS.—A most suggestive report upon membranous rhinitis was presented before the late Medical and Chirurgical Society by Dr. Lambert Lack. In spite of the mild form and chronic six or eight weeks' course of the disease, the Klebs-Loeffler bacillus was found to be present in every one of the thirty-three cases examined. Although mild, the disease was highly infectious and the bacilli proved fully virulent to animals, to produce abundance of toxins and to grow luxuriantly upon culture media. Hence the problem at once arises, why the toxic symptoms of diphtheria were not produced in at least some of these cases? Dr. Lack himself was inclined to attribute the immunity to the presence of other organisms associated with the Klebs-Loeffler, while in the discussion that followed, both Dr. Allan Macfadyen and Dr. Goodall regarded the resistance of the tissues at the point of invasion as the chief factor. This would seem the more probable explanation, in view of the high bactericidal power of the nasal mucus, and also of the frequency with which the diphtheria bacillus is found in healthy noses without giving rise to any toxic symptoms whatever. Indisputable as is the connection between diphtheria and the Klebs-Loeffler bacillus, evidence is rapidly accumulating to show that its mere presence in the fauces or nose is far from being the only factor, and that the resisting powers of the individual, or of the different regions or tissues, plays an even greater part. Possibly the dangerousness of that old remnant—the tonsil—as a point of entry for infection, may be as great in this disease as we are beginning to regard it in scarlet fever and in tubercle.

CLINICAL LECTURES.—The unique clinical lectures of Mr. Jonathan Hutchinson, held every Wednesday afternoon at his private clinical museum, are becoming one of the best known and attended "medical fixtures" of the London winter session. Among the cases presented at the last meeting was a most typical one of Paget's disease, a raw, red, oozing patch, slightly elevated at its serpiginous edges, of about the size of the palm of the hand, upon the left breast of an old woman of 72. It begins upon the nipple and runs an extremely mild and chronic course, lasting for years and seldom involving the lymphatic

glands or even the deeper layers of the skin itself—"a granulating surface which never heals," as the lecturer tersely described it. Another case was a striking illustration of the fact that the wages of sin and the results of economy are sometimes hardly distinguishable from each other. A man of 40, with an indurated sore upon his upper lip, huge swollen cervical glands, a hoarse voice, a perforated palette, and a superb crop of huge flat-topped condylomata between the nates and in both groins, all from buying in a moment of parsimony a second-hand pipe. The sore upon the lip appeared only ten days after the first use of the pipe and the classic procession followed. The condylomata in the groins were so large, flat and bathed in pus as to give an almost typical picture of the tubercles of Yaws, much of which the lecturer believes to be neglected syphilis. The case was a good illustration of the virulence of syphilis from an extra genital chancre, as the usually tertiary perichondritis of the larynx had occurred before the primary sore had healed or the buboes disappeared and the whole train of symptoms had developed in four months' time.

Craig Colony Prize.—The president of the board of managers of Craig Colony offers a prize of \$100 for the best contribution to the pathology and treatment of epilepsy, originality being the main condition. The prize is open to universal competition, but all manuscripts must be submitted in English. All papers will be passed upon by a committee to consist of three members of the New York Neurological Society, and the award will be made at the annual meeting of the board of managers of Craig Colony, Oct. 10, 1899. Each essay must be sealed in an envelope containing the name and address of the author, and bearing on the outside the motto or device which is inscribed upon the essay. The successful essay becomes the property of the Craig Colony, for publication in its "Annual Medical Report." Manuscripts should be sent to Dr. Frederick Peterson, 4 West Fiftieth Street, New York City, on or before Sept. 1, 1899.—*The Craig Colony Press.*

Gleanings.—Ballaban's new cyclochrome for rapid changes of colors is proving a desirable substitute for the inexact perimenter.—Loessen has secured exceptionally well-shaped nostrils and tip in rhinoplastics, with a rubber frame the same color as the skin, made by an artificial tooth maker. Israel forms the tip with a piece of the tibia.—Successful resection of the cardia in dogs followed only by ten days of vomiting; probably still easier of performance on man in case of carcinoma of the cardia, diagnosed early by palpation.—Péron reports experiments in which the effusion in spontaneously healing tuberculous pleuritis was found to possess an immunizing power in tuberculous infection in dogs. He queries whether withdrawal of the effusion by puncture is not directly injurious to the patient (*Klin. Therap. Woch.*, November 6).—Case of leukemia reported, evidently due to internal injuries received in a crowd, in which the spleen had been injured.—Case of retinitis in Bright's disease simulating a malignant tumor. Nothing was found after extirpation but hyaline degeneration and glaucomatous phenomena with decollement of the retina. First instance on record of this lesion in Bright's disease (*Wratsch*, August 8).

THE PUBLIC SERVICE.

Movements of Army Medical Officers.—To duty in the camps: To the Commanding General First Army Corps at Americus, Ga.: Major Frank J. Ives, brigade surgeon, as chief surgeon Second Brigade, Second Division, relieving Major Frank Bruso from this assignment; also Acting Asst.-Surgeons F. Arthur Zeller and Herbert J. Harris. To the Second Army Corps: Major Lewis Balch, brigade surgeon, for assignment to the Second Brigade, Second Division, subsequently ordered to the First Division, First Army Corps, as sanitary inspector with the first troops embarking for Cienfuegos, Cuba. To the Seventh Army Corps: Major James E. Pilcher, brigade surgeon, for assignment. To the Sixteenth U. S. Infantry: Acting Asst.-Surgeon B. F. Van Meter, at Fort Thomas, Ky. To the Second U. S. Artillery for duty with its batteries, at Savannah, Ga.: Capt. Geo. J. Newgarden, Lieut. Clarence J. Manly from Columbus Barracks, Ohio, and Lieut. R. P. Strong from the Fourth Army Corps, at Huntsville, Ala., all assistant-surgeons, U. S. Army; also Acting Asst.-Surgeon Ricardo Gaston, from Fort Crook, Neb.

To Havana, Cuba: Lieut.-Col. R. M. O'Reilly, chief surgeon Vols., on completion of his present duty in Washington, D. C.; Major John J. Archinard, brigade surgeon, from duty at Santiago, and Acting Asst.-Surgeon Joaquin L. Duenas.

To Santiago, Cuba: Major Valery Hayard, surgeon, U. S. Army, returning to station; Lieut. Ira A. Shimer, assistant-surgeon, U. S. Army, from U. S. General Hospital, Fort Myer, Va., and Acting Asst.-Surgeon Rupert Norton, on the expiration of his present leave. Acting Asst.-Surgeons Samuel P. Cottrell and James G. McKay.

To Manila, Philippine Islands: Acting Asst.-Surgeon M. A. Robert, from York, Pa.

To Honolulu, Hawaiian Islands: Major M. W. Wood, surgeon, U. S. Army, from Boise Barracks, Idaho.

To Hospital Ships: Lieut. P. C. Fautleroy, assistant-surgeon, U. S. Army, from the Josiah Simpson General Hospital to the *Missouri*, and

Capt. Alex. N. Stark, assistant-surgeon, U. S. Army, from the *Missouri* to command the *Bay State*.

To the Josiah Simpson General Hospital, Fort Monroe, Va.: Acting Asst.-Surgeons R. B. Westredge, John A. Metzgar, H. A. Barnhardt, Ed. W. Pinkham, John S. Fogg, Ralph L. Taylor and Roy A. Wilson.

To the care of soldiers in civil hospitals: Major David C. Peyton, brigade surgeon, Vols., to assume supervision of the sick in the following hospitals in Pennsylvania: Chester County Hospital, West Chester; St. Joseph's Hospital and Lancaster General Hospital, Lancaster; Reading Hospital and St. Joseph's Hospital, Reading; Good Samaritan Hospital and Lebanon Hospital, Lebanon; Harrisburg Hospital and St. Clare Infirmary, Harrisburg; York Hospital, York; Charity Hospital, Norristown; Pottstown Hospital, Pottstown; Pottsville Hospital, Pottsville; and Columbia Hospital, Columbia. In Baltimore, Md., Major Lewis W. Crampton, surgeon, U. S. Army. In Providence, R. I., Acting Asst.-Surgeon H. P. Abbott.

To duty with the Fourth Army Corps, Huntsville, Ala., Major Rafael Echeverria, brigade surgeon, Vols.

To military posts: Major E. C. Carter, brigade surgeon, Vols., to Washington, D. C., as attending surgeon, on completion of his duties at the Sternberg and Leiter General Hospitals. Capt. Geo. J. Newgarden, assistant-surgeon, U. S. Army, to Fort Adams, R. I. At Fort Sam Houston, Texas, Capt. Chas. Lynch, assistant-surgeon U. S. A. At Fort Logan H. Roots, Ark., Lieut. Samuel M. Waterhouse, assistant-surgeon U. S. A. At Fort Sill, Okla., Major Marlborough C. Wyeth, surgeon U. S. A., from duty as medical supply officer at Camp Meade, Pa. At Fort Wayne, Mich., Capt. Merritt W. Ireland, assistant-surgeon U. S. A., from duty at Santiago and Montauk Point. At Fort Hamilton, N. Y., Major A. H. Appel, surgeon U. S. A., his orders to Fort Grant, Ariz., having been rescinded. To Sullivan's Island, S. C., Acting Asst.-Surgeon F. A. Holliday, from Washington, D. C.

Leaves of absence granted: Capt. Francis A. Winter, assistant-surgeon U. S. A., and the following acting assistant surgeons: Rupert Norton, E. A. Southall, Frank Roberts and Randall R. Hunter.

Sick leaves granted or extended: Major W. H. Wakeman, brigade surgeon Vols.; F. D. Bain, surgeon Second Ohio Infantry; Major Hiram B. Thompson, Surgeon Third Connecticut Infantry; Major Murray T. Clements, surgeon Fifth Massachusetts Infantry; Major Chas. T. Polard, surgeon Fifth U. S. Vol. Infantry; Captains Henry C. Fisher and Jefferson D. Poindexter, assistant-surgeons U. S. Army; Captain Ellis Duncan, assistant-surgeon First Kentucky Infantry, and Acting Asst.-Surgeons John Horni, Elbert E. Persons, Roy A. Wilson, H. B. Emerson and Milton D. Norris.

Honorably discharged: Majors Royce D. Fry, Francis T. Metcalf, Frank Bruso, Oscar Le Seure and Lewis Balch, brigade surgeons; and Capt. Herbert W. Cardwell, assistant-surgeon Second Oregon Infantry, to accept commission as chief surgeon U. S. Volunteers.

Resigned: Capt. Chas. S. Jordan, assistant surgeon First North Carolina Infantry, and Lieut. John M. Martin, assistant-surgeon Fifteenth Pennsylvania Infantry.

Contracts annulled: Acting Asst.-Surgeons Benjamin F. Wooding and Lewis M. Walker, Josiah Simpson General Hospital; Roger B. Ames, Huntsville, Ala.; Jesse Ramsburgh, Plattsburgh Barracks, N. Y., and Acting Asst.-Surgeon J. A. Dunwoody, of Cripple Creek, Colo.

Retired: Major Norton Strong, U. S. Army.

CHANGE OF ADDRESS.

Becker, B. A., from Dubuque, Iowa, to Silver Lake, Wis.
Barslow, J. M., from 221 S. 6th St. to Merriam Block, Council Bluffs, Iowa.

Budwig, M., from 150 2d Ave. to 226 E. 114th St., New York City.
Bernheim, A., from Paducah, Ky., to 1940 N. 6th St., Philadelphia, Pa.
Burkholder, J. F., from 354 E. 55th St. to Reliance Bldg., Chicago.
Durham, C. O., from 302 to 602½ S. 11th St., Indianapolis, Ind.
Fanning, G. J., from Harlem, Mont., to New Orleans, La.
Gage, M. E., from Sparta, Wis., to Valdosta, Ga.
Gillie, C. W., from Doon to 4th and Jefferson Sts., Waterloo, Iowa.
Herbeck, J. H., from Boulder, Colo., to Cuernavaca, Mexico.
Herr, A. W., from Battle Creek, Mich., to 1926 Wabash Ave., Chicago.
Klebs, E., from Stewart Bldg. to 419 Indiana Ave., Chicago.
Lemone, R. S., from 1623 to 3526 Washington Ave., St. Louis, Mo.
Prieoleau, W. H., from Charleston, S. C., to 242 W. 43d St., New York City.
Peavy, J. F., from Atmore, Ala., to Asheville, N. C.
Raynor, W. J., from Denver to Fort Logan, Colo.
Rowe, S. B., from 925 Bayard to 3437 Bell Ave., St. Louis, Mo.
Smith, J. W., from Cumberland, Va., to Rowlesburg, W. Va.
Schuster, B. L., from Milwaukee, Wis., to Am. Circus 2, Berlin, Germany.
Siegelstein, L. E., from 299 to 333 Woodland Ave., Cleveland, Ohio.
Terry, M. C., from 628 to 718½ Adams St., Chicago.
Wright, W. J., from Lansing to Gregory, Mich.
Williams, C. C., from 1396 Winfield St. to 716 Westlake Ave., Los Angeles, Cal.

LETTERS RECEIVED.

Arnold, E. F. G., New York City; American Therapeutic Co., New York City.
Bell, Samuel, Newberry, Mich.

The Journal of the American Medical Association

VOL. XXXI.

CHICAGO, ILLINOIS, DECEMBER 10, 1898.

No. 24.

ADDRESS.

CHAIRMAN'S ADDRESS.

Presented to the Section on Physiology and Dietetics, at the
Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY RANDELL HUNT, M.D.

SHREVEPORT, LA.

Welcome, gentlemen of the AMERICAN MEDICAL ASSOCIATION! Welcome to this Section, assigned as a place of instruction and enjoyment, for the communication of knowledge and the circulation of thought! And specially welcome to this hall set apart for the science of physiology and dietetics.

The chief end of all medicine is to secure to humanity the blessings of health, and this can only be attained by the scientific education of the physician. It is accordingly the paramount duty of all medical associations to foster and promote higher education.

The chief cause of disease is ignorance; the foundation of health is knowledge, for knowledge is the parent of science and her natural and only safe guardian. Impressed with these truths, physicians are advocating thorough education—education involving comprehensive knowledge of the laws of Nature and philosophy—a knowledge indispensable to thorough appreciation of the dignity of the science and art of healing.

The Supreme Being, when he made the universe and created matter and all classes of beings, animate or inanimate, gave to every class its conditions and appropriate functions. Order, proportion and fitness pervade the whole. The world around us and the world within us are ruled by immutable law. We see, we feel, we regard with wonder and admiration the rule. Our very spirits, that seem so spiritual, so subtle, so free, are subject to it. The material world, the heavenly bodies, the earth, and the different elements of the universe have their laws, beasts have their laws, man his laws. The celestial as well as the terrestrial world knows, and, without swerving, observes and obeys its prescribed course.

This truth is illustrated in the grandest and most sublime of the works in nature, and in the least and lowliest—in the laws that regulate the planetary motions, the range of planets, suns, and adamantine spheres wheeling unshaken through the void immense, and in those which form a drop of water. The vastness and multitude of the celestial bodies, the laws which astronomy in its higher branches discloses and applies, the distances which it spans, the periods which it estimates, impart a sublimity which lifts the soul to the heavens. The law of gravitation is the most universal law known to us. It prevails apparently through all space, but does not prevail alone, for its function is to balance other forces, of which we

only know that these again are needed to balance the force of gravitation.

Each force, if left to itself would be destructive of the universe, for the force of gravitation prevents the centrifugal force from flinging the planets into space, while centrifugal force prevents gravitation from dashing them against the sun. The orbits, therefore, of the planets, with all that depends upon them, are determined by the adjustment between the law of gravitation and other laws that are less known, so as to produce and maintain the existing solar system. This grand example of the principle of adjustment gives no idea of the extent to which the principle is required and is adopted in the works of nature.

The revolution of the seasons, seed-time and harvest, depend on the law of gravitation, in this sense, that if the law were disturbed, or if it were inconstant, they would be disturbed and inconstant also. But the seasons equally depend on a multitude of other laws—laws of heat, laws of light, laws relating to fluids, to solids, and to gases, and to magnetic attractions and repulsions—each of which laws is invariable in itself, but each of which would produce utter confusion if it were allowed to operate alone, or if it were not balanced against others in the right proportion. The seasons depend not only on the facts and laws which astronomy reveals, but on other sets of laws revealed by other sciences, such as chemistry, electricity and geology.

Chemistry abounds with illustrations of the law of forces in mutual adjustment, for the forces that determine chemic combinations all work under sharp definite rules. Some of the laws which regulate this combination are wonderful and beautiful, of great exactness, having invariable relations to numbers and proportion. Each elementary substance has its own combining proportions with other elements, so that, except in these proportions, no chemic union can take place at all. And when chemic union does take place, the compounds which result have different proportions employed. The same elements combined in one proportion are sometimes a nutritious food or a grateful stimulant, soothing and sustaining the powers of life, while, combining in another proportion, they may be a deadly poison, paralyzing the heart and carrying agony along every nerve and fiber of the animal frame.

The whole progress of plants from the seed to the root, and thence from the root to the seed again, the method of animal nutrition, digestion, and all other branches of vital economy, are not left to chance, but are performed in a wondrous manner, and guided by unerring rules laid down by the great Creator. Thus it is through the whole of nature; laws everywhere—laws in themselves invariable, but so worked and so adjusted as to produce effects of inexhaustible variety, by being pitched against each other and made to hold each other in restraint. Not a tree, not a flower, not a blade of grass, not even a drop of water, not one of

the countless varieties of form in clouds, but is ruled by law, by forces which are free only within the bounds of natural law:

All are but parts of one stupendous whole,
Whose body Nature is, and God the soul;
That changed through all, and yet in all the same,
Great in the earth as in the ethereal frame,
Warm in the sun, refreshes in the breeze,
Glow in the stars, and blossoms in the trees;
Lives through all life, extends through all extent,
Spreads undivided, operates unspent;
To him no high, no low, no great, no small;
He fills, he bounds, connects, and equals all.

Advancing knowledge of physical law has been constantly accompanied with advancing power over the physical world, and has enabled us to do a thousand things which a few centuries ago would have been considered supernatural. Physiology shows the structure of man, the superiority of the human organization, its various functions, and all that is connected with the animal life of man, over those of the rest of the animate creation. And even here in man, the highest type of God's creative genius, natural law is paramount and immutable. Disease is a deviation from health; a deviation consisting in the alteration of function, property or structure of some tissue or organ, owing in most part to a disregard or ignorance of natural physiologic, hygienic and dietetic law. Disease is thus an abnormal performance of those processes that constitute life, a knowledge of which must necessarily precede the practice of medicine.

ORIGINAL ARTICLES.

THE MILK-SUPPLY OF CITIES: CAN IT BE IMPROVED?

Presented to the Section on State Medicine, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY HENRY O. MARCY, A.M., M.D., LL.D.
BOSTON, MASS.

Sanitation has made rapid strides in the protection of the public from a great variety of dangers, and more and more each year are emphasized the interdependence and correlation of the entire body politic. This is especially true in urban life, and many of the relations which were thought to be purely personal and individualistic are now accepted as common, and are to be most satisfactorily dealt with under general supervision and control. The development of the water-supply and sewerage of cities is an illustration of common needs, more and more demanding a union of public interests, supervised by men of the highest talent, specially trained for this service.

Modern science has pointed out many dangers to which the individual is exposed, and it is with special satisfaction that we refer to the labors of this generation in having defined the causation and limitation of a large class of the diseases to which the human race is liable.

Ever present—from birth to death—is the daily need of supplying the wants of the system with materials from which the vital economy extracts the products necessary to repair the waste and rebuild the organism. During the first year of life this is furnished almost exclusively by the maternal milk, or that from animals, and nearly every individual incorporates milk daily into his supply of food.

In nursing, this complex animal product is con-

veyed directly, without contamination, into the stomach, and therefore becomes easy of digestion and assimilation. We have learned to know that milk is an excellent culture-medium for certain forms of bacteria, and that, because of these and other contaminations, it rapidly undergoes changes which are deleterious to the animal organism, and may be the means of diffusing disease in a variety of forms. In a very brief period after its production it becomes entirely unfit for food.

It is generally accepted that by far the larger single cause of mortality during the first year of life is owing to improper feeding—"bottle-fed infants." Dr. S. W. Abbott, Secretary of the State Board of Health of Massachusetts, in a recent paper entitled "The Saving of Children," says: "I have carefully examined the list of diseases in which an increased death-rate has occurred in Massachusetts, and have no hesitation in stating that boards of health in our large cities will find a fruitful field of work in the study of the question of infant mortality, its causes and the prevention of its excessive prevalence. Another reason for encouragement in this special direction is the fact that many lives saved in infancy are saved for a long and useful life, and are in fact so much added wealth to the community at large."

Dr. Schlossman says: "The death of every child constitutes a definite loss of national wealth. On the other hand, energy expended in saving the lives of the aged from the inroads of disease at the later periods of life only saves this class at a period when they are most likely to be a burden to the community."

Dr. Abbott quotes statistics to show that the death-rate of children under one year of age, per one thousand and births, in Ireland from 1884-1888, was only 94, which is the lowest figure in foreign countries. In England it was 144, in France 165, in Massachusetts varying from 150 to over 200, and in the large cities often exceeding this latter percentage. It is generally conceded that this abnormally high percentage of death-rate is largely due to improper feeding.

How shall this, perhaps the most important of all our food supplies, be economically and safely furnished the public? is the subject to which I invite your attention and in its solution solicit your earnest co-operation. Manifestly, the first subdivision of the subject will be the source of the product—the animal furnishing the milk. Since man has almost exclusively selected the cow for this purpose, we will limit our inquiry to this animal. The improvement of the breeds of cattle is manifestly important, although the time at my disposal will not permit the discussion of this branch of the subject. It must be accepted that the animal furnishing the milk should be maintained in a state of health. This necessitates a proper feeding, healthy surroundings, a good water-supply, a certain amount of daily exercise out of doors, and protection from exposure and cold. It might be assumed that the interest which the owner of a dairy has in his herd, from an economic standpoint, would be a satisfactory guarantee in the securing of the public protection. Unfortunately, however, this is not true, and from a narrowly selfish standpoint the owner of the cow oftentimes considers her only as a machine from which to realize the largest possible product. Since this is estimated and sold as quantity rather than quality, the attention is often directed to the supplying of food products, accepted by the owners to be in

a certain degree deleterious to the health of the animal, but recognized as stimulating to the milk secretion, as well as not seldom cheapening the keeping expense of the animal. Articles generally known as more especially damaging are the distillery products and certain imperfect forms of ensilage, more or less universally contaminated by various fungoid growths known as moulds, etc.

The owner's self-interest is also oftentimes, if not commonly, brought into collision with the public good in the employment of too little and a low grade of service in the care of the animals. This is at present very generally recognized in careless and dirty methods of milking, especially during the period of housing made necessary by northern winters. The filth incorporated in the milk by the ordinary methods of stable-milking is a source of serious damage to the product, and if observed by the average consumer would be stigmatized as disgustingly filthy.

These interests of the milk-producer, resulting from ignorance, carelessness and worse, so plainly conflict with those of the consumer, that the public has a right to demand that all the sources of milk-supply production shall be constantly kept under public inspection and control, viz., that a healthy animal furnishes a clean and healthy product for public consumption.

The second subdivision of the subject is: Having a good product furnished by the dairy, how can it most safely and economically be distributed to the consumer? By general consensus of opinion the clean milk should be cooled as rapidly as possible, since bacterial decomposition goes on slowly at low temperatures, and immediately put up in sterile receptacles. Since tin is in common use, boiling water and steam furnish safe and economic methods. When glass is selected, and for many reasons it is much to be preferred, after washing, sterilization is easily effected by dry heat. Once put up for the public use, the product should be exposed as little as possible in reaching the consumer. This is the great objection to the large can.

Some years since, as chairman of a committee having public inspection of the milk-supply of the city of Boston, we found the greatest contamination resulted from the dirty methods practiced by small dealers, in recanning in a filthy stable in pints and quarts for family use. This was often labeled as one cow's milk, and especially recommended for the use of children. The cheap corner grocery is another source of milk defilement, which oftentimes is kept in dirty surroundings, even living rooms, and sold in small quantities for the use of neighbors.

Until within a comparatively brief period milk-inspection, although demanded by law, has been a perfunctory and superficial affair. It was deemed of chief importance to prevent dilution and the incorporation of foreign substances. Dilution with pure water may be the least damaging to the consumer, although he does not obtain the full value of his purchase money, while the addition of coloring matter to give the milk a rich, creamy appearance, is not especially injurious.

The real dangers with which the public has to contend lie in the contaminations already referred to. Besides these there is the lack of economy necessitated by the rapid distribution of a product which deteriorates every hour after its production so rapidly that by the third day it becomes a waste product.

We admit that the problem is by no means easy of solution, and that in the aggregate it is of enormous magnitude; and yet modern science seems to be extraordinarily lacking in furnishing better means for supplying a universal want. Other food products are cared for much more satisfactorily, so that the consumer has his table supplied economically and safely from the markets of the world. We cease to marvel at the fresh salmon daily distributed, which comes to us in good condition from Alaska. We find poultry of the autumn, fattened upon the western cornfields, in good preservation during the months that follow; even the mutton from New South Wales vieing in the English market in quality with the Southdowns of the previous day's killing, which has, for its chief rival, Chicago beef, noted for its excellence in the great centers of both continents. Certain cheese and butter products have wide reputation, and deservedly so, because they are prepared from healthy dairies in the pure air of high Alpine fields. The last few years have seen a revolution in the manufacture of butter and cheese from milk brought to a common center from a large surrounding district. The products are so manifestly superior that they bring higher prices in the open markets. These may be called *concentrates* of milk, and, because of their minimizing in bulk and keeping properties, are easily transported long distances to the great centers of consumption. This should pertain equally to the milk-supply, and in the abstract is a problem of comparatively easy solution.

In this paper I purposely avoid even touching upon the important questions of milk composition and the testings of its value, since in a general way, these are not only well understood by the medical profession, but also by the body politic. Sufficient for our present purpose has been the reference already made to the constant contamination to which milk is subject, from the moment of its production until its consumption. It is a well-known scientific fact that aseptically withdrawn from the healthy udder into an aseptic receptacle, and sealed at once without exposure, milk remains indefinitely in a state of preservation. By the present means employed for its abstraction from the animal, protection from contamination is impossible, although to me it seems evidently feasible that machines for milking could be adopted, which, in very large degree at least, would be preventive of this source of infection. Once having occurred, however, some means must be taken for its disinfection. This may be said to be readily done by boiling, but heat thus applied not alone changes the taste of the product, but also its composition, both the fat and casein being affected by it, and rendered far less nutritious and digestible. Heated to a lower temperature, about 170 degrees F—so-called Pasteurization—the cream and caseous products are less changed and the larger portion of the bacteria destroyed. This gives a safer milk and is much more economic in consumption, because it will keep much longer without spoiling.

Milk concentrates, the larger portion of the water having been extracted and condensed by evaporation in vacuo, until a semi-solid is the resultant, have long been familiar to all. They have their advantages and are considered under certain conditions well nigh indispensable articles of food. Their use, however, is comparatively exceptional, because of undesirable changes resulting from the application of heat. By the abstraction of the water from milk, its bulk is les-

sened about 87 per cent. If removed without change of the solids, the addition of this amount of water would again give fresh normal milk. Removal by processes that would destroy deleterious contamination occurring in its production would render the product as permanent as that of butter and cheese, and as easy of transportation. The economic resultant would diminish the cost to the consumer about one-third, and give an article of food of far greater value and safety. How can it be effected?

I am indebted to my friend, William T. Sedgwick, professor of biology in the Institute of Technology, Boston, for much valuable information upon the subject of milk contamination, and the State of Massachusetts may well consider itself fortunate in the services which he has already rendered, in securing a better milk-supply. His publications upon the subject are more or less known to the medical profession. From a large series of bacteriologic investigations the following deductions are drawn:

Normal country milk produced by clean, healthy animals, drawn by hand with great care into sterilized bottles and planted quickly, yielded as an average of several trials 530 bacteria per cubic centimeter—the cubic centimeter roughly estimated as equal to a cube one third of an inch, or to a small thimbleful. When, however, the milkman used the ordinary milk-pail of flaring form, seated himself with more or less disturbance of the bedding, and vigorously shook the udder over the pail during the usual process of milking, we found that the numbers were very much higher, namely, an average of 30,500 per cubic centimeter, at the end of milking. When such milk is found upon the tables of country families a few hours later, it naturally shows still more bacteria, doubtless because those with which it was seeded have had time to multiply. The average of fifteen such samples from the tables of families in Jamaica Plain, Cambridge and Auburndale, was 69,143 per cubic centimeter. In these cases, moreover, the conditions of the cows and of the stables were exceptionally good, while the milkmen were much more than ordinarily clean and careful.

It follows from these results that there are two principal sources of the bacteria in the milk, viz., contamination during the act of milking, and the natural multiplication of the bacteria thus introduced during the interval between milking and the consumption of the milk. The result of these investigations was to show that even under the most favorable conditions cow's milk, as ordinarily drawn becomes, almost necessarily, infected with hosts of putrefactive bacteria at the very outset. Under worse conditions, with unclean stables and dirty milkmen, to say nothing of half-cleaned pails and cans, it is easy to understand why milk swarms with bacteria; and, if we allow time also, the wonder is, not that it contains so many germs, but rather that it is still potable at all.

When we reflect upon the indescribably filthy condition of many cow stables; upon the fact that the cow's udders and flanks are not infrequently covered with flaking excrement; upon the quality of the men employed to do the milking, etc., etc., it becomes a simple matter to understand how this rich animal fluid—sterile at the start, but drawn by unclean hands into half-cleaned pails, and meantime sprinkled from above by the dust of the stable, by hairs, dandruff, dirt, and particles of excrement from the skin and udder of the cow, vigorously shaken by the milker or brushed by his hat—becomes infected with organisms. That these multiply swiftly and enormously in the warm and rich fluid, well aerated by the act of milking, is also a natural consequence of favorable conditions.

Of fifty-seven samples taken directly from the milk wagons and planted at once, the average number of bacteria were 2,355,500 per cubic centimeter. In sixteen samples taken from groceries, usually older milk than that found in the wagons, the average number of bacteria was 4,577,000 per cubic centimeter. Two samples collected from well-to-do families upon the Back Bay showed an average of 1,488,000 per cubic centimeter. Forty-five samples of so-called "railroad" milk, that is produced at a distance from the city and shipped by rail, under favorable conditions even upon its arrival, contained an average of more than 500,000 bacteria per cubic centimeter.

Mr. S. C. Keith, of Boston, a graduate of the institute of technology, who has for two years devoted himself to the special study of milk products and their

contamination, recently gave a most interesting lecture before the Boston Society of Arts upon this subject. He stated that he had made experimental bacteriologic studies during the last summer upon the milk from ninety-seven dairies, examined soon after its arrival in Boston. Twelve per cent. contained less than 100,000 bacteria per cubic centimeter; 51 per cent. from 100,000 to 1,000,000; 25 per cent. from 1,000,000 to 5,000,000; and 12 per cent. over 5,000,000.

Professor Sedgwick quotes the investigations of Professor Renk of Halle, who found that the public milk-supply of that city varied from 6,000,000 to 30,000,000 per cubic centimeter, and he remarks by way of comparison that the sewage of American cities seldom contains, on the average, more than 1,000,000 bacteria per cubic centimeter.

Professor Sedgwick has not been willing to treat the subject from simply the standpoint of abstract science, and at the October quarterly meeting of the Massachusetts Boards of Health in 1897, and published in the JOURNAL, will be found the following rules, suggested by a committee of which Dr. Sedgwick was chairman, for adoption by Boards of Health of the State for the protection of milk supplies from pollution:

ARTICLE I.

SECTION 1. All persons engaged in the production of milk for sale, or in the sale, delivery, or distribution of milk in the city or town of . . . shall annually, on or before May 1, make written application, on forms prescribed by the Board, for a permit or license.

SEC. 2. No person shall engage in the business of producing milk for sale, or in the sale and distribution of milk, in the city or town of . . . after April 30, 189-, without a permit or license to do so signed by said Board of Health, and under such conditions as said Board of Health may impose, revocable at the pleasure of said Board.

SEC. 3. The conditions under which every cow is kept, whose milk is brought into any city or town, or kept, delivered, distributed, sold, or offered for sale, in such city or town, shall be made known to the local Board of Health in such detail as the Board may require, and shall be approved thereby; and no milk except that delivered from such cows shall be brought, kept, delivered, distributed, sold, or offered for sale.

SEC. 4. No milk shall be sold, offered for sale, or distributed in any city or town, unless the cows from which it is delivered have within one year been examined by a competent authority, and shown to the satisfaction of the local board of health to be free from disease.

SEC. 5. All persons having a permit or license to sell, deliver, or distribute milk in any city or town, shall keep a copy of the same constantly posted in a conspicuous place on premises and vehicles from which milk is sold or distributed or in which milk is kept or delivered.

ARTICLE II.

SECTION 1. No milk shall be kept for sale or distribution, or handled, transferred from can, or stored in any stable or similar place, or any room used in whole or part for domestic or sleeping purposes.

SEC. 2. Milk shall be stored or regularly mixed, cooled, or poured from can to can only in a room not directly connected with a stable or stables, provided with a tight floor and kept constantly neat and clean, the walls of the room being of such a nature as to allow easy and thorough cleaning. The room aforesaid shall contain proper appliances for washing and sterilizing all utensils actually employed in the storage, sale, and distribution of milk in said building, and all such apparatus and utensils shall be washed with boiling water or sterilized by steam regularly after being used.

SEC. 3. No animal, water-closet, or privy shall be in the aforesaid room or any room directly connected therewith.

SEC. 4. All milk directly after it is drawn from the cow shall be at once taken to, and be at once filtered, cooled, and stored in a room such as is described in Article II, Sections 1 and 2.

ARTICLE III.

SECTION 1. Milk kept for sale in any store, shop, market, bakery, or other establishment, shall be always kept in a covered cooler, box, or refrigerator, properly drained and

cared for; and while therein shall be tightly corked or closed, and only in such location and under such conditions as shall be approved by the local board of health.

ARTICLE IV.

SECTION 1. All cans, bottles, or vessels of any sort used in the sale, delivery or distribution of milk to the consumer must be cleaned and sterilized by the milk dealer before they are again used for the same purpose.

ARTICLE V.

SECTION 1. Every person engaged in the production, storage, transportation, sale, delivery, or distribution of milk, shall immediately on the occurrence of any case or cases of infectious disease, such as typhoid, scarlet fever, or diphtheria, either in himself or in his family, or among his employees or within the building or premises where milk is stored, produced, sold, or distributed, take care that the local board of health is notified of such case or cases, and at the same time suspend the sale or distribution of milk until authorized to resume the same by the local board of health.

SEC. 2. It shall be unlawful for any person suffering from a contagious or infectious disease, such as typhoid, scarlet fever, or diphtheria, to handle, transport, deliver, mix, taste, work over, or distribute milk, or in and about places where milk is stored, sold, or distributed, or to serve as a milker or milkman. No vessels which have been handled by persons suffering from such diseases shall be used to hold or convey milk.

A long discussion of these rules was entered into by the members of the Massachusetts Boards of Health, which resulted in their adoption, and as a fruitage thereof, I subjoin the following order issued by the Board of Health of the town of Montclair:

BOARD OF HEALTH.

AN ORDINANCE CONCERNING THE PRODUCTION OF MILK AND REGULATING ITS SALE AND EXPOSURE FOR SALE IN THE TOWN OF MONTCLAIR.

Be it ordained by the Board of Health of the Town of Montclair, in the County of Essex, as follows:

SECTION 1. Every person, corporation or association of persons who now is or who hereafter shall be engaged in the sale, or exposure for sale of milk within the Town of Montclair, before selling or exposing the same for sale, shall furnish the Board of Health of the Town of Montclair a true and complete statement as to the locality from which the milk so sold or exposed for sale is produced; also a full and complete list of the names and addresses of persons from whom the said milk was purchased, and the names and addresses of all persons to whom they are regularly selling or delivering milk within said town; said lists shall be furnished to the said Board on the first days of January, April, July and October of each calendar year, and at all other times when requested by the said Board.

SEC. 2. No milk shall be sold or exposed for sale in the Town of Montclair except milk from cows stabled under light, dry and well ventilated conditions, and in all other respects conforming to the requirements hereinafter set forth, viz:

a. Each cow shall have at least three feet in width of floor space when fastened in stanchions, and in all cases where no adequate artificial means for ventilation are provided, each animal shall have an air space of at least five hundred (500) cubic feet.

b. All stables for shelter of said cattle shall be provided with a tight, dry floor. The manure drop shall be water-tight, and if constructed of wood shall be asphalted, tarred or otherwise made non-absorbent.

c. The walls and ceilings of said stables shall be whitewashed whenever it may be deemed necessary by this Board of Health.

d. Manure shall not be allowed to accumulate in large quantities in stable yards, nor near the buildings where the cattle are kept, and when stored temporarily in such places it shall be removed at least once per month. The said stable yards shall be drained and kept in a clean, dry condition, and no accumulation of household garbage, vegetables or other putrescible matter shall be allowed to remain or decay in said stable yards.

e. Cattle shall at all times be kept in a clean condition, and udders shall be washed, hand rubbed or wiped with a clean, damp cloth before each milking.

f. No milk shall be sold or offered for sale or distributed in the Town of Montclair, unless the cows from which it is obtained have, within one year been examined by a competent veterinarian, and are free from diseases dangerous to the pub-

lic health. But this shall not be construed as forbidding the sale or use of milk from cows not tested with tuberculin.

g. No milk shall be sold or offered for sale or distributed in the Town of Montclair, obtained from any cow that has calved within ten days, or from a cow which will come in or calve within sixty days.

SEC. 3. No milk shall be sold or exposed for sale in the Town of Montclair, except milk produced from cattle fed and watered under the following conditions: All food given to such cattle shall be fresh, sweet and wholesome. The use of either distillery slops or fermented brewer's grains is prohibited, and their presence on any dairy premises will be considered sufficient cause for the exclusion of the milk from such dairy from sale or delivery in said town. Water supplied to cattle shall be pure and free from all contamination by stable or household drainage, and no well or spring in or adjoining any stable yard shall be used for watering said cattle.

SEC. 4. All milkers and other attendants employed in any dairy, the milk from which is to be sold or offered for sale or delivered in said town, shall be personally clean. Before entering upon their duties connected with the dairy, hands shall be washed, and clothes changed or brushed, and no milk shall be delivered or sold or exposed for sale in said town, produced from dairies wherein the foregoing regulations are not enforced.

SEC. 5. Utensils used for the collection and transportation of milk shall, before being used, be thoroughly washed with pure water and soda or soap, and then sterilized by boiling or steaming.

SEC. 6. Milk which is to be delivered or sold or offered for sale in said town shall, immediately upon being drawn from the cow be removed from the stable to a room separate and apart from the said stable, and immediately cooled by submerging the vessel in which the milk is contained in cool water to a depth equal to that of the said milk in the vessel. The above mentioned room shall be properly ventilated and lighted and shall be used for no other purpose than that indicated above, and shall at all times be kept in a clean condition.

SEC. 7. The said milk shall be delivered in bottles unless permission for delivery in another manner shall be granted by said Board. No tickets shall be used in connection with delivery of milk.

SEC. 8. If at any time any person or persons having any connection with a dairy from which milk is delivered or sold or offered for sale in the Town of Montclair, or any resident member of the family of any person so situated, shall be stricken with cholera, smallpox, (including varioloid), diphtheria, membranous croup, yellow, typhus, typhoid or scarlet fever, measles or any other communicable disease that may hereafter be declared by this Board to be dangerous to the public health, notice shall be given to said Board immediately, by the owner or owners of such dairy, and no milk produced from the dairy of any corporation, person or association of persons failing to give the notice herein required, shall hereafter be sold or exposed for sale or delivered in the Town of Montclair, until special permission therefor has been granted by said Board.

SEC. 9. Any person, corporation, or association of persons, violating any of the provisions of this ordinance, shall, on conviction thereof, be liable to a penalty of not less than ten nor more than one hundred dollars.

SEC. 10. All ordinances or parts of ordinances inconsistent with the provisions of this ordinance are hereby repealed.

Passed March 25, 1898.

Attest:

R. P. FRANCIS, Secretary.

D. D. DUNCAN,
President.

My friend, Dr. J. Cheston Morris of Philadelphia, one of the best known authorities upon the subject of milk-supply and distribution, writes me under recent date and in reply to the question, Where can milk be most satisfactorily produced? "On a farm where the animals can browse contentedly on green grass, near running waters, and can find good shelter, plenty of hay, corn fodder, corn and cob meal in winter, warm, well-lighted and aired stables. Keep animals clean, dry, well-fed and freely exercised. Stimulate them unnaturally and disease may follow. Breed only from healthy animals and avoid unhealthy care-takers. My Devon cows are giving me about five and a half times their weight in milk per annum, which furnishes four quarts of cream or four pounds of butter from twenty-eight quarts of milk. I think a machine that keeps itself in order and produces a new machine

annually, beside five and half times its own weight, without undue urging, a pretty good machine, and I am satisfied. I do not believe we can preserve milk as it comes from the cow and with digestibility undiminished for more than thirty-six to forty-eight hours."

Dr. Morris refers to a very recent discussion having taken place in Philadelphia over the best methods of handling and distributing milk, resulting in the approval by the Board of Health of the glass jar distribution, well known to have been originally introduced by Dr. Morris. The advocates of the large-can process of distribution objected to the glass-can system on the ground that contagious disease might be carried from house to house by imperfectly disinfected jars, but Dr. Morris states, "I showed that I had carried on this method of distribution for more than twenty years without a single case of such carriage, either among customers or at the farm; that for the farmer's own protection, as well as for his profit, absolute practical disinfection for each jar is indispensable."

It is apparent that a rigid supervision under State authority would do much toward the protection of the public, by furnishing milk produced by healthy cattle, kept reasonably clean, sent to market much cleaner and better preserved; in a word, safer for public consumption.

As shown by Professor Sedgwick, to a degree at least, it is necessarily an infected article and consequently must undergo decomposition within a limited period, that placed by such a distinguished authority as Dr. Morris not exceeding forty-eight hours.

Dr. Morris' method of requiring each producer to put up his milk in pints and quarts in glass jars, with the name of the dairy and the date of milking has manifest advantages. Any defect in the supply or cause of disease, as, in illustration, the repeated occurrence of typhoid fever (epidemics disseminated by the milk-supply) can be easily traced. It also stimulates rivalry and fosters a local pride among the farmers. It is noteworthy to observe the much better keeping quality of milk thus prepared for the market.

Illustrative specimens were shown by Dr. Morris, when lecturing upon the subject some time ago in Boston, that were perfectly fresh and sweet when the jars were opened four days after the milking, although subjected to the long journey from Philadelphia.

On a model farm near Boston the process of milk preservation is carried on in the following simple and effective manner: Having been milked as cleanly as possible, the milk is poured into a receptacle and by gravity finds its way through a series of strainers into an adjoining apartment having no other connection with the stable. Here it is quickly refrigerated and put up for market.

To aid in a cleaner process of milking, a pail has been devised called the "climax milkpail." It consists of an ordinary pail with a tightly fitting cover with two openings from which funnels project considerably above the surface of the cover. The bottom of these funnels is covered with close-meshed wire strainers. By its use much of the dirt which ordinarily falls into the pail from the udder is avoided. Pure rubber covers of a size to enclose the entire teat ending in a rubber tube, to conduct the milk into a closely covered pail could be used without much difficulty after a little practice with them on the part of the milker. They would be of the highest service,

cheap, easily cleaned, and with reasonable care, furnish an almost absolutely sterile milk.

Mr. Horlick of Racine, Wis., quite recently described to me a most ingenious device for milking cows by a machine, the power of which is furnished by an electric motor. It is said in many ways to work satisfactorily, and by an ingenious combination may be applied to the milking of even fifty cows at the same time. All these methods are advancements in the right direction, to which may be added what, in a limited degree, has already been carried into effect—the process of sterilization by the application of a low grade of heat, Pasteurization, that is, maintaining the milk for a considerable period at a temperature of about 170 degrees F., not high enough to be detrimental to the albuminoids. Even if sterilization by this method is effected, contamination is sure to follow upon subsequent exposure to bacterial infection.

The secretion of the mammary gland is the product of certain epithelial cells. By their transforming power they manufacture from the blood a mixture of fat, sugar, and salts in a watery solution which we call milk. It is in fact strictly an animal food of unstable composition and is easily decomposed under the action of bacterial development. A pound of very lean beef and a quart of milk each contain about the same quantity of actual nutritious material. The taste which is objectionable in sterilized milk may be modified by pouring the milk from one receptacle to another, thus aerating it. In certain parts of the country Pasteurized cream has become popular. It is more conveniently handled and, freed in large measure from bacteria by the process, will keep for days without souring. It is objected to because of its lack of consistency, being thinner and less viscous. The Wisconsin Agricultural Experiment Station, after a careful study of the subject, recommends the use of lime dissolved in a solution of granulated sugar. This is called "viscogen," on account of its viscous producing properties, and the treated products are called visco-cream, visco-milk, etc. Only one part of viscogen to one hundred and fifty parts of cream is required, and the small quantity of lime added according to this rule only amounts to about four parts in 10,000, which, instead of being detrimental to the health, is rather beneficial.

In several European cities sand filtration of milk is employed at a central depot after its arrival from the country. The filters consist of large cylindrical vessels, divided by horizontal, superposed compartments, of which the middle three are filled with fine, clean sand, sifted into three sizes, the coarsest being placed in the lowest and the finest in the topmost of the three compartments. The milk enters the lowest compartment through a pipe under gravitation pressure and, after having traversed the layers of sand from below upward, is carried by an overflow to a cooler fed with ice water, whence it passes into a cistern, from which it is directly drawn into locked cans for distribution. Milk thus treated is not only free from dirt, but the number of bacteria is reduced to about one-third. In new milk the loss of fat is said to be very slight, but the quantity of mucus and slimy matter retained in the sand is surprising. The sand is renewed each time the filter is used.

The live stock interests of our country are so enormous that it is difficult to form a just appreciation of their value. According to the census of 1890, there were that year in the United States between fifty-one

and fifty-two millions of cattle, calves born over sixteen and one-half millions, and the total number of milch cows were 16,511,950, of an estimated value of over \$4,000,000,000. The milk-supply for 1889 reached the enormous aggregate of 45,210,125,567 gallons, worth on the farm over \$651,000,000.

The census of 1890 gives us the latest reliable data, but there has been a material increase in the value of the milk-supply in excess of the ratio of the increase of population. It is only by comparison that such enormous amounts can be appreciated. The total value of all the mineral and metal products, including coal, of 1896 are given as follows:

Belgium	\$100,000,000
France.	110,000,000
Germany.	300,000,000
United Kingdom	340,000,000
United States.	737,958,761

Some years since Mr. Edward Atkinson of Boston showed that the *hen* was a greater producer of material wealth than the gold mines of the country. From the above figures we note that the *cow*, by her milk product alone, is a source of wealth not far below that of all the mineral products of the United States.

The butter product for 1889 was 1,024,223,468 pounds and the cheese product for the same year was 18,726,818 pounds. The average quantity of milk produced for milch cows during the year 1889 was $315\frac{5}{10}$ gallons, and to each individual in the United States for the year was $83\frac{1}{2}$ gallons, or nearly one quart per day for every man, woman and child in the entire country. Estimating that six-tenths of the product was canned and shipped for distribution, the amount thus disposed of was 25,008,602,718; analytically 87 per cent. is water, and at least 75 per cent. of the water should be removed before shipment. The amount of *water* thus expensively distributed with only attendant loss, is so enormous that it can be appreciated only by means of comparison—18,756,452,037 pounds equal 9,378,226 tons = 468,911 car loads each of 20 tons = 11,725 train loads, each of forty cars = 2931 miles of continuous trains, reaching nearly from the Atlantic to the Pacific Oceans if thus placed to span the continent!

Were it possible to eliminate this enormous percentage of waste without damage to the resultant product, the gain would be almost beyond comprehension.

G. W. Goddard of Cambridge gives the following figures from New York City Board of Health Report: 1896, pp. 90, 91. Daily average of cows' milk and condensed milk shipped to New York City: Milk 828,612 quarts, cream 16,000 quarts, condensed milk 8600, a total of 853,212 quarts. To give milk equivalent to the cream add 64,000 quarts. To give milk equivalent to the condensed, add 19,800 quarts, making a total of milk-supply 937,212 quarts, condensed 75 per cent. of the whole; 87.7 per cent. of above is produced in New York State; in New York City 2200, in State 1,112,370, in all 1,114,570 cows. Total cost at five cents per quart, over \$60,000,000 per year.

The Agricultural Department at Washington has just issued one of its bulletins, treating of the milk-supply of Boston and other New England cities, and prepared by Mr. George M. Whitaker, executive officer of the Massachusetts State Dairy Bureau. The Greater Boston, namely, within a radius of ten miles from the State house, contains a population of one million, or eighteen per cent. of the population of New England.

About three-fourths of the supply of milk for this section is sent by railroads, the greatest distance for direct shipment is 140 miles. For the most part the milk is conveyed in cans especially constructed for this purpose with refrigerator closets, etc. The milk thus supplied is from eighteen to thirty hours old before it reaches the consumer. Boston was the pioneer city in this country in the transportation of milk by railroad. The first man to engage in this business was Jason Chamberlain, who began operations sixty years ago upon the Boston & Worcester railroad. He sold milk at twenty-five cents per can of nine and a half quarts. In 1843 there was printed in the *New England Farmer* an article upon the subject. It states, "We have learned that one man brings in upon the Worcester railroad 200,000 gallons annually. This is supposed to be one-tenth of all that is sold in the city. This at twenty cents a gallon costs the citizens \$400,000 per year." Today fully three-quarters of the milk supplied to Greater Boston passes through the hands of large wholesalers, locally known as contractors. There is a considerable increase in the consumption of milk in Boston each year. The total for 1895 was about 18,000,000 gallons—in 1897 the supply had increased nearly 700,000 gallons. Within the ten-mile radius there are over 7000 cows.

Mr. B. F. McIntyre, of McKesson & Robbins, New York, has recently published some interesting articles upon the condensing of milk by a process of refrigeration when the milk is in agitation. His more recent publication is found in the *Milk Reporter*, January, 1897. His experimental studies were carried on at Cattaraugus, N. Y., under favorable refrigerating conditions. The product met the approval of dealers from both the commercial and economic standpoint. His process is briefly summarized as follows:

1. Reducing the bulk of the milk by conversions of the water of the milk into ice, instead of vapor or steam.

2. The making of the ice on the surface only of the milk, by elevation of the freezing pans in an atmosphere of zero temperature or thereabouts.

3. Frequent breaking of the surface ice so that fresh liquid is presented to a freezing effect, with gradual submersion of the broken ice as the bulk of ice increases.

4. Standardization of the product.

Considerable difficulty was experienced in the selection of milk free from "cow-odor." Milk with a perceptible taint of animal odor is unfit for condensation by cold processes as thereby these odors are intensified. The fats are removed by a cream separator which should be set to run heavy cream and which should assay not less than fifty per cent. milk fat. Running into the separator is of much value in freeing the milk from dirt and foreign animal products. From the separator the fat-free milk was run over a bank of horizontal copper pipes through which ice water was circulated reducing the temperature of the milk from 80 to 35 per cent. F. By this process of condensing there is no thickening of or chemic change in the albuminoids, such as takes place when the milk is reduced by heat in vacuo. A condensation of five and one-half gallons to one gallon is required to produce a product with the desired consistency. By this freezing process one hundred gallons of skim-milk are reduced to thirteen gallons of very thick milk which represent in milk, sugar, caseine and inorganic salts fully nine gallons of solids.

Eighty-seven gallons of water in the milk are formed into ice. An average sample of the snow-like ice, when melted and evaporated to dryness contained .2 per cent. of residue. A final step in the process was the admixture of the heavy cream in proper proportions with the concentrated fat-free milk. In keeping properties the new form of condensed milk is superior to whole milk, as the freezing temperature at which the milk is held is destructive of some forms of germ life common to milk, and the natural life of the preparation is prolonged by this partial sterilization."

I am in receipt of letters from Mr. McIntyre, of recent date, in which he states, that "unfortunately the plant at Cattaraugus has recently been burned," and in reply to my inquiry as to the expense attendant upon this process of condensation, he states: "The cost of the manufacture of ice *per se* from milk is not so very much greater than making it from water. My process could be designated as a method to produce ice in crystal form, instead of in solid or cake form, and the solids of the milk might be considered as a foreign admixture to the water being subjected to the freezing effect. I claim, and have the judgment of experts, that my process will produce as much ice daily from a given weight of coal, as will be produced in the ordinary ice-making process. Ice made from distilled water is sold in New York in midsummer at \$2.00 per ton."

If the condensation can be carried on by a process by which the water of the milk can be extracted at any such cost as above estimated, it will at once be accepted as of the largest value. It seems feasible and merits a careful consideration, as introducing a possible new factor of the greatest value in furnishing economically a daily product of such an indispensable character as milk.

The condensation of fluids in vacuo has been economically conducted, at a very recent period, at a much lower rate of temperature than was formerly deemed possible. I am advised by two New York chemists that one of our large manufacturers of malt products is successfully carrying out a process with the temperature as low as 110 degrees F., in vacuo and it is believed not improbable that milk can be evaporated to dryness at a temperature of 100 degrees F. This temperature would scarcely affect in any way the albuminoids and would leave a product unchanged except for the abstraction of the water.

It seems thoroughly feasible to treat milk in large quantities by abstracting the great bulk of the water through refrigeration, thus practically sterilizing the resultant product. This product, treated by evaporation, either in vacuo at a low temperature or by a warm air blast, the heat-point of which is regulated so that the resultant product may be in the form of granules, cakes, or of a consistency not unlike that of butter or cheese, all possessing good keeping quality, would, upon the addition to it of the proper percentage of water, furnish fresh milk at will.

In these days of rapid progress the public is accustomed to accept radical changes, when demonstrated for the better, with very little of comment. The immense problem which I have thus all too briefly outlined, viz., furnishing vastly more economically a safe and satisfactory milk-supply is worthy the attention of all sanitary scientists. Clearly formulate the *want* and show the manifold advantages resulting from *better methods*, and science at once steps in

and demonstrates the *way* for their attainment. This, I believe, will early be accomplished. The milk-supply of the world will be economically revolutionized, to the manifest advantage of every individual.

A further study of Mr. McIntire's processes increased my interest in the subject until, after a correspondence of some length, I induced my friend, Mr. George M. Goddard of Cambridge, a well-known expert in the processes of refrigeration, to visit New York and carefully examine the method advocated by Mr. McIntire. The outcome of this, through Professor Sedgwick, has been to secure the active co-operation of Mr. Edward Burnett, who has devoted a large share of his life to the scientific studies relating to agriculture, and especially the better methods of milk production and distribution. Mr. Burnett's large milk-plant at Southboro was placed at Mr. Goddard's disposal and the summer occupied in a careful practical study of the processes. Samples of the concentrate were distributed for experimental use. Those which came under my observation proved in every way satisfactory. The oldest specimen examined, having been kept thirteen days, was perfectly sweet when opened. A careful series of bacteriologic tests, by the request of Professor Sedgwick, were undertaken by Prof. G. M. Holman, of which the following tables furnish brief samples:

TABLE I.—First Series (Aug. 1, 1896.)

Sample.	Bacteria per c.c.	
1 Whole milk	267,400	Numerous liquefiers.
2 Skim milk (pan)	432,600	
3 First condensation	394,200	Odorless plate.
4 Second condensation	175,000	Mouldy cheese odor.
5 Third condensation	24,000	Sweet butter odor; 1100 liquefiers.
6 Fourth condensation	19,400	Sour milk odor; few liquefiers.
7 Pasturized cream product	175,000	Mouldy odor.
8 Raw cream product	2,616,100	Many moulds.
9 Raw cream product	2,759,400	
10 Pasteurized cream	0	Plate covered with moulds (mucus).
11 First ice	6,370	Some moulds.
12 Second ice	3,444	Some moulds; badly liquefied.
13 Third ice	1,470	Many moulds; badly liquefied.
14 Fourth ice	17,000

Reduction of bacteria from the whole milk to the finished (Pasteurized cream) product, 94.2 per cent.

It will be noted that the bacteria are very greatly diminished by the refrigerating process, although the product is not absolutely sterile. A special plant is now being established, where it is believed that much better work may be accomplished with a great reduction of cost. The daily output will be at the beginning 600 gallons reduced to 100 gallons, the product having already been disposed of. It is confidently believed that the result will assure an abundant reason why the milk distribution may be greatly improved, giving a far more reliable product, of good keeping quality, at a much less cost to the consumer. If, for commercial reasons, it does not prove profitable to carry the process of concentration above the result outlined, the ordinary family supply of milk may be furnished weekly instead of daily and a far better product obtained than that of the present.

I have in my possession a specimen of powdered milk made by Mr. McIntire nearly two years ago, in a state of good preservation; thus demonstrating that the so-called butter fat of milk can be preserved in mixture. Mr. McIntire is of the opinion that it is easy to concentrate the solids of milk to a consistency not unlike butter or soft cheese, which will require only the addition of a proper amount of water to restore it to a sweet, wholesome, fresh milk, containing its proper quantity of normal cream. The keeping quality of this product will be such that it will come into world-wide distribution.

IMPORTANCE OF REGULATING DIETETICS

IN HARMONY WITH THE PHYSIOLOGIC LAWS CONTROLLING DIGESTION, NUTRITION AND WASTE, AND SOME OF THE INCONSISTENCIES IN PREVALENT DIETETIC PRACTICES.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY N. S. DAVIS, M.D.
CHICAGO, ILL.

That the quantity and quality of food for man, and the times for taking it, should be regulated in harmony with the physiologic laws governing the processes of digestion, assimilation, nutrition, disintegration and excretion, is too obvious to the intelligent physician to require argument or illustration.

The fact that all living animal structures are constantly undergoing disintegration atom by atom or cell by cell, renders it necessary that there should be constantly present in the fluids permeating the structures, new atoms or cells or vitalized materials, ready to take the place of materials lost, and thereby maintain the integrity of the tissues.

During childhood or youth, or period of growth, the amount of food assimilated must exceed the amount lost by disintegration or there would be no

progressive development of the various parts of the body. But in adult life the amount of true food or ingests each day should equal as near as possible the amount of loss by the processes of waste. It is not practicable, however, to establish the actual amount of food required daily by any individual in health, by simply determining the average amount of waste he suffers, unless such determinations include the variations produced by different degrees of physical exercise and mental activity. For it is well known that the activity of both nutrition and waste are much influenced by the amount of physical exercise accomplished in a given time, while it is equally true that mental cheerfulness, confidence and activity increase all the physical functions, and that grief, despondency and fear diminish the same. Another factor of great importance, though often omitted when considering the subject of dietetics, is the quantity of oxygen received through the lungs into the blood in a given time, and the conditions of the atmosphere from which it is derived. In the popular mind, diet or food is considered only in reference to the materials received into the stomach in a solid or liquid state, while no thought is given to the quantity or quality of the atmospheric air supplied to the air-cells of the lungs, from which oxygen is being constantly taken up by the blood-currents and distributed to every living structure in the body. When we consider, however, that the oxygen thus derived is nature's excitator of all nerve sensibility and muscular contraction, as well as the active oxidizer of all waste products, we are compelled to recognize it as an essential factor in all the processes of assimilation, tissue metabolism, and excretion. And it becomes as necessary for each individual to secure a sufficient amount of pure air for the lungs, as it is an adequate supply of pure food for the stomach, for universal experience has shown that without a constant supply of the former, the digestive and assimilative organs soon cease to make a healthy and efficient use of the latter. But as nature supplies the air in unlimited quantity at all times without man's labor, his chief ingenuity has been exercised in devising ways and means for either impairing its quality or limiting the quantity to be inhaled, thereby limiting the quantity of its oxygen supplied to the blood. This is seen, not only in the serious interferences with respiratory movements by erroneous habits of dress for the day and the occupancy of small or ill-ventilated rooms for the night, but also in the construction of over-crowded, ill-ventilated and uncleanly houses and workshops, of every kind, for working men and women, by which they are compelled to use both an impure and an inadequate supply of air alike in the shops and the homes.

Nor is this all, for one of the most injurious effects of the enormous quantity of alcoholic drinks and tobacco used in this and other countries, is their influence in lessening the efficiency of respiratory movements and the capacity of the blood to receive and distribute oxygen to the tissues of the body. Experimental therapeutists have fully established the fact that alcohol, by its anesthetic or paralyzing influence on the respiratory nerve center, diminishes the depth of the respiratory movements, thereby lessening the amount of air used, in direct proportion to the quantity taken, and at the same time by its action on the hemoglobin and corpuscular elements of the blood, it lessens the capacity of that fluid to receive oxygen

from the pulmonary air-cells and to carry it to the various tissues of the body. It is by this duplicate interference with the reception and internal distribution of oxygen, that alcohol retards tissue metabolism, encourages the retention of effete products, and lessens the vital resistance to all toxic agents, including pathogenic bacteria, as was so strikingly demonstrated by the recent experiments of Professor A. C. Abbott.

The effects of the use of tobacco on the important functions of the human body have not been demonstrated by as much scientific investigation as those of alcohol, but enough has been done to prove that enough of the active constituent called *nicotine* is imbibed either by smoking, chewing or snuffing to lessen the sensibility of the nervous and muscular structures and to impair the steadiness and efficiency of both the cardiac and respiratory functions. In doing this it necessarily lessens the oxygenation and decarbonization of the blood, and thereby impairs all vital processes in proportion to the quantity used. This has been shown most strikingly by comparing the progress, both physical and mental, of student smokers, in the same classes and subject to the same regulations in other respects, in the schools of France and in some of the colleges in the New England States. These comparisons have uniformly shown that the students who use tobacco, chiefly by smoking, averaged less physical growth and less progress in mental attainments than those who did not use it—the records extending through school periods of three and six years.¹ This effect of tobacco in retarding the physical development and mental progress during childhood and youth has been so fully demonstrated that all investigators agree that its use should be wholly avoided until the commencement of adult age. But if its narcotizing effects upon the cerebrospinal nerve structures and the organized elements of the blood are sufficient to retard both mental and physical growth and activity before the age of twenty years, will not the same narcotizing influence just as certainly lessen the activity of the same structures at any time after the age of twenty years, and thereby lessen the vital resistance to morbid agencies and shorten life?

The use of tobacco not only lessens the efficiency of respiratory movements and the internal distribution of oxygen, but it exerts a special deleterious influence on the heart, often disturbing the uniformity of its rhythm and impairing its force, and not unfrequently causing sudden death by cardiac paralysis.² From the foregoing statements it is evident that a just consideration of dietetics must include all ingesta habitually used, whether solid, liquid or gaseous; through the respiratory as well as through the digestive organs. And such ingesta must not only contain a sufficient quantity and variety of materials to equal the amount of waste from day to day, but they must also be free from such elements as are capable of impairing one or more of the important processes concerned in assimilation, nutrition and secretion.

The ingestion of oxygen and the elimination of carbon dioxid through the lungs is a continuous process, though varying in rapidity during different parts of the day in harmony with the greater or less activity of other functions. Thus oxygen is received and car-

bon dioxid eliminated more rapidly during active muscular exercise than during repose. The same increase takes place during the first two hours after the ingestion of ordinary food into a healthy stomach, and becomes the slowest in the early morning when the stomach and duodenum are most free from food. These variations are accompanied by corresponding changes in the temperature of the body and in tissue metabolism, and being strictly physiologic, they have an important bearing on the proper regulation of diet for the stomach. In all the higher orders of animals the digestive organs and the mental part of the brain are designed for regular diurnal periods of activity and rest. And it is still more true in regard to these organs in men, whose greater mental development and more varied occupations render continuous feeding impracticable. If the stomach, in its capacity and the laws governing its action, render it necessary to take food at stated intervals, it is evident that such intervals should be sufficient to complete the digestion and leave a period of gastric repose before the next meal. As a judicious meal of wholesome foods requires for its complete digestion from three to four hours, and if we add from two to three hours for gastric repose, it would indicate the desirability of not eating in health more frequently than once in six hours during the day, and double that time for the night, when the mind is supposed to rest in sleep. The very general custom of taking three meals per day is, therefore, in harmony with the physiologic laws governing the functions of the body. The amount and variety taken at each meal should be sufficient to supply all the elements necessary for growth and repair, and in such form as to be readily acted upon by the salivary, gastric and pancreatic secretions, and assimilated or vitalized by contact with the oxygen and corpuscular elements of the blood, and thereby fitted to become a part of living organized structures. The rapid progress of organic chemistry during the middle part of the present century, by which both the ultimate and proximate elements entering into the composition of the various structures, organs and secretions of the human body were made known, as well as the composition of all important food products, led physiologists to adopt an almost exclusive chemico theory of digestion, assimilation and nutrition. Finding the salivary, gastric, pancreatic and hepatic secretions each containing active constituents capable of combining with, or modifying some of the proximate elements of the food taken, the chemico-physiologists soon began to manufacture in their laboratories substitutes for, or aids to, the natural secretions, and have continued until the drugstores are filled with an almost endless variety of pepsines, peptones, enzymes, etc., each one of which is guaranteed to digest, or more properly dissolve, a given quantity of fibrin, albumin or protein in a test-tube kept at a proper temperature. Not satisfied with thus furnishing us with artificial aids to our natural digestive fluids, they have undertaken to condense, modify or pre-digest our food products before we eat them, to such an extent that we are at every turn urged to go for food to the apothecary shop, laboratory or the "liquid beef" manufactory, instead of the grocery, the meat-market and the farm. And yet it is probable that disorders of digestion and assimilation were never more prevalent than at the present time, when every such disorder is sought to be corrected by some new food preparation or artifi-

¹ Effects of Nicotine, by J. W. Seaver, A.M., M.D., Quarterly Journal Inebriety, April, 1897, p. 132.

² Lectures on the Action of Medicines, Lauder Brunton. Pp. 321-323, 1897.

cial food digester, instead of seeking out the causes of the disorder and endeavoring to remove the same. The natural digestive fluids are the products of vital activity in living structures. The salivary glands, the gastric tubules, the pancreatic and hepatic cells and the structures in which they are imbedded, are all endowed with vital properties, and the digestive and assimilative processes are *vitalizing* and not merely chemic changes. The chemist may mix any one or all the elements of food with either artificial or natural digestive fluids in glass tubes or earthen vessels and he may effect their solution, but he would never produce either true chyle, lymph or blood, much less an organized structure. As well might he put an unimpregnated ovum into his incubator, and expect in due time to have a live chicken instead of a decayed and odorous mass within the shell. While it is important that the quantity and quality of our food, and the times for taking it, should be duly proportioned to the amount and kind of retrograde metabolism or loss, it is equally important that we avoid those influences that habitually interfere with the due oxygenation and decarbonization of the blood or depress the functions of the pneumogastric and vasomotor nerves.

The occupancy of overcrowded or ill-ventilated rooms either for sleep or work; the neglect of sufficient open-air exercise during some part of the day; the eating in haste and the indulgence in intense mental activity, anxiety or violent emotions directly after meals or until late hours of the night; and the ordinary use of alcohol and tobacco, are the chief causes of those digestive disorders that have given us the credit of being a nation of "dyspeptics." And an analysis of their mode of action will show that all of them, either directly or indirectly, lessen the efficiency of the respiratory function and the internal distribution of oxygen. That close and persistent mental application in-doors lessens the depth of the respiratory act and consequently lessens the quantity of air used in the lungs and of oxygen imparted to the blood, has long been known.

And mental anxiety and depressing emotions much increase this effect, and sometimes suspend the secretion of gastric juice entirely while the stomach is full of food, while the effect of both alcohol and tobacco have been explained already. If it is an established fact, as previously stated, that oxygen is taken up from the air-cells by the blood-currents much more rapidly during active digestion of food, then certainly all the causes enumerated above should be avoided to the greatest possible extent during the taking of food and for one or two hours thereafter.

Our food should be taken with mental cheerfulness, without haste, and in an atmosphere of fresh, pure air; and for the next hour, at least, only moderate mental or physical labor should be engaged in and all obstructions to full respiratory movements avoided. The general observance of this simple dietetic rule would add immensely to the sum of human happiness, and materially prolong the average duration of human life.

A Valued Friend.—She: Dr. Reaper tells me that he is not only your family physician, but a warm friend of yours. He: Oh, yes indeed, and I can recommend him very highly. She: Has he ever treated you? He: No, not personally. But he was very successful with a wealthy aunt of mine.—*Harts-horn's Roller.*

FUNCTIONAL NERVOUS DISTURBANCES IN PULMONARY INVALIDS.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY S. G. BONNEY, A.M., M.D.

Professor of Medicine in the University of Denver; Visiting Physician, St. Luke's Hospital.
DENVER, COLO.

During a six years' experience with pulmonary tuberculosis in Colorado, with opportunities for continued observation of cases, I have been enabled to note the very frequent association with this disease of the various forms of functional nervous disturbance. The conviction has arisen that there exists a relation more intimate than is perhaps generally recognized between these conditions, which may be justly considered the two most prevalent of American disorders.

A brief review of my clinical observations suggests itself as a means of directing more attention to this relationship, in the hope that ultimately further researches may afford a clearer conception of the subject. Without attempting to introduce any physiologic considerations, I will simply present the result of my own experience with reference to etiologic relations, prognosis, climatic influences and management. It is with much hesitation that I submit this report, realizing only too well the opportunities for error in the compilation of statistical records and the frequently resulting fallacies as to conclusions. I may state that while rather definite impressions as to certain phases of the subject have necessarily been received from daily general experience prior to the present inquiry, the study is here pursued without reference to any preconceived conclusions, with a view to securing more accurate information upon which to base opinions until then held in reserve. I am appreciative of the fact that the value of work of this nature depends entirely upon the authenticity of the records, the degree of intelligent discrimination possessed by the observer, and the most rigid and conscientious attention to detail.

Unfortunately, in a considerable number of the cases my records are incomplete from the standpoint of the neurologist. Some of the histories were imperfectly taken in this respect, and I am unable, therefore, to obtain complete data as regards family history and other etiologic considerations. It is hoped however, that the essential data are sufficiently complete to warrant approximate conclusions. I have preserved a record of 350 selected cases of pulmonary tuberculosis seen in private practice during recent years to Jan. 1, 1898. These cases have been subjected to continuous observation and have been carefully recorded. The list does not embrace those with very extensive infection, and hence with admittedly unfavorable prognosis. Neither are there many included with incipient trouble. The cases, on the whole, may be said to represent fairly the average class of pulmonary invalids in Colorado, exhibiting as a rule upon arrival moderately extensive and rather active infection. I make no effort at this time to classify the cases or report results with sole reference to the tubercular involvement, as this has been done to some extent in a previous paper.¹ It is my object to analyze them simply with respect to the relation between the nervous manifestations and the tuberculous condition. Of the 350 cases, 220, irrespective of any ner-

¹ Boston Medical and Surgical Journal, Sept. 16, 1897.

vous complications, are found to have shown improvement in Colorado. By improvement, without any further explanation, I allude to the varying degrees secured of partial arrestment. About two-thirds of the cases, taken as they come, have done well through a fairly extended period of observation, not including those who improved temporarily and later failed through intercurrent disease, accident or individual indiscretions.

I have divided the entire list into five classes with distinct reference to the nervous condition:

Class 1 numbers 164, or nearly half of all the cases, and represents those who may be considered to be free from any nervous manifestation whatever. Of these, 111, or nearly 68 per cent., have shown pulmonary improvement in Colorado.

Class 2 numbers 98, or nearly one-fifth of the entire list, and comprises those possessing distinctly nervous temperaments, but not presenting definite neuroses. Sixty-four of these have done well. Percentage of improvement, 65.

Class 3 contains 39, or rather more than one-tenth of the whole, and embraces those exhibiting slight neuroses. Twenty-four, or 61 per cent., have improved. Nearly all of this class were subjects of mild neurasthenia.

Class 4 has 33, or less than one-tenth of the whole, and includes those presenting *well-marked* neurotic disturbances. Thirteen, or 39 per cent., have improved. These cases manifested the severer forms of neurasthenia, chiefly of the depressed type, and moderate degrees of hysteria.

Class 5, numbering 16, comprises those individuals with pronounced neuroses, not included in Classes 3 or 4, but in whom the pulmonary involvement was very slight or insignificant. Eight, or 50 per cent., have improved with reference to the tuberculosis. All of this class were markedly hysteric.

In commenting upon these results it is interesting to note that the percentage of improvement in those with distinct nervous temperaments without neuroses, is nearly equal to that obtained in those devoid of all nervous tendencies, and is slightly above the average of the cases as a whole. A rational explanation of this would appear to be that such persons are usually more keenly alive to the importance of their condition, and are therefore more susceptible to advice, and more conscientious in following instructions as to the details of their mode of life. While, speaking broadly, the phlegmatic temperament in tuberculosis, is more conducive to good results than the irritable or nervous. I have repeatedly observed the greater ease with which the active co-operation and obedience of the patient could be secured in those with moderately nervous tendencies. With such there is usually no occasion for argument or explanation. A simple statement of directions is frequently sufficient to entail implicit compliance. As the nervous disturbances increase to some extent, however, the balance is at once thrown to the disadvantage of the individual, and in case of marked neuroses, is exerted powerfully in preventing or retarding improvement. Such influence is well illustrated in Class 5, where the pulmonary involvement *per se* in each instance was so slight as to almost insure recovery.

The further consideration of these cases is limited to Classes 3, 4 and 5, as being the only ones concerning which it is profitable to enumerate statistics. In these three classes out of a total of 88, 45 are shown

to have improved, and 43 to have done badly. Of the latter number, however, 12 had gained for a time in Colorado, but subsequently failed for reasons not to be attributed properly to climate. In Class 3 a history of neurotic inheritance could be traced in 18 instances, or nearly half the cases. Of these 11 have shown pulmonary improvement. In Class 4, 21, or nearly two-thirds, have shown evidence of hereditary nervous influence. Ten of this number have gained in Colorado with respect to the tuberculosis. In Class 5 hereditary taint was strong in 12, or two-thirds of the entire class. Six have shown slight pulmonary or general improvement.

Of the 88 cases in these three classes, 51 present a history of an inherited nervous tendency, 13 may be fairly considered to be acquired, and 24 are in doubt, with no tangible means of ascertaining the facts.

Somewhat to my surprise the relative number of cases improved appears to be not materially different in those with inherited tendencies from the proportion obtained for the entire list, or for those without neurotic taint. It is important to note, however, that there has been a decided difference observed as to the *degree* of improvement, the gain usually being much slower and frequently more unsatisfactory in those with a history of nervous inheritance. I have occasionally recognized the pure acquirement of the nervous disturbance, or at least, its conspicuous aggravation to be developed from an intimate association with others afflicted with pronounced neurotic conditions. This has not been unusual in the case of husband and wife. I have not infrequently seen the development of nervous phenomena among several patients at the same resort attributable to the influence of a single subject of marked hysteria.

Thirty of the 88 cases with functional disturbance presented a history of inherited predisposition to tuberculosis. Of these 17 are also classed as subject to hereditary nervous influence. Fourteen of the 30 cases have done well in Colorado, despite the tubercular predisposition. Of the 17 cases, however, subject to *both* tubercular and neurotic hereditary influence, but 5 have shown improvement. The combination of the neurotic with the tubercular taint is apparently a factor of great prognostic moment.

The cases may be divided, irrespective of the degree of nervous disturbance, into three classes, with reference to the extent of pulmonary involvement. Without entering into a detailed explanation of the method of classification it is perhaps sufficient for present purposes to state that the first division includes those with comparative slight infection, the second those with moderate involvement, and the third those with extensive tubercular invasion.

Class A numbers 30, of whom 23 have shown pulmonary improvement.

Class B also contains 30, with 19 showing improvement.

Class C includes 28, of whom 3 have done well.

Attention is called to the fact that all the first class have gained except those with severe nervous complications; that more than half of the second class have improved, regardless of the degree or character of the nervous disturbance; and that, as illustrated in the third class, an extensive tubercular infection in neurotic individuals presents but slight hope of improvement.

As regards sex, there are 50 males and 38 females: The relative number of males is small in proportion

to the number in the entire list, from which these cases are selected. Of the 350 cases, 243 are males and 107 females. Thus only about one-fifth of the males are found to be subject to functional nervous disturbances, as compared with a little over one-third of the females. Twenty-two of the males with nervous disturbances, or 44 per cent. have gained, while 23, or over 60 per cent. of the females have improved. It is interesting to compare these figures with percentage of improvement obtained for males and females in the entire list. In the latter case the results are nearly equal, the female having a trifle over and the males a little under 63 per cent. These results as to the relative improvement in the sexes, singularly correspond with those obtained in a previous analysis of 200 cases in which the percentage for each sex was 69. The relatively greater gain made by the females with nervous tendencies over the males, is, I think, a striking confirmation of my former deductions concerning the influence of sex upon prognosis and management. I will quote briefly from my conclusions at that time:²

Despite obvious adverse conditions, and contrary to established conclusions, the female has responded to the favorable influence of the climate equally with the male.

Lest this be regarded purely as an instance of the strange fallacies of statistics, I offer several possible explanations in support of my results.

In Colorado, the question of success or failure in the effort to secure arrestment depends largely upon the ability of the individual to conform to a proper regimen of daily life, entailing for its greater perfection certain physical and mental requirements. These, I believe, are possessed to a greater extent by the female.

I cannot see that the separation from family is essentially harder for her to bear than for the male. On the contrary, she seems to adapt herself to strange conditions quite as quickly and as comfortably. While, in general, less opportunity is afforded for an existence in the open air, with judicious exercise, a life of more complete rest is assured, with perhaps many hours of sunshine. There is less chafing under restraint, less of the cares and responsibilities of life, less tendency to acts of imprudence, and, from my experience, more implicit obedience to detailed instructions.

It is but fair to add that the financial circumstances of the females in Colorado are in general relatively superior to those of the male. She does not usually seek change of climate unless proper provision has been made for her support.

If these premises are correct it is easy to understand how the female, although obviously more subject to neurotic conditions and more susceptible to nervous influences, nevertheless, in the face of the tubercular infection, is better equipped by virtue of her inherent and acquired tendencies, to withstand their unfavorable influences upon the course of the pulmonary disease.

It may be mentioned further that the improvement was more frequent in those who were relieved from domestic cares and responsibilities of children. As regards previous occupation it is enough to state that the gain in Colorado was decidedly more pronounced in those who had led sedentary lives. Two-thirds of these cases were Americans, the Irish and Hebrew races also showing a comparatively large number with nervous derangements.

With reference to the *character* of the *nervous* disturbance I am unable to effect a satisfactory classification. As the cases have been observed purely from a clinical standpoint, I will only allude briefly to the general nature of the neurotic manifestations, recognizing the difficulties of elaborating an arbitrary analysis. The cases are divided in a general way into

three classes, without reference to special symptoms.

The first includes thirty-four cases, presenting upon arrival evidences of considerable general restlessness with apparent exaltation of nerve forces. Twenty-one, or 64 per cent., have improved with respect to the lungs, while none have shown any perceptible increase of the nervous condition.

The second embraces twenty-eight cases exhibiting marked irritability of temperament with pronounced instability of nervous equilibrium. Ten, or 36 per cent., have shown pulmonary improvement.

The third includes twenty-six cases showing varying degrees of depression and hypochondriasis. Fourteen, or nearly 64 per cent., have improved.

A considerable number of the two latter classes have suffered aggravation of the nervous disturbances in Colorado, as will be considered later, either temporarily or corresponding to a coincident loss in the tubercular disease, or from purely external and easily attributable reasons. Three of each of these latter classes, however, are conspicuous examples of more or less continued exacerbation of the functional derangement from no well-defined cause.

These results are not incompatible with my general observations to the effect that in Colorado, as elsewhere, rather high degrees of irritability offer serious obstacles to a successful issue; that even considerable restlessness and excitation of temperament under appropriate management yields fairly satisfactory results; and that pronounced depression, while the type of neurasthenia exerting the most unfavorable influences upon the course of pulmonary tuberculosis nevertheless responds appreciably to the climatic change.

Insomnia and headaches were frequent special manifestations. Twenty-two suffered to a considerable extent from insomnia. Ten ultimately improved in this respect as well as in the lungs and general condition. In nearly every instance the gain has been slow and interrupted by periods of vexatious exacerbations of the sleeplessness. The majority of the remaining twelve showed no gain at any time, either in the lungs or the nervous disturbance. I have regarded the continued insomnia as of decidedly unfavorable influence upon prognosis; not merely from the loss of sleep and entailed exhaustion, but somewhat as an expression of the more profound nervous irritability with a general susceptibility to all depressing or exciting influences. Attention is called to the fact, although I am unable to give statistics, in this connection, that a very considerable number of pulmonary invalids obtain partial or complete relief in Colorado after having a more or less prolonged period of insomnia before arrival.

Fifteen of my patients were afflicted with migraine. Eleven have obtained relief, and have gained in other respects. In none of these cases however, have the headaches disappeared entirely. The degree of tubercular arrestment has been out of proportion to the neurotic improvement in this class. The latter has followed but slowly and unsatisfactorily a gain in the general strength. I have not sought, save in a few instances, to provide relief by attention to local causes.

Twenty-seven were victims of well-defined hysteria. Sixteen have shown pulmonary improvement, but remain subjects of the original neurosis, though some to a lesser degree on account of increased nutrition and suitable environment. Eleven had done poorly in every way, in eight of whom, as previously stated,

² Boston Medical and Surgical Journal, Sept. 16, 1897.

the pronounced hysteria was directly responsible for the unfortunate results.

An inquiry as to the *time of development* of the disturbances is perhaps of some interest. Of the 51 cases with hereditary influence the manifestation of the nervous condition was apparent in nearly every instance before the recognition of the tuberculosis, but was very frequently aggravated subsequently. Of the 37 in whom no family history of neurotic taint could be discovered, 10 may be considered safely to have exhibited rather pronounced symptoms before the onset of the tuberculosis but which became more marked later; 12 only after the development, or coincidently with it, and 15 unknown. Apparently the effect of the tuberculosis has been to render the pre-existing nervous disturbance more pronounced, to increase the susceptibility to such influences in those already predisposed by inheritance, and to provide the appropriate conditions for the acquired development, i. e., impaired nutrition, mental depression and auto-intoxication. Likewise, the previous existence of well-marked functional nervous derangement can but afford added opportunities for the development of tuberculosis, from the lessened resistance of the individual, and hence the increased receptivity of the soil to the agent of infection. Impaired general nutrition, while frequently a result, is also undoubtedly a potent factor in the causation of *each* diseased condition.

With reference to climatic influence, it may be stated that in almost no case were the manifestations of nervous disorder displayed for the first time in Colorado. Thirty-four cases suffered an aggravation in this State. Of these, 9 were rendered worse only temporarily and later improved satisfactorily in this respect. Twelve exhibited greater nervous disturbance coincidently with a corresponding loss of the tubercular condition, with increased impairment of strength and general nutrition. Seven presented exacerbations to be referred solely to sufficient external causes capable of application anywhere, as excessive dissipation, extreme burden of business cares, and unfortunate domestic relations. The remaining 6 became worse, from a neurologic point of view, in the absence of any apparent cause. Of the entire number (34) rendered more nervous, either temporarily or permanently after arrival, 19 died as a result of the pulmonary infection or have grown worse. The balance at the present time are showing varying degrees of improvement. Nine of these have made a remarkable gain in all respects, despite decided nervous disturbances.

Finally, of the 45 cases previously alluded to as having exhibited distinct pulmonary improvement, 39 showed an ultimate gain in the nervous disorder, and of the 63 cases showing no permanent loss, or doing well from the neurologic standpoint, 39 have improved with reference to the tuberculosis. Thus the results are:

Improved in both conditions	Cases, 39
Improved in tubercular but not in nervous condition. 6	
Improved in nervous but not in tubercular condition. 24	
No improvement in either.	19

The reasonable interpretation of this would appear to be, that the influence of the climate upon the nervous condition had been particularly advantageous in a large proportion of the cases, presumably by virtue of the pulmonary improvement secured with the increased nutrition. It is also evident that the climate

has been not unfavorable, to say the least, for the considerable number who either showed an improvement or no change neurologically, notwithstanding a progressive loss in the tubercular disease. These conclusions are of interest in view of the oft-repeated assertion that the co-existence of nervous manifestations contraindicates a recourse to the Colorado climate for the consumptive. The statement of the alleged aggravation of the nervous condition with the resulting unfavorable influence upon the course of the pulmonary disease, presupposes the hypothesis that improvement in the functional disturbance must precede arrestment of the tubercular infection, and at the same time advances the argument that the nervous derangement is of more essential consideration than the tuberculosis. It has been my observation that the nervous disturbances have diminished almost invariably in proportion to the degree of arrestment and the gain in the general strength. I am convinced that the majority of cases temporarily aggravated, or even developed early after arrival, are due in great measure to purely psychical influences, as enforced absence from family and friends, inability to immediate adaptation to strange surroundings, and previously accepted theories as to probable climatic effects. Such cases usually respond favorably later to rational and appropriate management. It should, however, be conceded, I think, that occasionally certain cases, especially those with strong inherent tendencies and severe manifestations, do poorly, particularly in the high altitudes of Colorado. These cases have been comparatively few in my own experience.

While the existence of pronounced nervous conditions in pulmonary tuberculosis constitutes a factor of grave prognostic moment in any location, it would seem that the climatic consideration of the tubercular infection per se should be regarded as of paramount importance. I would also insist that the especial significance of functional nervous disturbance in pulmonary invalids, should be to add further emphasis to the necessity of strict personal attention to details of management, environment and mode of life.

A FASCICLE OF CASES IN SUGGESTIVE (HYPNOTIC) THERAPEUTICS.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY H. S. DRAYTON, M.D.
NEW YORK CITY.

The American medical world has shown itself easily affected, as a rule, by the current of events, medical and surgical, in Europe. The experiments of Koch with tuberculin, of Klebs, Loeffler and Roux with antitoxin, and the various suggestions with reference to organic extracts—cerebral, testicular, thyroid, etc.—that have crossed the Atlantic have received a ready attention, in some cases developing into a wave of enthusiasm, and have found practical recognition in employment by many of our progressive medical brethren. I would refer merely to the disappointment that some have experienced in applying these more or less authoritative procedures, and remark *en passant*, that the wisest of us are subject to mistake occasionally through the very earnestness of our desire to wrest from old Mors one at least of his dreaded instrumentalities for human decimation.

In view of the readiness of the American profession

to entertain foreign advice in therapeutics it seems inconsistent with that quality of mind that one well accredited *modus* has not aroused interest enough to have it accorded a fair trial. I refer to the hypnotic procedure, or what is otherwise termed suggestive therapeutics. I am sure that all who listen to these remarks have learned something of hypnotism, and whatever the opinion they may entertain concerning it the fact is conspicuous that for several years this form or variety of psychologic medicine has had its hospital or dispensary establishments in Austria, Germany and France, and names of wide reputation, like those of Benedikt, Kraft-Ebing, Charcot, Delboef, Binet and Bernheim, are associated with it. Some American physicians have ventured to treat patients in this manner, but it would appear that with a few exceptions they were merely experimenting, and too distrustful of results to make the method a real part of their professional equipment. Some, too, I judge to be tender on the side of reputation, apprehensive that they might be regarded as giving sanction to "a superstition," as hypnotism was rather vaguely termed recently by the editor of one of our periodicals. I can scarcely believe that any one here gives heed to the medieval nonsense that sensational and unscientific writers offer to the unlearned public under the title of hypnotism or mesmerism.

Having given several years to the observation of the phenomena of suggestion I have come to the conclusion that the hypnotic state is consistent with the human physiology, and not to be regarded as determining a positive pathologic phase of either mind or body, although its induction may prove valuable as an aid in diagnosis. I have also reached the conclusion that in hypnotic suggestion we have at our hands an agency, the power of which is not fully realized, for the treatment of many forms of disease. In this statement I merely confirm the utterance of many writers from the time of Braid and Esdaile to the present.

I shall proceed to give some account of a few cases from my notes of those patients whose maladies commanded more than ordinary consideration. Let me assume that those present are sufficiently familiar with the common methods of inducing hypnosis, although for my own part I can not say that I have any particular method. One of my earliest experiences was recorded about nine years ago:

Case 1.—Frank S., a young man 28 years old, came to me with a history of epileptic attacks dating back to his fifteenth year. His physiognomy, the spare figure, angular hatchet face, dark, acne-spotted skin, dull expression, jerky, irritable movements intimated the chronic epileptic. As the attacks were frequent and often in series, he was incapacitated for remunerative employment. Then, too, the sequelae of a fit were becoming more severe and exhausting. He had been under the treatment of several specialists. Of one remedy he had taken \$400 worth, according to his father, with alternations of effect, but no decided improvement. Hypnotism had been suggested to the family of Frank, and I was requested to try it, as a *dernier ressort*. The young man consenting, a trial was made, and at the first interview sufficient control was obtained to warrant going on. My object, it may be unnecessary to say, was to impress the mind of the patient with a strong sentiment of opposition to the attacks, to reinforce his will in this behalf, and also to exercise as much personal control as possible over such of his habits as needed correction. He was a cigarette smoker, used strong coffee, and was prone to excess in eating, while in some respects his social doings needed amendment. The hypnotic control enabled me to be quite thorough on this side of his life.

The effects of this treatment exceeded my expectations. In a month he began to improve. The attacks occurred less frequently, and his health in every respect showed amendment.

After a time the treatment was given at irregular intervals, two or three weeks being allowed to intervene between a sitting, and when the patient's last report was made to me he had had no recurrence of the fits for three months, and had undertaken the transaction of business that required travel and exposure, a venture that previously would have been regarded by his friends as entirely out of consideration. In the course of my observation of this case there were developed certain phenomena that will, I think, be considered extraordinary, even if familiar with hypnotic cases. When the patient first came under notice his attacks occurred without warning. He would drop suddenly to the floor or ground as if struck by lightning, and on reviving a severe headache usually compelled him to rest a while, if not to sleep. During my treatment if an attack occurred he would be likely to come out of it with little more than a sensation of dullness that soon wore off. Twice the seizure occurred when I was within ready call, and then, to my surprise, I found that I could, in a few seconds, check the spasm and restore him to consciousness. On one occasion he fell to the floor in the presence of several persons, and was struggling violently when I came to his side. A sweep of my hands from the head to the knee suspended the convulsion and at my command he opened his eyes and rose to his feet, and within ten minutes was able to continue the business transaction he was engaged upon when he fell.

Case 2.—Mrs. E. M. of New Jersey, a woman of 50, of German parentage, vigorous and active, came to me with an account of prolonged attendance upon friends suffering from depressing fevers in spring time. Her appetite had failed, a distressing erythema had supervened rendering her unable to sleep or find repose in any direction. Such medical treatment as she had tried had but increased her distress and restlessness, and further endurance of the condition she declared unbearable. A strong, imperative nature, she seemed at first an unpromising subject for hypnosis, but yielded with comparative ease to the simple procedure of sitting in a comfortable chair and gazing steadily at the white knob of a door four feet or so distant. A brief manipulation of the head deepened the sleep into which she fell in less than ten minutes. Suggestions were made with reference to improvement of appetite, the recovery of nerve control and sleep. Two days later a second treatment of a similar nature was given, the lady reporting great improvement in general feeling, having slept well and relished her meals. This improvement was confirmed by the entire recovery of her usual vigor in the course of two weeks. This case is not offered as of an uncommon type.

Case 3.—Miss A., a lady of Boston, about 32, sent to me by her physician. She had suffered with an obscure cerebral malady for sixteen years; tracing it to nervous shock occasioned by a carriage accident. The focus of the disease lay in the situation of the right angular gyrus or anterior margin of the first occipital gyrus. From that point pain, almost constant when not under the influence of anodynes, radiated to all points of the head, being most severe in the course of the right optic nerve and of the great longitudinal sinus. A well-educated lady, with remarkable self-control, she described her symptoms with great clearness. It is an interesting confirmation of the doctrine of localization that her sight, especially in the eye opposite the supposed lesion, had gradually become impaired until she could not read ordinary print or distinguish objects thirty feet away. For relief of the pain, etc., she had visited specialists abroad and at home, and tried, she said, every kind of treatment—even to the late inventions of mental science and faith cure—and although at the suggestion of her last medical adviser she would now request me to try hypnotism she could feel little confidence in that. At the fifth interview Miss A. passed into the state of semi-trance, which state was repeated at the four or five succeeding interviews. The procedure in this case was simply to sit by the lady while she reclined upon a lounge, to hold her right hand in one of mine, occasionally to manipulate with great gentleness the forehead; meanwhile commanding her in a mild tone to go to sleep. With this semi-trance came entire relief from pain and abatement in the extreme sensitiveness of the scalp that had been an accompaniment of the malady. Besides the suggestion of relief from the old head misery, I advised the taking of small doses of gelsemium tincture and the application of hot-water compresses to the painful parts. The improvement in this case, as described by the mother and companion nurse of Miss A. was marvelous. After the third treatment she was able to ride out and endure with comparative comfort the noise and jars of the street. A year later she called at my office and reported that she had had but an occasional memory of her old affection, and were it not for her defective vision would consider herself perfectly well.

Case 4.—Rosa P., 33 years old, of Russian birth, dark com-

plexion, strongly bilious in temperament, well developed muscularly and possessing the powers of endurance usual to her race. The malady was peculiar in its effects; hystero-spinal in origin, with centers of reflex in the lumbar and cervical plexus, it was exhibited chiefly by great tenderness and pain in the lumbar vertebrae and flexor contractures of both hands and of the cervical muscles. The contractures of the hands, when she was brought to me were apparently permanent, any effort to open them resulting in an intense and painful paroxysm in which the clench was greatly increased and the arms participating in the flexure. The history of the case included ten years or more of hospital treatment and expert observation. The first attack, it was said, had come on unexpectedly when the patient was a girl of 15. She found her hands disposed to close and could not account for it. Belonging to an intelligent family, every available means were tried for her relief. In Russia, Austria, Germany and England she had been under treatment by specialists, Professors Benedikt and Krafft-Ebing among them, a variety of procedures having been undertaken, with but temporary relief, if any. Hypnotism had been employed, but only under repeated suggestions could the contractures be reduced for a brief space. Owing to some influence that was unpleasant in the hypnosis that was commonly produced, it had become objectionable, and the woman at first declined to submit herself to my treatment. However, after a brief interview she consented to a trial and passed easily into complete trance, and at command the hands slowly relaxed. On coming out of the sleep, which was profound, and without any transference of consciousness from one state to the other, the hands remained open and flexible, and continued so, enabling the woman to assist in household duties, etc., for three days, when they closed. Then she came again to me and was relieved of the contraction in the same manner. This woman remained under my observation and treatment for upward of three months, when she went south to live with a married sister. During this time her general health improved; the spinal myalgia, which, when I first saw her, prevented but brief rest in any position besides that of sitting upright, also yielded gradually to the suggestive influence. In a letter received fully two months after her departure from New York she stated that her hands had not closed, although she feared they might, because of her inability to apply to me for treatment. I should state in this connection that I had little expectation of doing the patient any permanent benefit because of her unfortunate family environment and lack of necessary care. A year later I saw her, she being brought to my office by her relatives, who wished to have her placed in some public or charitable institution. Her physical state had become much worse, but the poor woman, with eyes swimming in tears, held up her hands to show me that they were still open and flexible.

Case 5.—This case, of a widely differing nature, has a peculiar interest because of certain phenomena. Mrs. M., a strongly built, energetic brunette of 35 years, attending lectures at one of the medical schools of New York City, came to me in February, 1895. She recounted certain nervous experiences that interfered imperiously with the performance of anatomic studies. She was totally unable to dissect. On entering the room where cadaveric material lay she was seized with a strange nervous excitement that compelled her to withdraw immediately, and a distressing sickness followed, the effects of which usually lasted two or more days. The origin of her neurosis she believed to be this: Ten years or so before she came to New York, her father had died suddenly of apoplexy. She was not at home at the time of his death, and on returning was not immediately informed of it, although she knew that he had been very ill. Going into his room, she was surprised to find him lying silent and unresponsive. While she stood at the bedside gazing in speechless anxiety at him, there burst from mouth and nose a stream of blood. This unexpected spectacle terrified her so extremely that for weeks she was subject to hysterical fits and on the border of insanity. For years afterward visions of that blood-stained corpse and bed appeared in her sleep and in her waking hours. A woman of more than ordinary strength of purpose, she had striven against the terrible memory, and believed, until she attempted to use the scalpel, that she had nearly overcome the Nemesis of her life. She did not prove an easy subject for hypnosis, but at length entered the semi unconscious state—which, I may remark here, is claimed by some writers to be the true hypnotic condition as distinguished from the memeric or magnetic trance. As it might be, however, the suggestions for mental calm and self assurance in the performance of anatomic work and other duty were given, and a half dozen sittings of the kind were given. In the course of six weeks Mrs. M. advanced in the degree of self-control until she, as testified by one of her classmates, could

handle the instruments of dissection with coolness and facility.

During the winter of 1895-96 this patient reported to me at times, and to the effect that in pursuing her second year of study she had no trouble whatever, and that her recovery from the mental dread and solicitude of years was practically assured.

Case 6.—Mr. C. A., about 34 years old, by profession a lawyer; of excellent family. The history of the case is imperfect, and it is not necessary to dwell on what may appear to be very probable factors of etiology. Dr. F., who introduced the patient, desired to test the power of suggestion upon a mind confessedly under the influence of a delusion of fear that had continued for some years, and was becoming more accentuated. The patient, a clear-headed and rational man on other subjects, entertained a profound dread of being alone; would not venture to go from one room to another in his father's house without company, and it was only with great difficulty that he could be persuaded to go out of doors for a few minutes. When brought to my office he was in a state of excitement, with high pulse and pallid face. After some minutes of desultory chat, during which his nerves recovered a state of comparative calmness, I requested Mr. A. to sit in an easy-chair and to gaze as steadily as possible at the lens of a lamp used for laryngoscopic examinations, five or six feet distant; meanwhile I sat by his side holding his left hand in my right, one finger pressing upon the radial artery. At the beginning of the experiment his pulse ran quickly up to 120, and then gradually fell to 80, as nearly as I could estimate without consulting a watch. After sitting quietly in the attitude directed, I advised him to relax nerve and muscle as much as possible, giving himself up to a sense of ease and comfort. I gently stroked head and forehead, now and then repeating the admonition to be calm and comfortable. This was the nature of the first interview. At the next interview A. exhibited less excitement on entering my office, and a similar procedure was adopted as in the first, suggestions being added relative to the correction of his delusion. Repeated assurances were given of better self control, more steadiness of will, less attention to surroundings, more courage, spirit, independence, self-possession, etc. This line of suggestive treatment was continued at succeeding interviews until the fourth, when I commanded him to leave his residence at a certain hour in the afternoon, and walk unattended around the block. This was done, and the circumstance related to me by A. with considerable satisfaction. A few days later he came to my office without attendance. In the meanwhile he had gone with a friend to visit the Hagenbach collection of trained animals, an excursion of two or three miles from his home. The spell under which he had suffered appeared to be broken, for after two more interviews I was informed by his old physician that an extensive tour in Europe had been arranged on which he (the Doctor) was to accompany Mr. A., and that my fee for services rendered would be honored on sight. Since that time there have been no intimations of a return of the trouble, and Mr. A. is not the candidate for early confinement in an asylum that he had been considered only a few weeks before I first saw him.

REPORT OF A CASE OF RAYNAUD'S DISEASE WITH PATHOLOGIC FINDINGS.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY C. EUGENE RIGGS, A.M., M.D.

ST. PAUL.

HISTORY.

Mrs. M., age 64, weight 195 pounds, American, housewife. Had typhoid fever at age of 19, pneumonia at 53, measles, whooping cough, diphtheria, acute articular rheumatism at 50 years. Father died at the age of 76. Mother died at age of 71 of cancer of the breast. Has two sisters living, in average health, and one brother, whereabouts and condition not known. Two years before, the patient had noticed a peculiar numbness of sometimes one finger sometimes another of the left hand, which would last about half an hour. This continued at intervals for over a year. During this period the attacks of numbness came on about once a week, sometimes two mornings consecutively. She was, however, apparently well, when on the evening of Feb. 6, 1896, while going upstairs she was sud-

denly attacked with extreme numbness of the left hand and forearm, with a complete paralysis of motion and sensation in the same. She immediately went downstairs, when she found her hand as white as marble, friction giving her considerable pain. The hand remained white all night, and pain prevented sleep. Next morning the patient noticed the end of the thumb beginning to turn dark, and later other finger tips. The severe pain continued when not controlled by morphin, up to the date of admission to the City and County Hospital, Feb. 9, 1896.

On admission, it was noticed that the reddening was excessive, pulse 80 and somewhat irregular and intermittent, temperature 98.4. Finger tips of left hand were black, with exception of little finger, which was darker than normal. A dark streak extended up the dorsum of the hand between the thumb and forefinger to within three-fourths of an inch of the carpo-metacarpal articulation. There was loss of sensation and motion in the left hand, extending on the palmar surface to the metacarpo-phalangeal articulation, also loss of the sense of heat and cold over the same area. The arm was cold to junction of middle and upper third of humerus; veins of forearm and hand were very perceptible, giving the arm a peculiar marble-like appearance; the ends of the fingers of the left hand markedly shriveled on palmar surface.

At 11 P.M., February 10, on attempting to get up, she suddenly fell back in bed in an unconscious condition. The face became extremely dark, all respiration ceased, the pulse imperceptible except in carotids, where it could be barely felt. On auscultation, the heart could be only faintly heard. On the morning of February 11 two red areas appeared on the outer side of both thighs, which rapidly extended down the limb reaching the knee about 8 A.M., at which time a dark red spot was noticed on the heel of each foot, also along the external surface of the foot. At 8:45 the four outer toes began to turn purple and the outer aspect of the legs from knees down rapidly turned dark. The inner and anterior surface of the foot and leg was of a peculiar white color with markedly white veins coursing through the whole area. Patient complained of a very severe burning pain in the foot; the legs were cold to the knees. Apparent loss of motion and sensation in the limbs and feet. Patient was somewhat delirious and exceedingly restless. Tips of all the fingers of the right hand were of a dark purple color, but there was no paralysis of motion present in this member. In the right hand there was no development of the marble-like appearance preceding the reddened condition.

At the time of death local syncope had extended up the anterior surface of the left arm to the shoulder and the red color had extended up the dorsum of the arm, also in the axillary region down to base of ribs. The same condition existed in the right axillary region. Both legs were found to be perfectly rigid at 1 P.M., the flexors of the feet predominating. Marbled appearance of anterior surface of both limbs present after death, extending to about three inches above the knee. The brighter red condition on the inner side of the thighs changed shortly before death to a much darker hue. The right remained about the same as at 1 P.M. (Some edema of the lungs noted before death.) The slightly darkened spot which was noted on the left ear appeared perfectly normal after death, which was not the case with other portions of the body affected. Examination of the urine showed tube casts and albumin.

AUTOPSY.

Body very fat (weighing probably 200 pounds); rigor mortis well marked; postmortem lividity slightly marked over the back and under surface of the body. The thumb and all fingers of the left hand were black and gangrenous, the two distal phalanges being involved. On opening the calvarium the membranes of the brain were normal, except the pia mater, which was slightly edematous. The hemispheres of the brain were symmetric and of normal firmness. The vessels at the base of the brain showed the walls very slightly thickened, but no evidence of atheroma nor deposit of lime salts. On opening the thorax the pleural cavities were found free from adhesions; the lungs showed slight emphysema along the anterior borders, otherwise they presented no pathologic changes. The pericardium contained a small amount of clear straw-colored fluid. The heart was large and its walls infiltrated with fat. On section, a large post-mortem clot was found in the right ventricle entangled in the tendons of the tricuspid valve. The cavity of the right ventricle was somewhat dilated. The left ventricle contained some liquid dark blood; its chamber was markedly dilated and the walls near the apex very thin (about one-fourth of an inch), and consisted of fat and degenerated muscle. The mitral orifice was stenosed, admitting only the point of a finger. This was due to old inflammatory thickening, with deposit of lime salts in the anterior leaflet, and slight thickening of the posterior leaflet of the mitral valve. The left auricle was markedly dilated. The muscle wall of the heart was soft and flabby and showed marked evidence of fatty infiltration, with fatty metamorphosis of its walls, best shown near the attachment of the papillary muscle and in the ventricular septum. The blood-vessels of the heart were free from atheroma. The aortic valves showed no pathologic changes. The wall of the aorta was smooth.

Abdomen.—The layer of fat of the abdominal wall was enormously thick—2½ inches in places. An old irreducible omental hernia was found at the umbilicus, which was retained in place by peritoneal adhesion. The opening through which this protruded was about an inch in diameter; the intestines, especially the colon, were markedly distended and the mesentery and omentum were infiltrated with fat. The left kidney was slightly enlarged, its cortex narrow and the pelvis filled with fat. The capsule stripped easily, leaving the surface smooth. The vessels on the surface were much injected, contrasting markedly with the pale parenchyma of the organ, which showed marked evidence of nephritis. The right kidney was smaller than normal, due largely to narrowing of its cortex. The capsule stripped with difficulty, tearing with it portions of kidney, leaving a roughened surface. The cortex was very narrow and its surface uneven, showing here and there puckered areas and a few cysts. The spleen was somewhat enlarged (almost twice its normal size) soft and pulpy and on section very dark. The liver was soft and flabby, slightly smaller than normal and its surface yellowish gray. On section there was visible slight fatty infiltration, and bile-stained areas and dark liquid blood exuded from the severed hepatic vessels. The gall-bladder contained one large irregular cylindrical shaped calculus about one and one-fourth inches in length and three-fourths of an inch in diameter, and with it several small dark granular calculi were present. The stomach showed nothing

unusual. The pancreas were slightly smaller than normal and presented a narrowing near the middle. The head of the pancreas, on section, was darker than normal, but of the usual consistence. The uterus contained a small calcified sub-peritoneal fibroid tumor over the right cornua. The spinal cord was removed, also the median nerve of the left arm from the bend of the elbow to the hand. The radial artery of the left hand contained dark coagulated blood from a point extending about two inches above the annular ligament. The vessel wall was not atheromatous, and no thrombus was discernible. A noticeable feature of the case was the very dark liquid character of the blood all through the body.

Area of degeneration in Case 9.—Raynaud's Disease. Rigg's Path. Lab.

MICROSCOPIC FINDINGS.

The brain, medulla, segments, C 5 to D 10 of the spinal cord and portions of the median nerve and the anterior cerebral artery were received in the laboratory Feb. 11, 1896. The brain and medulla were injected with carmine starch solution and placed in formaldehyde sodium-zinc-chlorid solution. The cord and median nerve were placed in Müller's fluid. After three months the hardening of the cord and nerve was completed in alcohol, followed by embedding in celloidin, cutting and staining by Weigert's and Weigert-Pal methods. The brain and medulla were kept one year in formaldehyde, etc., solution,

when the medulla was embedded and cut in the same manner as the cord, the sections placed in Müller for a week and then stained by Weigert's method. Of the brain only a portion of the anterior cerebral artery was examined microscopically, after staining in paracarmine. The following are the findings:

Median nerve.—Transverse sections showed many unstained and unparently shrunken fibers irregularly scattered through all the bundles. Longitudinal sections showed almost all the fibers unstained and shrunken in irregular located segments; throughout the entire course of the several portions examined there appeared to be a simple parenchymatous degeneration. The proportion of degenerated to normal tissue appeared to be about three to two. Many rather large capillary hemorrhages were observed in the sections.

Area of degeneration in Case 9.—Raynaud's Disease. Rigg's Path. Lab.

Spinal cord.—Numerous transverse sections from segments C 5 to D 10 inclusive were examined. All segments from the tenth and seventh dorsal inclusive appeared to be perfectly normal, except for slight capillary hemorrhages scattered through the posterior median columns. Throughout all the other segments examined, from the sixth dorsal to the fifth cervical inclusive, the posterior median columns showed degeneration and numerous capillary hemorrhages. This degeneration first very faintly marked in the middle of the mesial margin of the left posterior median of the sixth dorsal segment column and gradually widening until in the seventh cervical the entire

column area on both sides was involved, was throughout most complete on the left side and in the crescentic area near the gray commissure. The latter area seemed also to be the seat of the most numerous capillary hemorrhages.

Long. section Median Nerve.

Medulla.—The lower half of the medulla, or at least all portions below the restiform bodies, had unfortunately been destroyed in the process of removal. Numerous sections taken from various levels alone failed to show any abnormalities whatever.

Cross-section Median Nerve.

Anterior cerebral artery.—Sections from various portions of this artery showed only a very slight thickening of its external coat.

SUMMARY.

It will be seen that this case had a typical beginning—local syncope, accompanied by much pain and associated with local asphyxia in the same limb. The typical venous marblings were present in both extremities and were very pronounced. The gangrene was of the mummy-like order, coming on without blisters, and the characteristic conical finger points with their shrunken and shriveled skin were most conspicuous. The local asphyxia of the left ear was well marked. We find also asphyxia developed in the right hand without accompanying or preceding local syncope. Death ensued before the latter development of the disease could appear.

The course of this case was however markedly different from the clinical description outlined by Grasset. He recognizes three periods: that of invasion, lasting from a few days to a month; that of development, with the accompanying pains and the commencement of gangrene; and that of elimination of eschars, extending over a period varying from ten days to ten months, the mean duration being from three to four months.

Cold, traumatism, renal and cardiac disease, atheroma, malarial and local poisoning, diphtheria, grippe, gout, organic and functional disease of the nervous system are so often associated with Raynaud's disease that they assume an etiologic value. At times, however, no apparent cause can be found, in which case the affection may be termed idiopathic. The theory generally accepted today as to the pathology of the disease is that held by Raynaud himself, viz., that there is a contraction of the small arteries, a tetanic spasm of nervous origin of the great sympathetic. He believes in a central origin because of the symmetry of the alterations.

In the above case the postmortem would point to a

renal and cardiac complication, though the marked cord lesion must not be overlooked, as a possible etiologic factor. Had this last any relation to the symptoms? From its character it must have antedated the onset of the acute symptoms, though not those first observed by the patient herself. The bilateral areas involved most were not those through which most fibers from the upper extremities pass, but those of the lower extremities, which were latest affected. The left column was more affected than the right and the symptoms were much more pronounced on the left than on the right side. The degeneration of the left median nerve was probably due to the condition of the left hand.

This case was referred to me by Dr. J. B. Brimhall of St. Paul.

THE STRESS OF MODERN CIVILIZATION AS A FACTOR IN THE CAUSATION OF INSANITY.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY FREDERIC S. THOMAS, M.D.,

PROFESSOR MENTAL DISEASES CREGGTON MEDICAL COLLEGE, OMAHA.
COUNCIL BLUFFS, IOWA.

In presenting a few thoughts upon this subject, I desire not to be exhaustive, but to present points merely for your consideration. The author does not claim the stress of modern civilization to be an exclusive factor in the causation of insanity, yet one which should not be dismissed without consideration. He believes that it is the most intimately associated with the formative period of life; that it is a causative factor in the development of neurotic temperaments. Instead of modern culture making the masses more resistive and better qualified for life's battle, in many instances, by reason of over-stimulation and faulty cerebral development, it tends to weaken the inhibitory qualities of the brain.

We are told that man in uncivilized life has but one source of pleasure, viz.: The gratification of his animal desires and passions. In his ultra civilized state, however, we find him possessed of another and higher condition—"a psychical existence—an intellectual life." This changed condition, the result of an irresistible evolutionary process, has transferred him from the field of ethnology to the domain of psychology.

A comparative study of mental alienation of both the uncivilized and the highly civilized races shows an unusually high per cent. of insanity in the latter. Omitting from our consideration epilepsy, trauma and their results, little or no insanity is observed among the unenlightened races. The higher the scale of intelligence and the more exacting the demands upon a people, the more likelihood there is apparently, of brain disease.

That civilization, and especially our modern civilization, should be a factor in its causation, though humiliating to admit, seems nevertheless to be true. Civilization itself is a departure from man's primitive condition. It is a development which gives to him a sort of dual existence and establishes within him an artificial standard. It has made new and extensive demands upon his energies; it has taken nutritive fluids out of their former and accustomed channels, that the brain might be supplied with the best vitalizing fluids of the body.

Anatomically we know the brain is made up entirely

of cells, fibers and ground substances, with the necessary framework of connective tissue, blood-vessels etc. If the processes going on in this structure be limited to its capacity, no harm is expected. If, however, the brain be subjected to the stresses of modern civilized life, a possible over-stimulation and consequent injury may result therefrom. Studying our subject from a histologic standpoint, we find that the nerve-cell belongs to the highest order of animal life aggregation. It possesses specialized nerve function and becomes a necessity in maintaining a proper relation between the infinite number of protoplasmic elements which compose the living animal.

We find that a mental process is the product of cell metabolism resulting from stimulation. The nerve fibers or processes from the nerve-cells, when bunched together in the great centers, must be insulated. There must also be communication between the cells of different and similar function, that the animal, as a whole, may fulfill its highest mission. We know that the muscle-cell, without its individual metabolism, would be useless, even though stimulated by an intact nerve-cell. The same can be said of a brain-cell. We know, in either case, perfect nutrition is essential. The latter being the most highly organized, would suffer the most from nutritive disturbances.

The immature elements of most recent development and highest in the scale reflect very early the disastrous effect of excessive or diminished nutrition. Considering the relatively large size of the cerebro-spinal system of a child at birth, the immaturity of its elements, and, in conjunction with this, the rapidity of growth in the first five years of life—from about eleven ounces at birth to forty ounces in the sixth year—we need not search further than environment for a possible production of early neuroses. Trivial causes produce profound impressions. Instability of the peripheral nerves, instability of the centers, lack of inhibition in the motor ganglion cells, accompany rapid development, diminished resistance and early exhaustion from undue stimulation. If this be true, will not the stress of modern civilization act most perniciously during the formative period of a human being's existence, by reason of undue stimulation, and from this reason will it not so weaken the nerve centers that the neuroses of childhood can but give place to mental enfeeblement or destruction in the adult?

"The prevailing tendency of modern civilized life is to over-stimulation of children. The tendency pervades our whole educational system. It permeates juvenile literature, it is manifest in childish recreations and has invaded the home. Such overstraining and stimulation of the nervous organism can not fail to cause harmful effects during childhood, and frequently produces neurasthenic and nervous temperaments in later life." The five senses were given to us by our Creator that the brain might take cognizance of His created energies. That we might approach nearest to His divine attributes, especially His omnipotence, the human brain was made of material most sensitive. Not that it could receive and record only the images about it by the aid of the reflected rays from the sun, or to analyze the sound waves, but also to receive and understand that which came to it through taste, smell and touch. In our environment of modern civilized life, the delicate structures of the ear and brain, which were so constructed as to recognize the tone, pitch and harmony of sound, are being

shocked by the discordant screams of the locomotive, the noise of the street-car with its clanging bells, the rumbling of the heavy wagons upon our stony pavements, the monotonous cry of the newsboys, the auctioneer or the fruit vender upon our street corners. By reason of all this, the beautiful and refreshing sleep of childhood is disturbed and the growing brain, which demands so much repose during this period of life, has been made to suffer therefrom.

The human eye, even more delicate in construction than any other organ in the body, no longer has reflected upon its retinal expanse the beauty of field and flower; the rolling landscape; the crystal streams with their green verdured banks, or the blue, starry vault above us, but is made to witness the revolting scenes of men maddened by their scramble for gold, or begrimed by the heat of toil in the busy marts of trade. The delicate olfactory cells which gather strength and delight from the pure air of the country, laden with the aroma of growing flowers and ripening grain, which gladden the heart of childhood, are dulled and blighted by the smoke and stench of our cities. Instead of this maddening whirl and strife of modern civilized life, could the eyes of childhood but be limited to see nature in her pristine beauty; the ears hear only the sweet carol of birds and the melody in the rustling leaves of the forest trees; then the sweet lullaby songs of mother would never cease to ripple harmoniously in the chambers of memory. If these things could hold a place in our modern civilized life, no one would dare say that the stress of modern civilization was a factor in the causation of insanity.

UTERINE HYPERESTHESIA.

Presented to the Section on Neurology and Medical Jurisprudence, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY EPHRAIM CUTTER, M.D.

NEW YORK CITY.

Included in this are uterismus, vaginismus, esophagismus, caputismus, pedismus, spinismus, crinismus and all pains that are reflex from the uterus, either touchal or experienced subjectively alone. To show that such cases are common, permit the following illustration:

Mrs. A. complained of swelling and pain in both ankles, called rheumatism, but there was no morphology of rheumatic blood. Intra-uterinism was found and treated with iodoform vectors. It was cured and also the ankle joint troubles.

Miss B. had vaginismus so that she had to be etherized for an examination, which revealed an anteverted and anteverted uterus. After the use of iodoform vaginal capsules the vaginismus was cured and afterward the uterine lesions of place were relieved by mechanical means.

Miss C., aged 30, could not swallow solid food. Bougies showed that there was no organic stricture of the gullet. Careful exploration revealed a verted and flexed uterus, relief of which was followed by the alleviation of the painful esophageal spasmodic actions.

Mrs. G., one of the best and bravest patients, was ill with a hyperesthetic swelling of the back of the left hand. I touched it gently. "Oh, doctor," screamed she, "don't touch my hand. I would rather you would knock me down." Rheumatism was looked for but its blood morphology was absent. I said that the womb must be at fault. She disputed it. But it was found to be hyperesthetic and retroverted. When these were relieved the hand got well.

Many women have complained of inability to wear shoes and walk, because their feet were so sore, and yet there would be nothing abnormal about the feet. But when their uterine hyperesthesia and lesions of place were relieved the feet were also.

A woman married and the marital functions were disturbed

by her screams of agony and by her collapse, so that every time connection was tried the family physician would have to be summoned. On one occasion—not marital—this physician gently touched her spine in examination and she fainted. This case was seen in consultation. Further history not known.

Calling on one of my uterine cases once, I was met with the exclamation, "Oh doctor, please excuse the disorder of my hair, as I can not bear the touch of comb or brush to my head."

Mrs. G., above alluded to, sometimes had hyperesthesia of the whole body, so that at night she could not bear the weight of bed and night clothes and was obliged to be nude.

What is pain, which is the main element of hyperesthesia? It is something invisible, imponderable, subjective, felt. It needs the medium of nerves which, fully paralyzed, abolish pain, as in etheric anesthesia. After many years' study the writer is inclined to take the ground that pain comes from a partial paralysis of the nerves. Smite with a birch switch and you inflict pain, but with a crowbar you can smite without pain because you kill the person smitten or completely paralyze the nerves near to or remote from the injury. It has seemed as though the uterine hyperesthesias unexplained by organic changes, arose because its stock of nerve force, dynamis or constitutional energy had been so exhausted by the lesions of function or place that the uterine nervous system was partially paralyzed and squealed in pain when it acted. Also that it steals from other parts of the body, whose nerves thus robbed of their share of dynamis squeal also. It is reasonable to expect that its relief must come by restoring to each autonomic organ its normal amount of nerve force by abolishing, if possible, the physical conditions of its cause.

As an inventor of pessaries, I have had to contend with uterine hyperesthesia as the greatest bane to their use. Hence what is said here is the outcome of a fight with conditions that have baffled gynecologists for ages. It is useless to use a pessary or, if you will allow the personality, the Cutter pessaries, unless the hyperesthesias are removed. There are exceptions but they are few. I beg, entreat, implore and beseech that this should never be forgotten. If so, we shall hear less of the hard things said against the use of pessaries. It is a pity that these instruments should suffer because of the disobedience to this rule—a pity, as otherwise more patients would be cured and less opprobria cast on the profession, which it really does not deserve.

I try to utter these moritural words with truth and soberness. There is a conventional disregard of uterine hyperesthesia. Lately I saw a report where a gynecologist examined and treated the females in a large insane asylum and found two-thirds suffering with hyperesthesia and uterine disease. Systemic works glide over this subject. If I am mistaken I shall be glad to be corrected.

A physician told me once that he had never dared use a uterine sound. It would be but guess work to diagnose internal hyperesthesia without it. I think the Simpson sound too big. I like a rigid steel sound, platinum plated, the size of a No. 1 vesical sound. From what I hear, I judge that uterine hyperesthesia is ignored as subjective, as a whim and as unworthy of attention.

As a rule, women bear pain well. Prof. H. L. Hodge of Philadelphia, used to say in his clinics, "When a woman complains, in ninety-nine cases out of a hundred she has a good reason for it. If you are not smart enough to find out what is the matter with her, say so, and never blame her as a malingerer."

Through patients I have heard of women doctors

who used a cold and unanointed speculum in hyperesthetic virgin vaginas. This shows that woman's inhumanity to woman exceeds that of man to woman. I have been called rough by male physicians, but I never had a lady patient say so. Hence I invoke women practitioners to be specially on the watch for "uterine hyperesthesia," and never to undertake to use a pessary without first having removed the hyperesthesia, if present.

The "irritation" of Professor Hodge I call hyperesthesia. He taught its existence as a neurosis without any appreciable organic lesion. But the writer is of the opinion that it exists along with organic lesions, which lesions are curable without the knife in some cases. I have had extra uterine fibroids contemporaneous with mammary gland fibromas and hyperesthesia, that have been diagnosed as cancer, and yet they have been removed by diet and the principles here laid down, after the irritation of Hodge had been removed.

The metabolic changes in health are not confined to normal tissues and organs, but they are applicable and are going on in unhealthy organs or tissues. If healthy organs or tissues can be hyperesthetic it is more likely that unhealthy organs or tissues will be because they have less vitality. To illustrate: on Dec. 13, 1896, I was poisoned at an autopsy, on the proximal end of the first phalanx of my left little finger. Today there is a dermal tuberculosis, whitish, leprous, red, with flattened hard elevations pitted at the top.¹ If anything, the diseased is more hyperesthetic than the sound skin, as unconscious touchings which are unnoticed by the sound skin are hyperesthetic. In fact, galvano-caustic hurts more than on the sound skin. Do not then let the terms "irritation" and "hyperesthesia" be buried in Prof. Hodges' grave and mine own.

Debts of gratitude are due to McDowell, Atlee, Kimball, Sims, Thomas and other surgeons, for opening new fields of gynec diagnosis which to Professor Hodge were unknown; but the knife is not everything. Nor do women exist for laparotomy sections alone. The knife should be used in cases of hyperesthesia as a last resort. For example, a lady said that a distinguished surgeon (whom I love) decided that she needed an immediate laparotomy of an ovarian cyst, seated where she had hyperesthesia. Had he made a vaginal examination he would have found a case in question. Under the principles laid down here and diet, the ovarian and uterine hyperesthesia have disappeared.

A good test is the laying on of hands, practised, I am told, some 2600 years B.C., and now in Germany. Place the patient in supine posture. Put the right forefinger on the hyperesthetic uterus and the left palm over the hyperesthetic ovary. The dynamis thus conferred removed the pain in the last case in a few minutes. I should add that I have not been able to detect the cyst. In 1873 I learned from patients rubbing my well knee that the pain in my broken knee was relieved, when otherwise it had its own way.

Iodoform vaginal gelatine capsules have been found very useful. I have used them since 1862. Though it works most admirably, the bad odor of iodoform is its greatest objection, otherwise I place it at the very head of all medicines, opium not excepted. Aristol comes next to iodoform and is used the same way. It is a wonderful medicine. It ought to be a household

¹ Nov. 28, 1898, cured.

remedy for cuts and burns. I tried it last summer. When rolling, at our seaside cottage, after most had left, a barrel on to a piazza, my hand slipped and a rusty nail projecting from the supporting board penetrated the fascia of the palmar surface of my right wrist. It burnt. It bled. Immediately the whole hand was in hyperesthetic agony. Aristol powder was laid on, then absorbent cotton and a bandage. Shortly the pain subsided. Without suppuration, the wound healed kindly in a few days. The scar remained some time longer and now is gone. I can not help thinking that if uterismus is relieved as my manismus was, it is easy to see why women express their feelings of relief during its application. I think this bit of experience not out of place here as showing the power of aristol to relieve intra-uterine hyperesthesias. To make the vectors, mix aristol into pill mass with molasses which is a little thick, cut into proper size, apply mass to pin-headed wires three inches long that screw into a wire handle like a uterine sound, mould into cylinders with a spatula on a glass plate. Iodoform is used in the same way. Once one application of an iodoform vector to a $3\frac{1}{2}$ -inch hyperesthetic uterine cavity in one month's time was followed by a reduction to normal size. In this case the wife of a foreign ambassador at Washington was enabled to resume her diplomatic receptions, at which previously she had fallen insensible on the floor. Amitol is a new substitute for iodoform which I have found quite useful. Its whiteness, cheapness and odorlessness are recommendations. Gelatine vaginal capsules have long served a good purpose. It should be remembered that the meaning of our subject is a loss of nerve force. Restore this and sustain nature's biologic efforts is the way to cure. Those illustrative cases could be given, but as the injunction is to "write short papers," this must suffice.

120 Broadway.

THE SURGERY OF CAMP WIKOFF.

BY N. SENN, LIEUT. COL. U. S. V.

CHIEF OF THE OPERATING STAFF WITH THE ARMY IN THE FIELD.

(Concluded from page 1355).

ERYSIPELOID.

Erysipeloid, an acute inflammatory affection of the skin, described by J. Rosenbach, is a disease of the skin not often recognized. It is usually mistaken for erysipelas. The parasite was described by Rosenbach more than ten years ago, but it has never been classified. Attempts to cultivate it have failed so far. This disease is met with usually among persons engaged in the handling of fish and meat, that is, cooks and butchers. It is attended by very slight constitutional disturbances and its local progression is slow as compared with erysipelas. The starting point is generally a finger, where infection takes place through slight surface defects or a puncture. It consists, pathologically speaking, of a subacute inflammation of the lymphatic channels of the skin. The affected skin presents a bluish color instead of the bright red seen in erysipelas. Another and perhaps more important characteristic sign in the differentiation between erysipeloid and erysipelas is the appearance of the margin of the inflamed area. In erysipeloid the shading from diseased into healthy skin is gradual, the line straight, in erysipelas abrupt and the margin presents well-marked fan-shaped projections instead of a straight line. The thickening of the skin by infiltration in erysipeloid is slight and the only thing the patient complains of is a sensation of burning or smarting. The disease travels in the direction and against the lymph-current, so that when the point of infection is some distance from the tip of the

finger, this is reached in time by extension of the inflammation downward from the point of infection. The disease travels slowly, it usually takes a week or more before the inflammation reaches the base of the finger when infection takes place anywhere near its tip. The lymphangitis seldom if ever extends beyond the elbow joint. The infection may extend from one finger to another when the inflammation travels in a distal direction. The skin soon returns to its normal condition behind the zone of infection. A case of this kind came to the surgical ward for treatment.

Case 41.—Patrick J. M. McGeoch, age 24, kitchen employe, presented himself September 9, complaining of a burning, smarting pain in the right index finger, which commenced four days ago. Over the radial side of the affected finger, opposite the middle joint, is a small abrasion covered by a thin adherent crust. The skin half as far as the tip of the finger and an inch above this point is slightly swollen and presents a bluish-red color. The discoloration is most marked on the dorsal side. At the proximal margin of the zone of inflammation the diseased gradually shades into the healthy skin, both in regard to color and swelling. Patient is able to follow his occupation. The case presents all the characteristic signs of Rosenbach's erysipeloid. An alcohol compress with oiled silk over it was applied. In three days the inflammation had extended to the base of the finger while the distal portion, the seat of the disease when the patient first came under observation, presented a normal appearance, the skin being somewhat shrivelled by the action of the alcohol application.

AFFECTIONS OF THE RECTUM, ANUS AND ADJACENT TISSUES.

Rectal affections in some form were very common among the returning troops from Cuba. It is fair to presume that some of the soldiers were the subjects of a mild form of hemorrhoids when they entered the service, but it is equally certain that none of them were affected with fistula or abscess. To show the disproportion of rectal disease between the recruits who applied for enlistment and the soldiers returning from the field, I will state that of 10,000 applicants examined in Camp Tanner last spring the following rectal affections were noted: Hemorrhoids, internal, 2; external, 219; inflamed, 1; fistula, 1; prolapsus, 2. I attribute the prevalence of rectal diseases among our patients in this camp to the following causes: 1, intestinal affections contracted in the camps and Cuba; 2, improper food; 3, the relaxing effect of a tropical climate; 4, frequent exposure. Few of our soldiers escaped diarrhea or dysentery. The irritation of the rectal mucous membrane could not fail in many instances to produce a catarrhal proctitis. The inflamed mucous membrane became permeable to the passage of pathogenic microbes, which so constantly infect even the healthy rectum. The loose pararectal connective tissue, under the influence of general causes, became more susceptible to infection, it is therefore not astonishing that we should have found so many cases of perianal, perirectal and ischiorectal abscesses and their consequences, fistulae. Inflammatory affections of the rectum play also an important etiological rôle in the development of hemorrhoids. We found in a number of cases a direct connection between an antecedent rectal inflammatory affection and the subsequent appearance of hemorrhoids. The intense teneismus which attends catarrhal proctitis and dysentery causes muscular changes and lesions of the mucous membrane which often become the principal cause of pararectal inflammation and hemorrhoids.

PARARECTAL ABSCESS.

Under this head I will report all cases of suppurative inflammation in the vicinity of the anus and outside of the rectal wall that have been operated on in Camp Wikoff. In all cases the suppurative inflammation pursued a very rapid course. The pain, as a rule, was intense, and fluctuation could be felt distinctly in the course of four or five days. In high-seated paraproctitis the general symptoms were usually severe, a high temperature and a rapid bounding pulse. It was in these cases that the affection assumed the most progressive form. The abscess contents were always fetid, otherwise presented

the usual appearance of pus as found in acute abscesses in other localities.

Case 42.—Robert F. Stanley, age 22, Troop G, Ninth Cavalry, colored. Perianal and ischio-rectal abscess. While in Cuba had diarrhea for eighteen days—August 27 to September 1—had chills and fever. Reached Camp Wikoff September 3, on which day he had pain about the rectum before and during defecation and on sitting down. He was admitted to surgical ward September 8. By careful palpation a small area of circumscribed induration as large as a pea could be felt on the right side of the sphincter muscle and about one-third of an inch from the surface. This swelling could not be detected from the rectum. Pain was greatly increased under pressure. A small incision was made and about half a dram of pus escaped. The little cavity was washed out with peroxid of hydrogen and carbolized water and loosely packed with a strip of iodoform gauze. As an external dressing a hot moist antiseptic compress was used and held in place by a T bandage. Immediate and almost complete relief followed the operation. On the ninth, the temperature rose to 100 degrees F., on the tenth to 101. The pain was intense and referred to the opposite side of the rectum. September 10, a fluctuating swelling could be felt from the perineum and the rectum. The abscess bulged externally as well as on the rectal side. The patient was again anesthetized and the abscess incised through the perineum to the left of the median line. A large quantity of extremely fetid pus escaped. As the undermining was extensive two counter-openings were made, one below and one above the first opening. Two fenestrated rubber tubes were employed in draining the large cavity. The abscess was washed out with carbolized solution and peroxid of hydrogen, and the moist antiseptic compress applied. The pain was relieved at once and the discharge after the operation slight. No tendency to further undermining, on the other hand all indications point to an early and permanent healing of the abscess cavity.

It is in cases like these that practitioners so frequently make a serious mistake by postponing from day to day opening and draining of the abscess. If we had deferred the operation for another day or two the abscess would have ruptured into the rectum and would have led almost inevitably to the formation of an internal or complete fistula. The horseshoe fistulae following cases of ischio-rectal abscess, so frequently found in any of the large surgical clinics are the best proof of the necessity for early operative interference. The rule should be to open such abscesses early, from the external surface, and if fluctuation can not be felt from this direction but from the rectum, the tissues on the side of the rectum can be tunneled with forceps after making a superficial incision, until the abscess cavity is reached. The surgeon must so conduct the treatment that the formation of a fistula can be avoided, and this can be done in nearly all, if not all, cases in which the abscess is opened before it ruptures into the rectum.

Case 43.—Alva J. Vananken, age 27, Troop K, First Cavalry. Perirectal abscess. On his last day in Cuba the patient had a mild fever and diarrhea; the latter persisted fifteen or sixteen days. For the last ten days has had a throbbing pain in the post-anal region. An abscess found and opened in the median line, between the anus and coccyx. Under ether anesthesia the abscess cavity behind the rectum was freely opened with the Paquelin cautery, taking the fistulous opening in the median line as a guide for the incision. The cavity was thoroughly disinfected and packed with iodoform gauze, over which the usual moist dressing was applied. Rapid healing of the cavity by granulation.

Case 44.—Robert Sylvester, age 24, Company G, Fourth Artillery. Has been ill with typhoid malarial fever while in Cuba. Returned from Cuba on the steamer *Leona*, and reached Camp Wikoff about September 1. Soon after his arrival he noticed pain on the left side of the rectum. The pain and tenderness increased rapidly in intensity. September 7, he was admitted to the surgical ward and the operation was performed without anesthesia three days later. At this time the abscess was prominent on the side of the anus and the overlying skin presented an inflammatory blush. Fluctuation very distinct from the rectum as well as from the surface. The abscess was opened by a single incision and tubular drainage established, as the incision was large enough to serve for drainage. After disinfection of the cavity and packing it lightly with iodoform gauze, a moist antiseptic compress was applied. The patient was very weak at the time the operation was performed, but gained sufficiently in strength in a week to warrant his transfer to a hospital in Philadelphia.

Case 45.—Joseph Barret, age 28, Third Infantry, Company G. Ischio-rectal abscess. About the time of the surrender of Santiago had general malaise, fever, vomiting and diarrhea for which he has since been on the sick list. Several days ago he began to experience pain in the rectum which has increased steadily since, and at the time he was admitted to the surgical ward the ischio-rectal abscess had opened spontaneously on the right side just within the anal margin. General health much improved. On August 31, under chloroform anesthesia the abscess cavity was distended with peroxid of hydrogen for the purpose of ascertaining its exact size and location. A grooved director was inserted into the fistulous opening and used as a guide in laying open the abscess cavity freely with the knife point of the Paquelin cautery. The abscess cavity was disinfected and packed loosely with iodoform gauze over which the moist compress was applied. He improved rapidly after the operation and a few days later was transferred to a hospital in Boston.

Case 46.—William Head, age 20, Eighth Ohio Infantry, Company G, enlisted two and a half months ago. Admitted to the surgical ward with a history of malarial fever and dysentery in Cuba, followed by ischio-rectal abscess which discharged itself near the anal orifice on the right side. Discharge continues profuse. The peroxid of hydrogen test was applied to ascertain the extent of the abscess cavity which was found to extend high up into the ischio-rectal fossa. Owing to the marked anemia and general debility a counter-opening was made lower down and thorough drainage secured, in place of opening the abscess cavity freely with the Paquelin cautery. Chloroform was used as an anesthetic. The general and local conditions improved promptly after the operation.

FISTULA.

The spontaneous rupture of a pararectal or ischio-rectal abscess into the rectum is generally followed by the formation of a fistula. If the abscess communicates with the rectum its existence can be surmised from the intermittent discharge of pus and local symptoms which refer to the rectal lesion. An internal fistula of such an origin is often made complete by the abscess finding eventually an external outlet somewhere in the anal region. An external fistula caused by the opening of a pararectal abscess not infrequently becomes complete by the destructive process penetrating the rectal wall. I have long ago abandoned the probe in differentiating between an external fistula and a complete one. Injection of peroxid of hydrogen into the cavity under pressure makes a positive diagnosis at once. If the fistula is external the abscess cavity becomes tense, if complete the peroxid foam enters the rectum and will escape from the anus. The probe is only used after the test has made the diagnosis and then only as an aid in performing the necessary operation. In diagnosing the existence and location of an internal fistula the rectal speculum is of the greatest importance. Rectal fistula will be less frequently met with when the profession as a whole recognizes the importance of early operative interference in cases of pararectal abscess. In my surgical work in Camp Wikoff only two cases of rectal fistula presented themselves for operative treatment.

Case 47.—Lieut. G. W. Goode, Troop I, Ninth Cavalry. Hemorrhoids and fistula. He was admitted to the surgical ward August 24. He has been almost habitually constipated, and has been much in the saddle. He knows of no definite preceding illness to account for present condition. He has had much pain and bleeding on defecation, pain persisting for an hour or two after. Examination reveals large internal and external hemorrhoids and an incomplete internal fistula following the rupture of a post-rectal abscess, into the rectum through the middle of the sphincter muscle, posterior side. The abscess cavity, the size of a walnut, was freely laid open upon a grooved director with the knife point of the Paquelin cautery. The incision was carried directly backward through the median line. The hemorrhoids, two in number, affecting the posterior segment of the anal ring were removed by clamp and cautery. The abscess cavity was loosely packed with a strip of iodoform gauze. The rectal tampon remained for two days. The patient made a rapid recovery and was able to leave the hospital September 13. The agonizing pain attending and following each bowel movement disappeared immediately after the operation.

Case 48.—John M. Boyd, age 29, Troop G, Third Cavalry, enlisted four months ago. Admitted to the surgical department of the General Hospital August 27. His health was

good until he went to Tampa, June 8. At that time he suffered from diarrhea which was persistent, but did not prevent his doing duty in the saddle. For the past five weeks and following a severe pain in the rectum which continued several days, he has noticed a discharge of pus from the rectum. The pain did not disappear entirely after the abscess ruptured into the rectum and was always aggravated during defecation. August 28, under chloroform anesthesia the sphincter ani was dilated, the internal opening was found, the cavity distended with peroxid of hydrogen, external counter-opening made by the aid of the grooved director and the intervening tissues divided with the Paquelin cautery. Iodoform gauze packing and dry dressing. The internal opening in this case was just above the sphincter muscle, the abscess on the right side of the rectum. Rapid healing of the abscess cavity.

HEMORRHOIDS.

A large number of hemorrhoid cases came to the surgical ward with the desire and expectation of receiving the benefits of a radical operation. I am satisfied that only a small percentage of those affected were willing or prepared to be subjected to an operation. Some of the cases examined peremptorily declined to receive treatment knowing well that the results would put one claim for pension beyond their reach. In my capacity as operating surgeon of the camp I was very anxious to curtail the list of pensioners of this war by performing operations for surgical affections which, if left alone, would furnish a just claim upon the Government. On the whole, I found the colored soldiers much more willing than their white comrades to be benefited by surgery. They proved themselves worthy of their hire in the hospital as well as on the battlefield. Too much can not be said in praise of our colored soldiers. They showed a staunch faith in their doctors as well as their commanders, and were ready at all times to follow their advice as well as the commands of their officers. Nearly all of the hemorrhoids operated on showed pathologic appearances which demonstrated their recent origin. In a very large percentage of cases the first manifestation of hemorrhoidal condition was preceded by intestinal disturbances, diarrhea or dysentery. Fortunately, I had two Paquelin cauteries at my disposal as soon as the operating tent was opened. As I said in the beginning of this paper, my instrumentarium at first was a very scanty one. Instruments, however, began to come, day after day, and finally I had an excellent supply, including a number of cases for special work. The absence of a proper pile clamp from the outfit of the surgical ward at the outset, necessitated the use of something as a substitute. This was found in a curved hemostatic forceps. Except for its lightness, and therefore comparatively inefficient grasping power, this answered the purpose admirably. In fact, the facility and accuracy with which the hemorrhoidal swelling could be clamped and isolated, the small space required for its use, and its general convenience and ease of handling as compared with heavy clamps, now in the market, led to the devising by Major Adams of Chicago, of a hemorrhoid clamp similar to the forceps used, but so constructed as to obviate the defects of weakness and imperfect grasp found in that instrument. The use of the forceps as a clamp has demonstrated that the amount of pressure and crushing exerted by the old-fashioned instruments are unnecessary and uncalled for; also that there is no need of ivory plates to prevent the transmission of heat through the metal of the forceps to the underlying mucous membrane, as in no instance was any ill effect observed from this cause. Another advantage of the narrow blade forceps has been demonstrated in the absence of any hemorrhage whatever after operation. The new clamp has blades with a serrated grasping surface 5 cm. long, curved on the flat, the width of the blades closed is 9 mm., their thickness 6 mm., beveled away from the upper to the outer edge for 1 mm. The object of the bevel is to allow of the operation of the cautery with the least possible contact with the metal of the clamp, to avoid heating. The blades come into contact at the point first, so that uniform pressure is exerted

the whole length of the blades when closed, and the hemorrhoid can not escape its grasp at the point, as often happens with the ordinary clamp.

The handles are arranged like those of a needle forceps. With one exception the hemorrhoids were removed with the knife point of the Paquelin at a dull red heat, after clamping the swelling at its base. The hemorrhoid was first grasped with a dissecting or hemostatic forceps, when the base of the cone elevated to the desired extent was grasped and clamped with the forceps and the mass outside of the grasp of the instrument shaved away with the cautery. The operation of removal was always preceded by dilatation of the sphincter. The patients were always properly prepared for the operation the day before. The rectum was thoroughly cleared out by the administration of a cathartic and irrigation. The last enema was given on the morning of the operation. As a rule, two or three seizures were made. After dilatation of the sphincter the hemorrhoidal swellings were located and grasped with forceps so that the work of clamping and cauterization could proceed without interruption. Care was exercised in every case not to remove too much tissue; due allowance was given for subsequent contraction. The anal region was shaved and prepared in the same manner as for operations in other localities. One of the principal sources of pain after operations for hemorrhoids has been the protrusion and swelling of the cauterized surfaces. For many years I have suc-

TRANSVERSE SECTION OF BLADES.

Hemorrhoid clamp, devised by Major Adams.

ceeded in preventing this very painful post-operative complication by resorting to drainage and rectal tamponade. This method of dressing rectal wounds after this operation is not sufficiently known and practiced. Those who have not tried it might entertain a fear that it is a source of distress rather than comfort. Quite an extensive experience with this method of after-treatment enables me to make the unqualified statement that the rectal tampon, properly applied, is well borne by the patients and makes the use of anodynes superfluous. I never administer opiates after operation for hemorrhoids. The rectal tampon not only obviates unnecessary pain, but it also is almost an absolute protection against secondary hemorrhage and more than this, it provides for free rectal drainage and constitutes the best possible dressing for the cauterized surfaces.

When I first used this tampon, I was under the impression that it was something new, but I learned later that Mitchell Banks had used a very similar contrivance before. The tampon is made by taking a piece of rubber tubing eight inches in length and inserting into it a glass cylinder three-fourths of an inch in diameter and about 2 inches in length. The glass tube is placed where the gauze tent is tied over the rubber tubing for the purpose of furnishing a support to the string with which the gauze tent is tied upon the tube and to insure patency of the tubular drain. The rubber tube should project well over

the glass cylinder on the rectal side. The gauze tent is made of one or two layers of iodoform gauze. After completion of the operation the tent is carefully folded and the upper portion covered with vaseline. The tube is then inserted into the rectum to the depth of three or four inches and the space between the tent and tube packed with strips of iodoform or plain sterile gauze. After the required amount of packing is inserted the tampon is pushed in the direction of the rectum sufficiently to bring the pressure above the grasp of the sphincter muscle. In doing this the projecting mucous membrane and what may remain of the external hemorrhoids are completely reduced. The gauze outside of the anal orifice is then wound around the tube and forms a part of the external dressing. Over the gauze a wide ring of absorbent cotton is applied and the whole retained in place by a T bandage. The tampon should remain for 24 to 48 hours.

Rectal tampon. Rubber tube 20 cm., glass tube 8 cm.

In removing it traction is made on the gauze tent sufficiently to bring the packing within easy reach when it is removed before an attempt is made to extract the tube. After the removal of the tampon the patient should be given a laxative and after this has acted the cauterized surfaces now minus the eschar are protected by applying carbolated vaseline or some other antiseptic non irritating ointment. I have made it a rule to keep the patient confined to bed for at least a week, still better two weeks. The cases of hemorrhoids operated upon in this camp with very few exceptions have been men whose general health was much impaired, yet in every case the wounds healed quickly and in the most satisfactory manner under the treatment outlined above.

Case 49.—M. J. McNulty, age 31, Company D, Sixteenth

Infantry, enlisted six months ago. Has had small hemorrhoids for two years, causing inconvenience only after heavy drinking. In June, while in Florida, bleeding at stool occurred for the first time. Since he suffered from malarial fever and diarrhea during the Cuban campaign, he has suffered from profuse bleeding on defecation. September 3, under chloroform anesthesia, three hemorrhoidal swellings were removed.

Case 50.—George Morton, age 47, sergeant Ninth Cavalry, Troop A, colored, has been in the service ten years and seven months. Had dysentery two months ago, since then has suffered from pain in the rectum and bleeding with each evacuation of the bowels. August 26, under chloroform anesthesia, three hemorrhoids, partly external and partly internal, were removed by clamp and cautery.

Case 51.—Jesse Donaldson, age 30, Troop M, Ninth Cavalry, colored, enlisted three months ago. While in Tampa, patient suffered from malarial fever and diarrhea, the latter continued for three or four days. Has not been well since that time. Since August 1, he has been much inconvenienced by a hemorrhoidal affection which developed recently. Operation performed under chloroform narcosis, September 2. Three internal hemorrhoids, two posteriorly, one at upper right quadrant, were removed in the usual way by clamp and cautery.

Case 52.—Claude F. Hall, age 23, Company G, Sixteenth Infantry, had hemorrhoids about four years ago, but not so severe an attack as the present. Recovered without operation. Has been in the service since the 17th of September, a year ago. Following an attack of malaria and diarrhea in Cuba, he has been suffering from hemorrhoids for the past six weeks. He has no bleeding, but the hemorrhoids have been protruding constantly and are very painful. September 7, under chloroform anesthesia, three internal hemorrhoids were removed in the usual manner by clamp and cautery. They were located respectively in the posterior right and left quadrant.

Case 52.—James Jervis, age 19, Company K, Thirty fourth Michigan Infantry, enlisted three and a half months ago. Had diarrhea two weeks, before leaving Cuba. Has had much pain and bleeding with movements of bowels since. Never had rectal trouble of any kind before. August 31, under ether anesthesia, two internal hemorrhoids were removed.

Case 53.—Ora Keithley, age 23, Troop M, First Vol. Cavalry, first suffered severe pain from hemorrhoids in July, when on duty in Cuba. He had had previously an attack of rheumatism from exposure to rough and wet weather and sleeping on wet ground. On September 7, three hemorrhoids, partly external and partly internal, were removed.

Case 54.—Horace Carden, age 24, Troop M, First Vol. Cavalry, has suffered off and on for three years from hemorrhoids, the present attack was not preceded by any bowel complaint or other illness. Has had no bleeding, but much pain and itching. Operation under chloroform anesthesia, September 8, when three internal hemorrhoids were removed.

Case 55.—Silas McGovern, age 28, Troop A, Ninth Cavalry, colored, has been in the service three years. Patient was admitted to the surgical ward September 3. One week ago, directly following an attack of diarrhea, he noticed pain in the rectum on defecation. The mucous membrane of the rectum protruded with each stool. Day after admission the patient was chloroformed and three internal hemorrhoids were removed. The appearance of the swellings indicated their recent origin. The mucous membrane was in a state of catarrhal inflammation. The posterior half of the anal ring was principally affected by the hemorrhoids as well as by the catarrhal inflammation.

Case 56.—Joseph Etter, aged 19, Troop I, Ninth Cavalry, colored, has suffered for the past two months from hemorrhoids which he believes were brought on by heavy lifting. Since the supposed "strain" he has experienced severe burning pain with each movement of bowels and profuse bleeding. Pain has been persistent after stools for several hours. September 8, under chloroform, three large, dark-blue hemorrhoids were found, one on right and left side posteriorly, and one on anterior left quadrant. The swellings were removed as usual by the use of clamp and Paquin cautery.

Case 57.—Lee Shanks, age 26, Troop A, First Vol. Cavalry, has been in the service three months. He has been suffering from hemorrhoids for the past month with no illness preceding. He has had much pain after defecation, but no bleeding. Under chloroform three external hemorrhoids were removed, September 2. One of the swellings occupied the posterior wall of the rectum to the right of the median line, one to the left of the median line posteriorly, and the third in the anterior left quadrant. The hemorrhoids were disposed of in the usual manner.

Case 58.—Corporal Samuel H. Edwards, Troop C, First Cavalry, began to suffer from profuse bleeding on defecation the

latter part of July, following an attack of diarrhea while on duty in Cuba. Pain has not been severe at any time. September 10, under chloroform anesthesia, four very large internal hemorrhoids were removed by clamp and cautery, two from either side of the median line anteriorly. The hemorrhoids in this case were distinctly venous, the swellings being composed of ectatic veins almost exclusively.

Case 59.—Henri Meuronval, age 43, Company F, Second Volunteer Engineers, has suffered from hemorrhoids since puberty, with exacerbations at varying intervals. Recently much pain and bleeding. Examination under chloroform, September 11, revealed a large internal venous hemorrhoid on the right side, which, owing to the fact that the Paquelin cautery did not work that day, was treated by ligature. Before the silk ligature was applied, the mucous membrane at the base of the swelling was incised. An ulcer as large as a dime was detected directly over the sphincter muscle in the median line and posterior surface. This ulcer was evidently the remote result of a retroanal abscess which occurred a year ago. Since that time the pain during and after defecation has been much more severe. Besides stretching the sphincter, preliminary to ligation of the hemorrhoid the superficial fibers of the sphincter muscle were divided, carrying the incision through the center of the anal ulcer. Rectal tamponade as usual. The pain was relieved promptly by the operation.

Case 60.—Capt. Nat Phister, age 44, Company G, First Infantry, has had attacks of hemorrhoidal distress in 1888 and 1893 but not so severe as at the present time. He has suffered severely with present attack since August 19, the exciting cause being constipation. The suffering was much aggravated by a long ride in the saddle which he was compelled to take while the hemorrhoids were prolapsed. Since that time he has had severe pain and constant muco sanguinolent discharge, necessitating the wearing of a diaper. Under chloroform a medical operation was performed September 8, consisting in the removal of two large hemorrhoids, largely external, and affected by extensive excoriations. The operation afforded the desired prompt relief.

Case 61.—John M. Dixon, age 40, Company B, First Infantry, had an operation seven years ago and had no trouble after that until about the first of August, when after a prolonged attack of dysentery he began to suffer with prolapse of the rectum. He has been in the service seventeen years and when last attack occurred he was in Cuba. He reached Camp Wikoff September 13. He has been greatly debilitated by the dysentery, and the prolapse occurs whenever he assumes the erect position or attempts to walk. Has much constant distress with pain, smarting, itching and occasionally bleeding. Under anesthesia operation was performed September 14. A large hemorrhoid was removed from the posterior aspect of the rectal wall and a vertical strip of mucous membrane by clamp and cautery. A smaller swelling and strip of mucous membrane were removed from the left quadrant in a similar manner. Rectal tamponade. Strict directions were given that the patient should be kept in the recumbent position for at least a week.

Case 62.—James Skinner, age 28, Troop H, Ninth Cavalry, colored, was sick in Cuba with dengue fever, about twenty days, beginning about July 14. Recovered only partially from this before (beginning August 14) he had an attack of malarial fever lasting fifteen days. During both attacks he had poignant diarrhea. During the early stage of malaria the hemorrhoids appeared, with much pain, prolapses and bleeding. On September 13, under ether narcosis, two internal hemorrhoids were removed from the posterior wall of the rectum middle line, and the right posterior quadrant. Patient's health much impaired, anemia marked.

Case 63.—John Holloman, age 22, Troop B, Ninth Cavalry, colored, has always been in good health until the latter part of July, when he had diarrhea for three days while on duty in Georgia. Since then he has had pain on defecation, prolapse of the bowel and sensation of incomplete evacuation, but no bleeding. September 15, the patient was etherized and four internal hemorrhoidal masses removed by clamp and cautery.

Case 64.—Abraham Hill, Company C, Twenty-fourth Infantry, colored, has been in the service twelve years. About eight years ago he had hemorrhoids, which were operated on successfully. For the past three months, while on duty in Cuba, he has been suffering great pain on defecation and slight bleeding. Rectal prolapse at stool, always easily reduced. Has enjoyed fair health and attributes the attack to the heat and dampness of the Cuban climate. Operation under chloroform anesthesia performed September 16. Three very large internal hemorrhoids, located posteriorly and laterally, were removed in the usual way by the clamp and cautery.

The cases related above are instructive in showing what kind

of surgery may be expected among soldiers who have participated in a campaign in a tropical country, subject to its indigenous diseases and debilitated by its climate, improper food and exposures. The results obtained must also counsel the military surgeons to practice their art not only on the battlefield, but also for surgical lesions caused independently of wounds and so often overlooked in the field hospitals. I have to record only two deaths, and both patients were operated on in the wards of the general hospital, being too weak to be transferred to the surgical ward. Both of them were low with typhoid fever complicated by large metastatic abscess, in one the parotid, in the other the submaxillary being involved. One died the next day after incision and drainage, the other on the third day. I am satisfied that many of our cases of phlegmonous and typhoid abscesses would have died without timely and thorough surgical interference. In many of the other cases, more especially hemorrhoids and fistula, the operations performed will restore the men, with the aid of proper general treatment, to their usual condition, and cut them off from the pension list. In all aseptic cases the wounds healed by primary intention, the best possible proof that good surgical work can be done in an operating-tent in the field, and with very limited facilities for carrying out aseptic precautions. Since writing the above paper, a number of interesting surgical cases have been operated on in the surgical ward, which I will now report under the head of

MISCELLANEOUS CASES.

Case 65.—Edward J. Hill, aged 23, Troop I, Ninth Cavalry, colored, enlisted three months ago. Painful tetanoid spasm following gunshot wound of heel. About two months ago, while in Tampa, accidentally shot himself through the left heel with a Krag-Jorgensen carbine (30 cal.). The bullet passed transversely in an oblique direction through the os calcis. There is no evidence of comminution of the bone, the contour being well preserved and the surfaces smooth. While under treatment for the wound, he thinks he contracted "rheumatism in both loins." He has suffered twice from painful tetanoid spasm of the gastrocnemius, the attacks lasting about three hours, then subsiding as suddenly as they came on and leaving the leg painless and useful. He entered the hospital August 28, suffering from a third attack which lasted more than twenty-four hours, subsiding suddenly during the night after his admission. The gastrocnemius is firmly contracted, the heel raised, and any attempt to extend the foot aggravated the pain. No tenderness of heel or scars.

Case 66.—Wade H. Bell, age 21, Company A, Sixteenth Infantry, enlisted May 23. He has been troubled with varicocoele for the past two months. It causes soreness and pain on walking any distance, incapacitating him for guard duty, and he believes the difficulty is gradually increasing. He first noticed the varicocoele when he was sick first with malarial fever for five days. Had three such attacks. Veins nearly the entire length of the cord much dilated and tender on pressure. Operation by excision under chloroform anesthesia, September 5. Transverse suturing of the external wound to shorten the elongated scrotum.

Case 67.—James H. Hebel, age 21, Battery 3, Fourth Artillery, enlisted three and a half months ago. Purulent ophthalmia and perforative keratitis. On Saturday, August 27, he felt sensation of a foreign body in the right eye. The next day profuse purulent discharge. On examination August 31, the conjunctiva was found intensely swollen and vascular, discharge of pus profuse, eyelids swollen and edematous, pupil contracted; beginning of ulceration near the center of the cornea; beginning pannus, intense photophobia. There is no trace of gonorrheal infection. The treatment consisted of frequent cleansing with boracic acid solution and application of ice. Atropin could not be secured for three days. After that time it was used in sufficient strength to dilate the contracted pupil. In spite of all that could be done, the corneal ulcer perforated and the anterior chamber of the eye was partially evacuated. At this time the patient obtained a furlough and, on his own responsibility, undertook the journey to his home in Chicago. He was advised to place himself on his arrival under the care of Professor Hotz.

Case 68.—George Slate, age 24, civilian. Habitual dislocation of the left shoulder joint. This is the sixth time during the last two years the accident occurred. Patient probably under the influence of liquor when injured, as he does not

know how it happened. Became aware of the dislocation on waking up in the morning. Several contusions on other parts of the body were discovered. Dislocation of head of humerus downward and forward underneath coracoid process of the scapula. On request of the patient chloroform was administered, and the luxation reduced very easily by extension and rotation. The arm was immobilized by a Velpeau bandage. Accident September 15, reduction the following forenoon.

Case 69.—Peter Hansen, age 32, farrier, Troop L, First Cavalry, fell from stumbling horse September 15, in such a way that he struck the ground with his left shoulder. He has been unable to raise his arm since. Carries affected shoulder lower than the opposite one. Pain and circumscribed tenderness over the clavicle about an inch from the acromio-clavicular articulation. Patient somewhat obese, so that the distal side of the clavicle can not be readily traced. Fracture of the clavicle near the acromion process was diagnosed, although no distinct displacement could be made out or crepitus elicited. Arm supported in a mitella.

Case 70.—Edward Consan, age 24, Troop I, Ninth Cavalry, colored. Enlisted four months ago. Admitted to the surgical ward September 7, with swelling and extreme tenderness of anterior surface of the left tibia. Previous diagnosis of osteomyelitis had been made. No history of injury. The swelling is most marked over the central portion of the shaft of the bone. The onset of the disease, the location and character of the swelling and the nocturnal exacerbations of the pain left no doubt as to the syphilitic nature of the periostitis. Inquiry develops a history of primary syphilis four years ago. Has had secondary eruptions and mucous plaques, etc., and at the present time there is hyperplasia of the lymphatic glands in all the principal accessible regions.

Rest in bed, elevation of limb, hot, moist, antiseptic compress and the internal use of potassic iodid in 15 grain doses, four times a day constituted the treatment that was directed. Under the iodid the pain and tenderness diminished, as well as the swelling. A few days after his admission a small fluctuating swelling could be felt in the center of the inflamed area, but as no pus was expected the use of the knife was refrained from. This superficial central softening is often seen in gummatous swellings and will disappear under the treatment the patient is receiving now. If absorption of the liquid contents of the fluctuating swelling does not take place, tapping and washing out with a 5 per cent. solution of carbolic acid will be resorted to.

Case 71.—L. J. Torney, age 24, Troop D, Sixth Cavalry, has been in the service two years and four months. Pressure paralysis of radial nerve. While in Cuba was in the hospital three days for chills and fever. He joined his command after his discharge from the hospital and was quite well for three weeks, when suddenly he became unconscious and was afterward wildly delirious and had to be tied to a litter for safe transportation. During this trip he lost the use of the extensor muscles of the right hand. The paralysis remains complete, otherwise the patient is in fair condition, although occasionally the temperature rises to 102 F. The patient is not confined to bed. The paralysis of the musculo-spinal nerve was undoubtedly caused by pressure during the transportation on the litter. Massage and electricity were advised.

Case 72.—Thomas Clemens, age 21, recruit, Twenty fourth Infantry, enlisted two months ago. Hydrocele of the cord. Came to the surgical ward for diagnosis September 16. Six months ago, while in the act of lifting a heavy box, was taken rather suddenly with pain in the right side of the scrotum. In a few days a swelling developed, the size of a hazelnut, which has remained. The swelling is tender to the touch and is connected with the cord about an inch above the epididymis. The swelling is circumscribed and fluctuates distinctly. It was diagnosed as a hydrocele of the cord.

APPENDICITIS.

It is somewhat astonishing that, in these days of appendicitis rage, of the many thousand soldiers who have landed at Montauk, not one case of appendicitis came under my notice that would have justified an operation. We would naturally expect that among such a large body of men, almost all of them at some time during the last five months the victims of intestinal affections, the appendix should have claimed its good share of disease. The climate, the diet, the previous intestinal affections contracted in Cuba, should have, according to our ideas of the nature of appendicitis, combined in exciting the disease. But such was not the case. The profession is well aware of the fact that surgeons who can see nothing

else but appendicitis in cases in which the patients complain of pain in the right iliac fossa, have performed laparotomy, and these cases were not few in number, where as an excuse for their error in diagnosis, they have completed the operation by removing a normal appendix. Of the three cases of supposed appendicitis sent to the surgical ward, in only one the diagnosis proved correct, and this case was such a mild one that an operation was not deemed justifiable. One proved to be malaria, and the third typhoid fever.

Case 73.—Charles W. Dyer, age 19, Company K, Seventh Infantry, has been in the service only six weeks. He was taken sick September 11, and was transferred to the surgical ward three days later. The attack commenced with a chill and some fever, the following day pain in the right iliac region set in. Bowels constipated, no vomiting, loss of appetite. Had a similar attack a year ago, from which he recovered in a few days. On his admission to the surgical ward there was slight tenderness over the appendix and cecum, no tympanites and no palpable swelling or muscular rigidity, temperature only a degree above normal. Catarrhal appendicitis was diagnosed, complicated probably by a similar condition of the cecum. Rest in bed, liquid diet and ounce doses of equal parts of castor oil and sweet oil, four hours apart, until the bowels move, constituted the treatment, under which the patient recovered in a few days.

Case 74.—James Reid, age 21, Company I, Seventh Infantry, has been in the service three months. Was admitted to the surgical ward September 1, with the diagnosis of appendicitis. The clinical history, as well as his condition at the time of admission, warranted a change in the diagnosis from appendicitis to typhoid fever. The temperature was erratic, showing malarial complication, but the curve from day to day showed the typhoid part to our satisfaction. The tongue was brown and dry with red tip and margins. Pulse 100 and temperature at that time varied from 101 to 105 F. Abdomen tympanitic and great tenderness in the right iliac fossa. Numerous rose spots appeared on the abdomen next day. Under appropriate treatment the fever subsided gradually at the end of the third week of his illness. The great tenderness in the right iliac fossa undoubtedly led originally to a wrong diagnosis, but it simply indicated in this case deep typhoid ulcers in the lower portion of the ileum.

Case 75.—Martin G. Normao, age 27, Seventh Infantry, Company C, enlisted three months ago. On leaving Santiago he began to feel bad with headache, anorexia and malaria; became worse; lost sleep and complained of pain in the stomach; most severe on left side under costal arch; bowels constipated, tongue large, flabby, with indented margin. Spleen markedly enlarged. At times has had pain in cecal region, which disappeared promptly after the administration of a laxative. Under quinin this patient improved rapidly.

STRICTURE OF THE URETHRA.

Case 76.—H. J. Ewing, age 54, Company A, Ninth Infantry, has been in the service twenty-eight years. Admitted to the surgical hospital September 12, and transferred the next day to a hospital in New York. Has suffered from stricture of the urethra for a number of years. Exploration with the olive pointed bougie reveals a small and tight stricture in the membranous portion of the urethra. The cause of the stricture is a fall upon the perineum he sustained in 1864. Denies venereal infection of any kind. Of late years he has had attacks of stoppage of the urine. The stream is small and mic-turition frequent. Patient transferred to New York for treatment.

Case 77.—Frank Hugh Banks, age 20, Ninth Cavalry, Troop D, enlisted three months ago. Has had several attacks of gonorrhea, the last, two months ago. The stricture for which he was admitted to the surgical ward September 1 involved the membranous portion of the urethra, was an old one and was much improved before he was transferred on the 8th to his command. By careful and prolonged attempts a No. 8 bougie passed the stricture. The treatment consisted of gradual dilatation.

Case 78.—T. C. Mark, age 29, Thirteenth Signal Corps, enlisted three months ago. Has stricture of the urethra dating back to gonorrhea two or more years ago. Examination made September 14 shows stricture half an inch back of the meatus A 14; another just in front of the scrotum admitting A 12. Gradual dilatation was commenced, but patient was transferred to a hospital in Boston two days later for further treatment.

The few cases of gonorrhea, syphilis and stricture observed in Camp Wikoff speak well for the morality of our army.

ADDITIONAL CASES OF FRACTURE.

Two cases of fracture of the long bones occurring in men belonging to the Cuban Army are of interest in showing impaired nutrition as one of the causes of delayed or non-union.

Case 79.—Hillyard H. Felder, age 44, packer, not enlisted. Five weeks ago, in Cuba, fell from a freight wagon; jumped to save himself and landed on his feet in a small hole, twisting his legs. He sustained a transverse fracture of the right tibia about an inch above the base of the inner malleolus, and a transverse fracture through the middle of the external malleolus. He came to the surgical ward September 14, the left limb in lateral splints, the right in plaster of Paris bandage. None of the fractures of the right leg have united, and there are no signs of formation of provisional callus. Fracture of left fibula united with some deformity. Patient is over six feet in height and very much emaciated. Plaster of Paris bandage renewed on right limb; no dressing for the left one. Operation for non-union of fracture of tibia advised as soon as the patient's general condition is improved.

Case 80.—John Coleman, age 28, Irish, stevedore, employed at the dock, Montauk harbor. Admitted during the afternoon September 12, to the surgical ward. While handling lumber was struck on right side of face by a crowbar handle set in motion by the slipping of a wrench. The accident occurred an hour before his admission to the hospital. The patient was unconscious and very restless. Right side of face swollen. Two small wounds had been sutured before he entered the hospital. Exophthalmos of right eye caused by retro-bulbar hemorrhage, divergent strabismus and dilatation of pupil, which does not respond to light. Free hemorrhage from mouth; no hemorrhage or serum discharge from either ear. Through the swollen part of the cheek the malar bone could be distinctly moved and crepitus was distinct. Pulse 60. No paralysis. Fracture of the malar and superior maxilla with extension of lines of fracture through the base of the skull was diagnosed. On the second day the patient's condition was very much improved but toward evening a rapid rise in temperature led to a careful search for the cause of the fever. Professor Delafield was called into consultation and found a right lobar pneumonia.

Since leaving the camp I have been informed by Dr. Greenleaf that the pneumonia terminated in a typical crisis at the usual time, and that the patient is recovering rapidly from the injury.

Case 81.—Charles Lubbae, age 44, German, engineer. Fracture of the clavicle. A week ago while at work as engineer on the *Vigilancia*, was struck on the right shoulder by a falling plank producing a fracture of the clavicle at the junction of the outer with the middle third. The fracture was oblique, the internal fragment displaced upward and forward and some overlapping. Reduction and Sayre Velpeau dressing. Patient was transferred the same day to New York.

ADDITIONAL CASES OF GUNSHOT INJURIES.

Case 82.—Peter Carr, aged 40, sergeant Company F, Sixteenth Infantry. In service 16 years and nine months. Was wounded July 2 before Santiago. He fell down at once on receipt of the injury, and on trying to arise found that the left leg was paralyzed both as to sensation and motion. He was carried to the First Division Hospital where the wound was dressed and he remained four days, thence to Siboney where he staid three days before being taken on board Hospital Ship *Relief*. He was landed from the *Relief* at Governor's Island, has had a furlough of thirty days and on Sept. 16 reported for duty at Camp Wikoff, entering the surgical hospital Sept. 18. Examination shows a vigorous looking man with partial paralysis of left leg. There is a scar on the left side of the back 2½ inches from the median line and on a level with the second lumbar vertebra. This marks wound of entrance of the ball, there is no wound of exit. The patient says the wound healed very promptly with only slight discharge; further that four weeks elapsed before he could rest any weight upon the leg, but he has been improving ever since and can now walk with a cane. There is marked wasting of the extensor muscles of the left thigh and marked impairment of sensation of the left foot and leg. He says that occasionally the leg gives way in walking, especially if the toe strikes something above the level of the ground. He can not raise it when flexed and states that with much walking the knee swells. There has been no impairment of function of bowels or bladder and no priapism.

In this case the ball probably passed transversely producing contusion of the cord and bruising the roots of the spinal nerves very near their origin; it is probably lodged where it will do no further harm. The man says the X-ray was used twice but the result of examination was not reported to him.

Case 83.—B. F. Frazier, age 24, Company B, Twenty fourth Infantry, has been in the service eleven months. While in action July 1, before Santiago, he received a wound of the right hand, the bullet entering the web between the index finger and thumb, passing through the ball of the thumb and making its exit at the base of the adductors over the anterior row of carpal bones. No bone injury. The wound was packed with gauze. The wound of exit healed in two weeks, the wound of entrance has never closed completely and has discharged from time to time a small quantity of serous pus. The patient was admitted to the surgical ward July 15. Examination with the probe revealed the presence of a small metallic body. During the preparation of the hand for operation a small triangular fragment of metal was washed out of the fistulous opening. Under anesthesia next day the wound was again explored and the probe passed to a point underneath the scar of the wound of exit, detected another piece of metal which was removed by incising the scar, when a fragment of lead much larger than the first was extracted. On scraping out the fistulous tract with a small sharp spoon shreds of gauze were removed. The bullet that inflicted the injury must have been a deflected one, as otherwise no fragments of lead would have been left in the wound. The gauze undoubtedly belonged to the packing used at the first-aid dressing. The wound was dressed in the usual manner; no provision for drainage was made, with the expectation that it would heal speedily by primary intention.

Case 84.—John Marke, age 22, Troop D, Sixth Cavalry, enlisted five months ago. He was wounded in the charge on San Juan Hill, July 1. The bullet cut the margin of the upper posterior edge of the right ear, entered the scalp one inch above and one and a half inches behind the right external meatus, and emerged from the scalp three inches in a direct line from point of entrance, probably making a superficial groove in the external surface of the occipital bone. The patient says he was taken to Key West while in an unconscious condition, in which he remained two days. July 6 he was operated on, the wound being laid bare by a curved incision and a small piece of bone is said to have been removed. The wound healed in a month. Scars healthy and not sensitive to pressure. He complains now of attacks of throbbing pains from back of head to eyes, three or four times a week; the attacks last sometimes half an hour. He does not complain of vertigo or disturbance of any of the special senses. Whether the symptoms are purely of a neurotic nature or whether they depend on the injury must be determined by future observation. Potassic bromid was prescribed.

From the above report I have excluded minor cases that were treated as out-door patients or inmates of the surgical ward not of sufficient interest to have any material bearing on the subject of this paper. This communication has been written for the special purpose of pointing out to the profession, and more especially to the military surgeons, the nature and sphere of surgical work in field hospitals at the end of a war. This completes my surgical work of this war, and I return to civil life grateful to the authorities and my colleagues for the kindness and many courtesies I have received at their hands.

General Hospital, Camp Wikoff, Sept. 17, 1898.

THE KRAG-JORGENSEN BULLET-WOUND.

BY LIEUT.-COL. VALERY HAVARD.

CHIEF SURGEON U. S. VOLUNTEERS.
BRIDGEPORT, CONN.

At my request, Dr. Mariano Ojuna, surgeon in chief of the military hospital at Santiago de Cuba, kindly sent me, on Aug. 19, 1898, some notes which I offer as a small but interesting contribution to a very important subject. Dr. Ojuna regretted his inability to prepare a more elaborate report, being at the time exceedingly busy in superintending the transfer of the sick and wounded to the Spanish transports. But first a few preliminary remarks.

He states that 541 wounded—43 officers and 498 men came into the military hospital for treatment. Of the killed he makes no mention. As this hospital was the only available one, we may infer that all the wounded really *hors de combat* were admitted to it.

On the other hand, according to the official Spanish report, the casualties were as follow: Killed, officers 17, men 107; wounded, officers 59, men 556; missing, officers 7, men 116.

As this report includes the few navy casualties which occurred before the destruction of Cervera's fleet, and likewise accounts for a certain number of slightly wounded men who never entered the hospital, the discrepancy between it and Dr. Ojuna's figures is sufficiently explained. We may note, incidentally, that the above statistics show a proportion of casualties of about 10 per cent.—1.7 killed and 8.3 wounded. On our side, the total casualties at San Juan Hill were about 13 per cent.—1.86 killed and 11.14 wounded. The ratio of killed to the whole number struck was one-fifth among Spanish, and one-seventh among American troops.

In order to justly appreciate the results described by Dr. Ojuna, it should be remarked that the hospital where all these cases were treated is an old building without adequate water-supply and without sewerage, the excreta being emptied into a large pit; it was also at that time crowded to two or three times its normal capacity: in a word, it appeared beyond the possibility of good sanitation. To this we may add that proper food and several important medicines were scant and became entirely exhausted. Dr. Ojuna's notes, freely translated, are as follow:

"... Since the beginning of hostilities, 45 wounded officers were admitted to this hospital; 26 have been discharged cured and 7 died; of the others, only 2 were serious cases: one with comminuted fracture of the left tibia, already united and nearly well, the other with fracture of the same bone but loss of over a centimeter of substance nearly throughout its thickness; in this case a cure is also expected, in time.

"All these wounded, with hardly an exception, never had any fever. They were mostly treated with solution of corrosive sublimate, iodoform, iodoform gauze and absorbent cotton; that is, with antiseptic dressing, changed only every two or three days according to indications. There were fractures of various bones, such as humerus, ulna, radius and those of the carpus, tarsus and metatarsus, but I did not observe a single case of arthritis, nor the slightest complication. As an interesting fact, worth special mention, I did not have to perform a single amputation among all the wounded officers.

"Of the seven who died, two had the skull fractured by fragments of shell, with protrusion of brain matter, while the other five succumbed to internal hemorrhage or peritonitis.

"Of the wounded soldiers, 498 were admitted; 34 died of purulent infection, tetanus, internal hemorrhage and severe wounds of the skull and brain, the latter causing the greater part of this mortality. There now remain only 47 cases which will require ambulance transport to the ship.

"The parts involved were mostly the extremities, inferior and superior, much more rarely the chest, head and abdomen. Very many cases were of great gravity, but thanks to the treatment pursued, the skill of the surgeons and the sanitary care of the attendants, all dangerous symptoms subsided in a few days and the cure followed a normal course, the wounds remaining completely aseptic. Here also the striking fact must be stated that not a single amputation was required or performed, a result speaking

high praise for the conservative surgery always advocated by Spanish surgeons, as well as for the treatment followed.

"As a general rule, the bullet passed through the body or limb, making two clean holes, those of entrance and of exit. Some wounds had no hole of exit, but in most of them the bullet lodged near the skin and was easily extracted.¹

"In the case of an officer, the bullet ranged through the face: the hole of entrance was very small and otherwise normal, but that of exit was much larger, with irregular, ragged edges, burnt and discolored by grains of powder; there was much destruction of tissue and healing was very slow. I believe this case was produced by an explosive bullet, such as the insurgents had frequently used before, and that an insurgent was the author of this outrage against the laws of war. Never did the thought enter my mind that it could be imputed to our loyal enemy, the Americans.

"The average time required for the healing of the great majority of our wounded was from 20 to 25 days, even of those most gravely hurt: penetrating wounds of abdomen and chest recovered in a proportion of 70 per cent. with amazing rapidity, without leaving any complications.

These notes, incomplete as they are, corroborate the observations made among our own wounded of the effects of the Spanish Mauser bullet, and justify us in formulating the following conclusions:

1. The rapid-firing, long-range modern rifle, with small steel-jacketed bullet, does not produce a larger percentage of casualties than the weapons used in our Civil War or the Franco-Prussian War.

2. The proportion of killed to the wounded is less than before.

3. Wounds heal with astonishing rapidity, even a majority of those penetrating the abdomen and chest, so fewer deaths occur in field hospitals.

4. Few, if any, primary operations are now performed, and amputations (except as a result of artillery fire) are hardly ever required.

In view of the unsanitary state of the Spanish hospital, and the, perhaps excessive, conservative attitude of the surgeons, the results obtained are certainly very remarkable, and show what, despite adverse conditions, we may expect from an aseptic bullet, rest and antiseptic treatment. These results are, on the whole, better than those obtained on our own side, and the reason must be the necessary and often rough transport to which our wounded were subjected, first from the front to the field hospital, then from the hospital to the sea-shore, from the beach to the hospital ship, and so on, until they reached their final home destination.

SOCIETY PROCEEDINGS.

Association of American Medical Colleges.

SECRETARY'S OFFICE, 104 E. 40TH ST., CHICAGO,
November 26, 1898.

The Association has published its proceedings and already distributed them, six copies to each college holding membership, one copy to every other medical college in the United States and Canada, two copies to every State board of health, and a bound copy to every medical library or large general

¹ On our side, the proportion of bullets remaining lodged in the body was one-fifth or one-sixth, an unexpected and surprising fact.—V. H.

library in the world. Additional copies will be mailed to proper officers and persons on request.

The Judicial Council has recommended to membership the University of North Carolina, and the Medical Department of Kentucky University.

The Secretary has written a large number of medical men requesting co-operation in bringing the action of the AMERICAN MEDICAL ASSOCIATION, in relation to the four years' course, to the notice of local societies with which they are connected. Many encouraging replies have been received.

A large number of three-year schools have signified their intention to make their course conform to the requirements of the ASSOCIATION at their next commencement. Some schools, however, persist in maintaining a shorter course in spite of the action of the AMERICAN MEDICAL ASSOCIATION and the rulings of various State Boards of Medical Examiners.

The Secretary has prepared a very complete bibliography of the Association, which will be published in January.

The following rulings of the Judicial Council are of such importance that they are published herewith:

JEFFERSON MEDICAL COLLEGE—DEAN'S OFFICE,
PHILADELPHIA, PA., NOV. 10, 1898.

DUDLEY S. REYNOLDS, M.D., Chairman Judicial Council Association of American Medical Colleges.

Dear Sir:—I beg to present to the Council a case for their judgment. In our annual circular the attached paragraph appears.

TO ADVANCED STANDING.

College graduates in Arts or Science, who during their college course have devoted the stated number of hours to the study of the following branches or their equivalents—General Biology, 90 hours; Mammalian Anatomy, 144 hours; Chemistry, 216 hours; Physics, 72 hours; Histology, 72 hours; Human Anatomy, 144 hours; Physiology, 48 hours; Zoology, 96 hours; Embryology, 72 hours—are admitted to the second year without an entrance examination. During this first year they must take Materia Medica and Pharmacy (including the laboratory work), and at the end of the year be examined in them. At the end of the second year they must also have completed the dissection of the entire human body and be examined in the entire subjects of Anatomy and Physiology. They have the option of taking first-year Anatomy and Physiology at the end of their first year in this Institution, and their second-year Anatomy and Physiology at the end of their second year. There will be no charge for dissections in their second year.

A student has applied to us for advanced standing to our fourth year graduating class, with the following history: He was for two years in the medical preparatory department of the Ohio State University, and did work in excess of that required in the above paragraph. This work was considered by the Ohio Medical University fully equivalent to their first year and he was advanced to the sophomore year. He remained in the Ohio Medical University through the sophomore and junior years, passing all his examinations, and now seeks to become a member of our graduating class.

The only point against him is that his medical preparatory course did not lead to any degree, either B.S. or M.D. At the Denver meeting the following amendment was adopted: "A college not giving the whole four courses of the medical curriculum and not graduating students, but otherwise eligible, may be admitted to membership." This recognizes the value of work done in a systematic college course apart from the degree. We have been asked to recognize the systematic work done by students in the Ohio State University and the West Virginia State University while taking the medical preparatory course. We find that certain colleges, members of the Association, who have informed themselves as to the nature of this medical preparatory work, have advanced the "medical preparatory" student one year in his medical course for the two years of the medical preparatory. They say that the students are well instructed, and assert their belief in the propriety of their action in spite of the fact that the "medical preparatory" course does not lead to the degree A.B., B.S. or M.D. I ask your ruling on the question. Is it permissible to recognize the two years of medical preparatory work in certain universities as equivalent in time to the first year of the medical curriculum? An early answer will greatly oblige.

Yours very respectfully,

[Signed]

J. W. HOLLAND, Dean.

LOUISVILLE, KY., NOV. 16, 1898.

Dear Doctor:—Please read carefully the enclosed copy of Professor Holland's letter, and the accompanying opinion. If the latter meets your approval, please to sign it and return it to me as soon as possible. If not, please prepare an opinion in

accordance with your judgment, on a separate sheet of paper, and forward it to me as soon as possible.

Very truly yours,

[Signed] DUDLEY S. REYNOLDS, Chairman.
(Exact copy of original sent to each member of the Council.)

ANSWER TO THE LETTER OF PROF. JAMES W. HOLLAND, M.D.,
DEAN OF THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA, PA., OF NOV. 10, 1898.

It is the opinion of the Council that, the Constitution of the Association of American Medical Colleges does not contemplate all the circumstances which may arise in relation to claims for advanced standing, based on previous collegiate training received in regular and systematic order.

Section 4 of Article III, of the Constitution authorizes the Jefferson Medical College to recognize the credentials issued by the Ohio Medical University. The student referred to by Professor Holland seems to have complied sufficiently with the requirements of the Constitution to entitle him to the advanced standing accorded him, provided it can be shown he possessed the preliminary education exacted in Sections 1 and 2 of Article III of the Constitution.

The Council does not presume to say what recognition should be given to the work done by students in the Ohio State University, nor the West Virginia State University, in their preparatory medical courses. Deans must be allowed some discretion in individual cases not specifically provided for in our Constitution.

It is the opinion of the Council, that it is permissible to recognize the two years of medical preparatory work in certain universities as equivalent in time to the first year of the medical curriculum; provided, however, that the applicant exhibits the required preliminary education and passes the standard intermediate examination for admission to the second-year course.

[Signed]

DUDLEY S. REYNOLDS,
STARLING LOVING,
RUDOLPH WINSLOW,
ALBERT R. BAKER,
JAMES H. ETHERIDGE,
JOHN B. ROBERTS,
VICTOR C. VAUGHAN (failed to report).

HIRAM CHRISTOPHER, M.D., Dean, St. Joseph, Mo.:

Dear Doctor:—Your letter of October 29, addressed to Prof. Bayard Holmes of Chicago, has been referred to me for definite answer.

The Association of American Medical Colleges, as you know, was permanently organized at Washington in 1891, in accordance with resolutions adopted by a convention of medical teachers at Nashville, in May, 1890. At the time of the first organization, the Association pledged itself to observe certain requirements, including three courses of graded instruction of not less than six months each, in three separate years, of all candidates for the degree of Doctor of Medicine. In 1894 the Association adopted, to take effect in 1899, and thereafter, four courses of not less than six months each, in four separate years. This action has been so widely published that it could not have escaped the attention of any person in the regular profession of medicine.

In annual session, at Detroit in 1892, the AMERICAN MEDICAL ASSOCIATION resolved unanimously to demand of all colleges in the United States, the adoption and observance of a standard of requirement which should in no case fall below the minimum standards of the Association of American Medical Colleges. In June, 1898, at Denver, after mature consideration, the AMERICAN MEDICAL ASSOCIATION adopted an ordinance making good its demand of 1892 by amending Article IX of the By-Laws, by defining in definite language certain conditions, which shall hereafter exclude from representation in that body.

From your language to Professor Holmes, it is clear you are familiar with that action. There is no probability of any person familiar with the Constitution, the By-Laws and the Ordinances of the AMERICAN MEDICAL ASSOCIATION, being persuaded that the action at Denver was in any sense irregular or in conflict with the Constitution. In the second Article of the Constitution of the AMERICAN MEDICAL ASSOCIATION, under the heading of "Permanent Members," it is specified that, compliance with the By Laws of the Association shall be exacted. At page 15, Article IX of the By-Laws contains a statement of conditions excluding representation. The action at Denver merely extends these conditions to include conduct, of which no one at that time, nor have they yet at this time been guilty.

If, with the warning of that action before you, you feel able to defy the action of the AMERICAN MEDICAL ASSOCIATION, I am

sure you will not find fault with the College Association, nor with the AMERICAN MEDICAL ASSOCIATION, both of which are limited in the application of their rules and regulations to their own membership.

I should not like to see your institution assume this defiant attitude, and I trust you will recede before it is too late. Trusting you may see the advantages to accrue to your school in adopting the minimum standard of requirements of both the College Association and the AMERICAN MEDICAL ASSOCIATION, and that you will be spared the humiliation of being denied recognition by the only organized body of the profession authorized to speak with authority in the United States. I am, very respectfully, your obedient servant,

[Signed] DUDLEY S. REYNOLDS, Chairman.

LOUISVILLE, KY., Nov. 10, 1898.

PROF. JOHN ROGERS, JR., New York, N. Y.

Dear Sir:—Your communication of October 29, addressed to Prof. Bayard Holmes of Chicago, has been referred to me for definite reply.

The Association of American Medical Colleges adopted, in 1894, an amendment to Article III of the Constitution, providing that all candidates for the degree of Doctor of Medicine in 1899 and thereafter, shall have attended four courses of instruction, of not less than six months each, in four separate years. This has been widely published in the medical press, and it has been the subject of judicial determination on several occasions: the Council holding that the language, "in 1899 and thereafter," must be construed to mean from Jan. 1, 1899. With this interpretation repeatedly published, and unanimously confirmed by the vote of the College Association in annual assembly, the AMERICAN MEDICAL ASSOCIATION last June, at Denver, unanimously resolved to support it and deny recognition to any person concerned in preparing students for the degree, as well as those receiving such degree, after Jan. 1, 1899, on conditions below the requirements of our Association.

On examining your announcement for 1898-99, I find at page 18, your college proposes to graduate the class of 1899 on three courses. I very much regret that you have lowered the standard of requirements, and that your institution proposes to await the operation of the statutory requirements of the State of New York. I am sure that your institution would gain greatly by adopting our minimum standard of requirements, and I trust that it is not too late for you to recede from the unfortunate position which you have taken, as you say, "for the benefit of a few men who registered with the old University of the City of New York." We could not admit to membership an institution that openly proposes to violate our minimum standard of requirement. Trusting you may be able to correct this, and that I may yet have the pleasure of recommending your institution for membership in the Association, I am, very respectfully yours,

[Signed] DUDLEY S. REYNOLDS, Chairman.

Chicago Society of Internal Medicine.

Meeting of Nov. 22, 1898.

Dr. JOHN A. ROBISON, president of the society occupied the chair.

Dr. HENRY F. LEWIS read a paper on

MUSICAL HEART MURMURS.

He said in part: Musical murmurs heard over some parts of the heart's area, in various abnormal cardiac conditions, are not uncommon phenomena. They are often due to aberrant tendinous cords stretched across the cavity of the ventricle in such manner that they are tightened by the movements of the ventricular walls and caused to vibrate by the of the current of blood rushing against them. In order that such a cord shall act like a harp string and give forth a musical vibration, it is necessary that it lie directly in the course of the stream of blood, and that there be a vigorous action of the ventricle. The musical murmur in these instances is commonly accompanied by a vibratory thrill. In a recent article in the *Philadelphia Medical Journal* the author considers somewhat at length the influence of aberrant tendinous cords upon the production of these musical murmurs. While cases are not uncommon where such cords are found in other cavities of the heart, he believes only one has been recorded where a musical murmur was produced by a cord stretched across any chamber other than the left ventricle. It is necessary also that the cord be across the aorta or upper third of the ventricle: otherwise no musical sound is produced. Eichhorst states that a musical bruit may be caused by a congenital aberrant cord running from the ventricle to the aortic wall.

Disease of the aortic valve or its neighborhood is a frequent

cause of musical murmurs. Many times the sound is loud enough to be audible at a distance from the chest, even enough to disturb the patient himself. Very loud murmurs usually mean aortic disease. McAlldowie reports a case where the sound was easily heard several feet away from the patient. The autopsy revealed a lacerated flap from the degenerated wall of one of the sinuses of Valsalva, which in life probably projected into the blood stream and gave rise to the systolic "cooing" sound observed clinically. In the case of tendinous cords across the upper part of the ventricle there may be in addition to the systolic bruit or without it, a diastolic musical murmur caused by the regurgitant stream coming back into the ventricle. In relative insufficiency of the aorta there may be dilatation of the ascending portion of the vessel which can cause a musical note heard with diastole.

Huchard maintains that aortic regurgitation due to arteriosclerosis is more commonly accompanied by musical, rough or whistling murmurs than is that lesion due to other causes. Arteriosclerosis is the most frequent cause of aortic stenosis and the murmur with that lesion is often whistling or otherwise of a musical character. While musical sounds are oftenest heard in the aortic region and due to lesion of the corresponding valve, yet sometimes mitral disease may be the causative factor. In mitral stenosis such a murmur may exist with diastole or modifying the presystolic bruit characteristic of that disease. Cases are not unknown where a distinct or even very loud musical sound existed for some time and then disappeared. Such might be caused by vegetations on the aortic valve, which were finally swept away by the blood. Musical murmurs heard in the cardiac region may owe their origin to extracardiac causes. Catarrh of the bronchioles of the adjacent parts of the lung, especially the lingual appendix, may give rise to a musical sound from the beating of the heart next to it. A metallic tinkle may come from the cardiac movements setting up a vibration of the walls of the chest.

Dr. LEWIS reported a case of heart disease characterized by a musical murmur heard about the apex and at the end of diastole. He had made the diagnosis of mitral stenosis.

Mrs. G., aged 45 years, married, never pregnant, native of Ireland, had an attack of acute articular rheumatism fifteen years ago. These attacks recurred from time to time for two years, and then disappeared until two years ago. At this time she had an attack of cardiac failure somewhat similar to the recent one for which he treated her. There was great bodily weakness, feeble pulse, marked dyspnea, orthopnea and obstinate vomiting. She went to a hospital and lay in a state of coma for three weeks. Then consciousness returned and anasarca supervened to a marked degree. At the end of six weeks she left the hospital much improved. Since then she has suffered great dyspnea on exertion, but has managed to do her housework until the present illness came on. Several weeks before his first visit she was seized with constant dyspnea, inability to recline, anorexia and obstinate vomiting, rejecting everything from the stomach for five days before he saw her. His first notes are dated March 21, 1898. He found her half-reclining in bed, gasping, with a shallow respiration at a rate of over forty to the minute. The pulse was so weak and irregular that it could not be counted at the wrist. There was much cyanosis and jaundice with considerable emaciation. There was very little edema at that time, but it increased later. The hands and feet were cold and clammy; she sweat profusely from the exertion of whispering; complained of great pain in a small area in the lumbar back. In short, he found her moribund and advised sending for a priest. The heart beat at the apex was very irregular in time and intensity, counting about 150 per minute. The rapidity of pulse, as well as the rapid and noisy breathing, obscured the auscultation, but he was able to make out a not very loud systolic murmur at the apex. Her condition forbade an extended examination and he made a provisional diagnosis of mitral insufficiency with muscular degeneration and passive congestion of the abdominal viscera. The scanty urine was of high color, specific gravity 1028, showed a little bile pigment and a trace of albumin. In the sediment were hyaline and granular casts stained yellow, a few leucocytes and renal and cystic epithelial cells. He prescribed digitalin (gr. $\frac{1}{100}$) every four hours and a diet of liquid peptonoids. Two days later there was little change, except that the pulse was a trifle stronger and the respirations less difficult and rapid. She had been able to retain half an ounce of the peptonoids every two hours, but nothing else, not even water. He replaced digitalin by strophanthus and aromatic spirits of ammonia. Three days more found her pulse reduced to 70 without intermission, but not regular in force. All the symptoms steadily ameliorated. She was able gradually to add peptonized milk, eggs and other light food in the course of a few weeks. Moderate edema of the legs came on. He prescribed

strophanthus, diuretin and a little digitalis from time to time. The urine became less scanty and concentrated; albumin disappeared, and casts diminished in number. Early in June examination showed albumin and sugar absent; urea 50 grams per diem; uric acid increased; phosphates 1.5 per cent. and sediment free from casts. Edema was never great. June 1, auscultation showed a slight soufflé at the apex, heard with systole, and propagated a little toward the axilla. He also heard then, for the first time, a rather low-pitched musical sound with diastole. This sound covered a considerable area about the apex. Cardiac dulness extended one inch to the right of the sternum and half an inch to the left of the nipple line.

The patient's general condition has continued to improve a little, from week to week, until she has become able to go downstairs, out of doors, and even several miles away from home without unpleasant symptoms. Early in June she had several attacks of partial faintness, accompanied by amaurosis lasting several minutes, but these symptoms have since disappeared. Ophthalmoscopic examination shows a dimness and cloudiness of the disc of each eye and a congestion of the vessels. In the right eye there is a considerable tortuosity of the vessels. Examination October 7 showed the musical sound still present, but weaker, and a complete disappearance of the systolic soufflé at the apex. The pulse was rather rapid and not perfectly regular in force; the area of cardiac dulness not perceptibly increased, nor was that of the liver. Pulmonary signs are *nil*. There was a slight accentuation of the second pulmonary sound, and the patient complained of some dimness of vision in the left eye with scintillation of light before it. The left pupil was slightly larger than the right, but both reacted to light. There was little or no edema; the urine passed freely and was negative in character.

As to diagnosis, the essayist is inclined to think that the present condition is one of sclerosis or calcareous condition of the mitral valve, causing the musical murmur heard at the end of diastole in the region of the apex. He thinks the cause of the earlier severe symptoms was a dilatation of the right ventricle and then the left, giving rise to a relative insufficiency of the mitral, as evidenced by the systolic soufflé which, as the ventricular dilatation has subsided, has since disappeared. At the same time, he recognizes the probability of there still being more or less leakage through the deformed mitral valve.

Another case of musical murmur under his observation at the present time, he reports very briefly. The patient, Miss G., 40 years of age, of nervous and gouty antecedents, has suffered from frequent attacks of palpitation for the past year or more, which later became more frequent and distressing. Recently she complained of feeling a lump in her throat, and at times of a sense of suffocation. Examination showed a slight enlargement of the thyroid, tremor, pulse rate varying between 80 and 120; no signs of exophthalmos. A high-pitched musical murmur was heard with diastole over the right carotid as far up as the angle of the jaw, and for a short distance along the course of the right subclavian. The pulmonary sound was slightly accentuated; the second sound at the apex doubled, and there was a systolic soufflé heard at the apex, not propagated. Deiccated thyroids increased the palpitation and the sense of suffocation, but the thyroid gland has not enlarged. The nervousness and palpitation were modified somewhat by bromide and digitalin; but the condition has been little changed for the last month or two. The blood examination showed 4,500,000 red-blood corpuscles to the millimeter, a normal amount of hemoglobin, and no apparent change in the morphologic aspects of the blood. The musical murmur is diminishing in intensity.

A somewhat similar case of arterial musical murmur in Graves' disease is reported by Forte and Penne. In their case the sound was so intense as to interfere with the patient's sleep. The maximum intensity was over the aortic region and the sound was propagated into the arteries, especially of the right side. In Graves' disease the cause of the musical murmur is not necessarily a cardiac lesion, but may be due to nervous disturbances of the contractility of the heart resulting from the general disease.

Dr. ROBERT H. BABCOCK—The paper has covered the essential points of interest so thoroughly that it leaves very little room for further discussion except by way of amplification of the subject. I am not disposed to take the time of the Society in discussing the causation of the musical murmur, but it unquestionably is due to some condition which favors the vibration of some solid material, a valve, an arterial wall or a calcareous plate, an aberrant cord, or what not. For years I have heard musical murmurs, from time to time, but they have always been systolic, so far as I now recall, with one exception. Something like two years ago I chanced upon a dis-

pensary patient who had a diastolic musical murmur. In this case there was aortic insufficiency. The murmur was loud enough to annoy the patient and could be heard at some distance from the body. It was intermittent. It ultimately disappeared before the patient's death, and at the postmortem examination, which was made by Dr. Sippy and Dr. Evans, no satisfactory condition was found which could explain the production of the musical murmur. An aortic lesion was fully established and was due to arteriosclerosis. Recently, I have seen two cases of aberrant cords, and both cases have come under my observation since Dr. Lewis's paper of last winter. One, a female, I had examined a number of times, and had never detected a musical murmur. On one occasion she became violently excited; the heart's action was exceedingly rapid, 160 or more, and there was developed, while I was auscultating, the most exquisite musical murmur I have ever heard, which seemed to me as nearly like the twanging of a violin string or a bow chord as any thing I could think of. As the heart quieted down the murmur disappeared. These murmurs are of great interest, but are rarely of especial diagnostic import. They may help us to understand the pathologic condition in a measure, and yet I do not think our knowledge of the conditions which call forth musical murmurs is such that we can always predicate with anything like accuracy the exact condition which gives rise to the musical quality of the murmur. The disappearance of the murmur in my case was due to cardiac enfeeblement.

Dr. JAMES B. HERRICK—Occasionally, the louder the murmur and the more distinct the musical quality, the better the prognosis. As I listened to Dr. Lewis's report of the case, I wondered whether in this instance, when the patient was first observed, on account of myocardial weakness the blood currents were so feeble that they did not give rise to a musical murmur. Perhaps the condition of the patient today would throw some light on that point. As the patient's murmur has again disappeared, it may be that, at the same time, the heart muscle has once more become weak. As Dr. Babcock has said, from a diagnostic standpoint these musical murmurs are, perhaps, as Flint terms them, "mere clinical curiosities." And yet from a careful study of clinical cases and from postmortem observations, we may at some time be able to make certain definite statements concerning the lesion that exists from the character of the murmur, and such papers as that of Dr. Lewis are extremely valuable as helping to get together the histories of a great many of these cases. Laennec, as Dr. Lewis has said, laid a good deal of stress upon the musical character of murmurs. I believe, in his original edition, he even represented them by musical characters showing their exact pitch. His more practical English translator (Forbes) quietly cut out a good deal of his discussion as to the musical character of murmurs; and Latham, one of those clear-headed English writers, in the early part of this century, said that the musical or other quality of the murmurs was of little practical value, though when auscultation was first introduced in England and physicians began to listen to the heart, they were not only captivated by the sounds they heard and by the whole study of auscultation, but they made it considerable of an amusement, and tried to see how nearly they could compare the murmurs to various other sounds, and he says that they even went so far as to represent them by musical notes.

Dr. BABCOCK—Was it not Latham who reported a case in which a musical sound was heard like that of the cuckoo cooing, and yet nothing was found postmortem to explain it?

Dr. HERRICK—I do not remember. Speaking of diastolic musical murmurs, the loudest musical murmur I ever heard was diastolic and in a case of typical aortic regurgitation.

Dr. LEWIS (closing the discussion)—In answer to Dr. Herrick, I think he is right in regard to the condition of the musical murmur in my case. It is a fact that the murmur was not heard while the heart muscle was in a very weak condition at the same time that the heart must have been dilated, at which time there was a loud systolic murmur. I spoke of the difficulty of examining in her weak condition and said that the respiratory sounds were much disordered. Before this time, in the hospital they had discovered a cooing sound, as of a bird in the chest. Since the murmur has begun to disappear again, she is improving, and the heart muscle seems to be stronger.

Dr. CHARLES W. PURDY read a paper entitled

THE PRINCIPLES OF THE DIETETIC TREATMENT OF DIABETES MELLITUS (*vide* JOURNAL, December 3, p. 1329).

Dr. N. S. DAVIS—I have not for a long time listened to the reading of a paper that was to me more interesting and instructive than the one just heard. It reflects the thought of the best students of this subject today. I think the pendulum of medical opinion has swung completely away from the belief

that was so prevalent some time ago, that diabetic patients must be excluded entirely. The prevalent opinion now, at least among those who are studying diabetes most carefully, is that a modicum of carbohydrate foods can be allowed to most patients. The exact quantity must be determined for each patient experimentally and by careful tests of the digestive capacity of each patient. As Dr. Purdy has said, the quantity which each patient can tolerate varies during the course of each one's illness; therefore, a constant watch of the digestive powers of each must be kept. There is a time, it seems to me, when we can place patients upon a strict diabetic diet, as it was formerly called; it is when they first come under treatment. All carbohydrates should then be forbidden in order that we may learn whether we can thus prevent the elimination of sugar by the kidneys. If the latter can be made to disappear, then one can carefully administer small and increasing quantities of starchy food to ascertain how much will be assimilated. Under these circumstances a strict diabetic diet, or one from which carbohydrates have been excluded, is useful, but only for a short time. Again, oftentimes when diabetic coma, or nervous symptoms which lead us to suspect its onset, threatens, patients can advantageously be placed upon a strictly diabetic diet. There are, however, a group of cases that, under the same circumstances, suffer from indigestion, which often seems to have been produced by crowding albuminous and fatty foods to the exclusion of carbohydrates: such patients are frequently benefited by permitting a mixed diet for a little time, that is, throwing aside the dietetic barriers that have been erected. Immediate improvement is not uncommon under such circumstances. It has seemed to me, from some experience, that it is not desirable to place patients upon a closely restricted diet suddenly when they first come under treatment. Patients do better if one at first inquires carefully as to what foods they have been using, and if one article of food is eliminated after the other until they are day by day gotten upon a sufficiently restricted diet. In many cases that I have seen indigestion has been common by suddenly restricting diet, and the patients felt worse rather than better. In at least two instances in which coma developed and proved fatal, it seemed to be precipitated by the sudden change of diet. At least, this was the impression made upon me. Two or three cases are not enough, however, to generalize from. It seems desirable to put patients very gradually upon a restricted diet if they are to be placed upon it at all.

I was extremely pleased with Dr. Purdy's opening remarks as to the necessity of forming a compact, and cast iron agreement, between patient and physician, in order to successfully treat cases of diabetes. Patients in advanced life can be most successfully treated, provided only they are constantly under a physician's guidance. Examinations of the urine must be made frequently. One must have a complete knowledge of the character and quantity of foods patients are taking, and he must look to even the minutest details of hygienic treatment, both dietetic and otherwise, in order to insure success in the treatment of these cases. Frequent examinations of the urine are absolutely essential. The first symptom of relapse or recurrence in patients who have been helped must be looked for in order to properly adjust their diet to their varying needs. This watch must be maintained continuously over years of time, in some cases. In regard to individual articles of diet, the diet lists which I have been in the habit of prescribing are not very different from those Dr. Purdy recommends. I have not added the use of fats as frequently as I wish I had until the last year and a half. I believe that I get better results by giving fats more generously than I used to do. There is, however, chiefly the danger when patients are put upon a fat and albuminous diet, of creating digestive disorders. It is very difficult in some cases to get enough of fats taken to accomplish good. It is best to permit the use of so much of carbohydrates as experience shows are assimilable and to substitute fats for them when none or little can be taken.

Dr. JOHN H. HOLLISTER—For many, many years I have had occasion to watch the progress of cases of diabetes, and I have formulated some conclusions in my own mind which occur to me at the present time. In the first place diabetes is perhaps one of the most interesting diseases for clinical study on the part of the attending physician, and one of the most fruitful that can claim our consideration. The subject-matter of the paper is proof. It involves the whole subject of nutrition; it involves the molecular changes which are incident to tissue building and the removal of excrementitious matter: it involves processes in which the structure and function of the kidney is inseparably related. This leads me to the thought that we have such a great variety of conditions that the cases must be treated individually. As has been remarked, we need to study each individual case more critically than in almost any

other disease, and if this can not be done we can not lay down any specific line of treatment that shall be applicable in any large number of cases. My experience has led me to the conclusion that there are few persons, except under hospital control, who are satisfactory patients. It has occurred to me, and to all of you doubtless, that most of those who suffer from glycosuria are in conditions of health where they like to care for themselves, and very frequently are scarcely amenable to control. The frequent indiscretions of my patients have led to discouragement on my part with reference to the treatment of this disease. As Dr. Davis has said, nothing but a cast iron rule can avail, and only those under absolute hospital control seem to give us a fair chance to study the results of treatment. For many years I have been in the habit of gradually changing the diet list, never abruptly, but gradually withdrawing objectionable articles of food till I have brought them down to the point where it seemed to me for a period of time a struggle between their appetite and their wish to obey me was the point at issue, and beyond that point I hardly think it is wise generally to control them, so much so that as the amount of sugar comes to a low point I have sometimes gradually introduced the carbohydrates to see if there was any increase beyond that point, if not, to permit their limited use, and if there was an increase, to withdraw, and I have quite frequently found that a gradual improvement went on, even though I gradually introduced hydrocarbons in connection with their food. And so in the cases that have come under my observation I have endeavored to study individually the manner, results of introduction and withdrawal. One point in the last suggestion of Dr. Purdy struck me very forcibly. It results from three cases I have notes of in which there were intercurrent diseases and the further free use of food was forbidden, and in which sugar disappeared for the time, with the withdrawal of food. The withdrawal of the excess of food gave immediate rest, and the result was very favorable. I have sometimes felt that some of these cases were permanently relieved; but a greater misfortune has been to find, through errors of diet, repeated returns of the disease, and when this is the case I find any form of treatment less available. I have hope for those who have judgment and will-power and will control themselves for any period of time after they seem to have perfectly recovered, but I have none for those who are indiscreet.

With regard to the use of alcohol in diabetes, I have not used it as freely as has been suggested, and I do not know its results as well. I have found that the fatty foods introduced have been favorably received by most of my patients, to the extent that I have inclined freely to administer in connection with the foods that have been mentioned, cod liver oil as a drug or in emulsion, and I have come to regard it in connection with the other articles of food as a favorable part of the diet.

Dr. JOHN FISHER—The question of diabetes is one in which more physicians ought to be interested, and we ought not to let this debate go by without further remarks. The first thing necessary in treating a case of diabetes and in teaching the subject, is a better classification than we have ever had. Dr. Purdy has read a paper tonight upon glycosuria, with a very slight attempt at classification of the cases. There is no physician perhaps in this Society who, in treating several cases of this disease, has not been struck by the great variation in the kind of diabetes that he was treating. For instance, when we get a case of so called glycosuria in a child, we feel that it is going to prove fatal in a short time. When we get a case of glycosuria in a young man who has a ravenous appetite, who consumes gallons of water daily and passes large quantities of urine loaded with sugar, we know that patient will last but for a short time unless we have some method of checking this dread disease. We encounter the disease in older men, say between 35 and 45 years old, who are lean; the kind that Dr. Purdy has referred to, men who have only a moderate appetite, or one which is below normal, while others have quite a ravenous appetite. Dr. Purdy holds that in such cases the proper thing is to make those patients gain flesh. The question comes up, What is the best treatment in order to make those patients gain flesh, and at the same time reduce the amount of sugar in the urine? There are several classes of cases of diabetes: the little child who rapidly declines; the young man or young woman who goes rapidly down; the lean man who has reached middle life or has passed it, and then there comes the older person who has reached 50 or 55 years of age, who, as Dr. Purdy says, is more amenable to treatment than any of the others. It is peculiar that when a person gets old they can stand disease better than a child, and it is a wonder to me whether there is not a different etiology for the glycosuria in a child than that in an old person. There is another class of patients who have diabetes, not uncommon, and they are fleshy people. I have, for instance, under my care at the present

time three such men, two of them six feet in height, one weighing 300 pounds, one 280, and a third, five feet eight inches in height, who weighed a few years ago 268 pounds. Dr. Purdy has told us that in cases of glycosuria the thing to do is to get the patients to gain flesh, and I want to ask the Doctor if he would want these men to put on any more flesh? I do not ask him this question in a spirit of fun. One of these patients in the last six weeks, under treatment, has decreased in weight from 268 to 252 pounds, and I was under the impression that this was a good sign and encouraged loss of flesh. This loss of flesh may be due to his restricted diet, but he had an extraordinary good appetite, drank large quantities of water previous to treatment and was getting up every two hours at night for the purpose of urinating, and sometimes every hour. Under a restricted diet he has been able to go all night without passing any urine. The quantity of glycosuria was eight grains to the ounce when treatment was commenced; at the end of three weeks, he was without any sugar in his urine, and this continued for three weeks, when the condition again returned, so that last week the quantity of glycosuria was four grains to the ounce. It has been a question in my mind whether this fleshy man would not be better off if he lost a good deal of flesh. The same may be said of the other cases. I am positive that these men are in a safer condition with diabetes than lean men would be with the disease. I believe most of you would rather treat a fat diabetic than a lean one. It has struck me that there is some difference in the cause of diabetes in different cases, and if there is, we can not treat all patients alike. It has been suggested that the liver may sometimes be the cause of it. In several cases where postmortem examinations have been made, disease of the pancreas has been found, I think in about one-third of the cases. Other organs have been found diseased in some cases. If the etiology is different our treatment ought to be different.

Dr. JAMES B. HERRICK—Dr. Hollister really made the few remarks that I intended to make. He touched upon a very important point, and that was the fact that our patients who were dieting acquired a certain tolerance for carbohydrates. And I would call attention to the way in which Van Noorden puts it in the classic article which he has written on this subject, and which Dr. Purdy has so highly commended. He states that improvement in the mild or moderately severe cases is not brought about by exercise of the cells, but by rest of the cells. By the withdrawal of the carbohydrates for a time the cells that have been surfeited with too much carbohydrates, too much sugar, are given a period of rest, and they are enabled to acquire tone, so that they then become tolerant of foods that they before rejected. The comparison is not inapt between the condition of these cells and the muscles of a heart that has given out. Where the heart muscle is extremely weak, the heart perhaps dilated, we know it is only by keeping the patient quiet in bed, in the recumbent position, that the heart muscle is enabled to recover its tone. Then when the muscle tone has been recovered the heart will permit movements of the body or physical exertion, as for example ascending the stairs, which before it would not tolerate. In the same way the cells, according to Noorden's theory, reacquire their tone and utilize carbohydrates they before rejected. Some of the older practitioners have, in the course of their experience, gotten on to some of the same facts that Noorden has so tersely, neatly and systematically stated. As Dr. Hollister tells us, he learned this fact of tolerance and the value of fast from his experience. And ten years ago one of our honored physicians taught me that cod liver oil was a good remedy to give to patients with diabetes. I remember at that time having put a patient upon a strict diabetic diet; the sugar lessened, but the woman also grew weak and was losing flesh. I said to the late Dr. C. W. Earle, "What can I do for this woman?" and he replied "Give her cod liver oil and cream, of course." I did, and she improved very much and is living today. Dr. Earle had somewhere learned the value of fats, and he gave to many of his patients who were affected with this disease large amounts of cod liver oil and fat. I do not want to inflict the diabetic bread question upon the society, but I should like to ask Dr. Purdy whether, in his experience, any of the so-called diabetic breads are really reliable and are to be advocated. Several authors, e. g., Williamson, Naugyn, Noorden, and others speak of them as frauds. I should therefore like to know what has been Dr. Purdy's experience with these breads.

Dr. EDWARD F. WELLS—The author of the paper should be congratulated upon having presented a contribution of exceptional value upon a subject which is of great practical importance and extremely interesting. The paper bristles with points of great practical importance. One of the first of these is the statement that the disease is in many cases, especially in elderly people, a controllable one. Another is that skill and

time are required in the management of cases of diabetes. Now, there can be no doubt that a patient with diabetes will fare much better in the hands of one physician of moderate ability than he will at the hands of many physicians of the greatest reputation, that is, going in turn from one to the other. If a diabetic patient can be kept in the hands of one physician week after week, month after month, and year after year for many years, his condition may be greatly improved and his life indefinitely prolonged. In order to do this, however, he must have confidence in his physician. There is only one way to obtain and retain the confidence of a diabetic patient, and that is to treat him fairly and truthfully; take him into your confidence and perhaps a partial partnership in the management of his case, and it is well to state to him, as early as possible, exactly and in some detail, what he can and what he can not expect. Many of these cases can be improved only to a certain extent; the sugar diminishes to a mere trace, but can not be entirely done away with. The thirst declines, and the amount of urine passed approximates the normal; yet, with every care and management, these patients do not get beyond this point; they are made worse if they are not very careful; with them the limit of improvement has been reached. It is extremely discouraging to such a patient, if he has been led to expect that he can be radically, or completely cured, to find that he can be improved to this extent, but no further. It is, therefore, the height of folly to promise too much, but for the legitimate encouragement of the patient he should be informed, approximately, to what extent he can probably be benefited. The best thing for the patient, then, to repeat, is to tell him as early as possible just how far he can be improved and, if you know, why he can not go beyond a certain point. I am sure that the proper appreciation of those points will be of the greatest benefit to diabetic patients. I have had under my care for several months a patient who was troubled with great frequency of micturition, without much urine being passed, only about fifty ounces during the day, and the amount of sugar being reduced to a mere trace. For the relief of the frequent voidance of urine, sulphonal was given in doses of two and a half grains, three times a day. The sulphonal was continued for a long time without my knowledge, during which the patient improved very much. The urine was examined frequently, and starchy foods were gradually added, so that the amount of these which the patient was able to take during this period was much greater than before. Upon discontinuing the sulphonal, the sugar soon considerably increased in amount, so that a return to a more restricted diet was necessary. The question arose in my mind whether the sulphonal had anything to do with the temporary improvement in this case. Another question I would like to ask the essayist is whether he has noticed any relation between tapeworm and diabetes. Two of my patients, one seen several years ago, and one now under observation, happen to be troubled with both tapeworm and diabetes.

Dr. PURDY (closing the discussion)—With regard to the use of carbohydrate foods in diabetes, I think a great deal of damage is done by using them too freely without carefully watching the results upon the urine. It is quite a fad in cases where the stomach rebels against proteid foods, to return temporarily to the carbohydrates, but I think we can do better by simply reducing the quantity of food. In other words, I believe in strictly dieting these cases. If diets are of any use at all, let us follow them carefully, scientifically and accurately. I quite agree with Dr. Davis that patients should have all the carbohydrate foods they can assimilate and use, but no more, unless they can tolerate a great deal. If they can take 300 grams of carbohydrates and assimilate 200 grams, I would give them a moderate amount of carbohydrate food. But we should follow carefully every gram given by observing the urine for twenty-four hours, noticing what amount of carbohydrates has gone astray, and what amount has been used. I make these remarks because one of the most recent authors upon this subject, Williamson, makes the statement that the more severe the case of diabetes, the more liberal he is with diet. I would recommend exactly the reverse of it, and would say that the more severe the case, the more strictly would I diet it. With reference to the remarks of the Doctor who spoke of building up the body weight of the patient, 300 or 280 pounds is an excessive weight for a man even six feet high. Speaking generally, there is no question but what the higher we maintain the weight of the patient, the milder the disease will run. Any physician who has had much experience with these cases must have seen cases where the patients maintained good body weight and practically assimilated large quantities of carbohydrates; but the moment such patients lose their weight, especially if they become spare, it is an unequal fight to the end that they will lose it. Take a man and reduce him to 130

pounds and his case will go from bad to worse. If he can maintain his weight up to 170 or 180 pounds, he will go along favorably under proper regulation of diet. Other conditions being equal, and his case will progress altogether differently.

With regard to breads, I look upon them as humbugs, nearly every one of them. I think they have killed more diabetics than any other one thing. I have in my book gone over this question and pointed out the quantities of starch in the so called group of diabetic breads manufactured in this country. The bread made in this city by Mr. Jerome, and to which Dr. Davis called attention at a meeting of the Chicago Medical Society about a year ago, is absolutely free from starch. But like all diabetic breads, so-called, it contains a small amount of sugar. I have used it, and consider it the best substitute for the bread I have used. It is necessary to warn the patient in using this bread that he can not use it like ordinary bread. He must not use over half the amount of ordinary bread; if he does, it will act just like so much more proteid food.

I wish to correct the impression conveyed by Dr. Wells in his remarks that diabetes is curable. I did not intend to convey the impression that it is ever curable. What I did say in my paper was, that diabetics beyond middle age, fairly well preserved, if they die of the disease it is either their fault or that of their physician; that this disease can be kept under control by a proper system of diet. But I believe once a patient is diabetic, he is always diabetic in the sense that he can not return to the use of carbohydrate foods *ad libitum*. I have seen cases, however, where glycosuria was brought about temporarily by the excessive ingestion of carbohydrates, which, when cut off, would cause the glycosuria to disappear. Replying to the question of Dr. Wells, I have had no experience with diabetics in connection with tapeworm. I have had no experience with sulphonal or cod-liver oil in the treatment of diabetes. In fact, I have little faith in the specific action of drugs in this disease.

Chicago Medical Society.

Joint Meeting of the Chicago Medical Examiners' Association and this Society, held Nov. 16, 1898.

Dr. JAMES H. STOWELL occupied the chair.

Dr. NICHOLAS SENN addressed the Society on the
SURGICAL DISEASES OF THE LATE SPANISH-AMERICAN WAR, WITH
A VIEW OF ESTIMATING THE WAR RISK OF LIFE
INSURANCE COMPANIES.

He said that the late war had been characterized by decisiveness and by intense patriotism on the part of the troops; while he had reason to believe that the opposite mental conditions prevailed in the Spanish camps. The American troops had to deal with an impoverished, half-starved, discouraged enemy, which he thinks accounted for the easy victories and short duration of the war. He attributes the repeated victories on land and sea more to the soldiers than to any special military genius displayed by any of the commanders. Speaking from a surgical standpoint, he made the statement that the loss of life on the battlefield, or as the immediate or remote effects of wounds did not exceed 400. The loss in battle in Cuba was 267. A number of the most seriously wounded have died since. In Porto Rico, where there were four skirmishes, the number killed did not exceed 20, and the number of wounded was about 40. The Spaniards were armed with Mauser rifles exclusively. He had abundant opportunity to compare the injuries inflicted with the Krag-Jorgensen rifle and the Mauser rifle, and the wounds differed very little. If any, the Mauser rifle was a more humane one, owing to the smaller caliber of the missile. The stopping power of these guns had been over-estimated, as every hunter of large experience knows. In examining from 1200 to 1300 of the wounded, he was astonished at the limited zone of confusion of the soft parts, which explains very satisfactorily the readiness with which these wounds healed, provided no infection occurred. There is a zone of comminution from both weapons at a range of about 500 yards. He found two cases, among the Spanish prisoners, shot with Krag-Jorgensen rifle, gunshot wounds of the femur at the junction of the lower with the middle third; in both instances infection had occurred. The patient suffered from progressive sepsis; amputation was indicated, and promptly performed in a most primitive way, outside of the Spanish column, in the hot, broiling sun, there being no way of effecting disinfection of the dressings, instruments, etc., except with a kettle of questionable cleanliness. Heat was resorted to exclusively in effecting sterilization. At a certain range he is satisfied that both of the bullets from these rifles will inflict injuries to the long bones and produce more or less comminution. In one instance a young soldier was shot through the

tibia two inches above the ankle-joint with a Krag-Jorgensen rifle, and the hole through the bone resembled very much one made with an ordinary drill. The shot was fired at a range of 1000 yards, but there was no comminution whatever. He referred to the value of the first-aid dressing. In Cuba the military surgeons were hampered in their work by lack of dressing material, also imperfect ambulance facilities. Then, too, it must be remembered that in Cuba hundreds were wounded and nearly 300 killed in three days; consequently the medical department was taxed to its utmost capacity in taking care of the wounded with the limited facilities at their command. In this war, with an insufficient number of medical officers at the front, as shown at the time, men occasionally had to wait for hours, and in a number of instances more than a day, before they were picked up and the first dressing applied. It was in those cases that suppuration most frequently occurred. In Porto Rico it was different. General Miles, who had command of the invading army, took every precaution to look to the welfare and the efficiency of the medical service. He felt the need of a medical adviser and often consulted him. The reverse was the case in Cuba. In Porto Rico affairs were conducted near the fighting line. The ambulance corps was in readiness, and ambulances were to be had in abundance. The moment a man was shot he was carried to the rear and a first-aid dressing, always on hand, was properly applied, and of about forty cases of all the wounded brought back from Porto Rico on the hospital ship *Relief* there were only two cases of suppuration, a remarkably small percentage, proving conclusively the value of a timely, efficient first-aid dressing in preventing wound infection.

He made interesting observations in studying the wounded in Cuba with reference to the sources of infection. In examining over 1000 cases, he became fully satisfied that the small caliber bullet seldom, if ever, carries with it pieces of clothing or any other infectious substance. The bullet itself is practically aseptic, as he had abundant opportunity to observe. In the majority of cases where wound infection occurred, he attributes it to the subsequent too frequent change of dressings and unjustifiable attempts to probe the track of the bullet. He had placed himself on record before going to Cuba, that he considers it unjustifiable, certainly unscientific, to resort on the battlefield or in military hospitals to the probe as an instrument of diagnosis.

He has seen a number of cases of gunshot wounds of the abdomen recover without laparotomy. He believes he was the first one to place himself on record, years ago, that a man shot through the abdomen from before backward on a level with the umbilicus or above, has a fair chance of recovery without operative interference. It is in those cases that the intestinal canal not infrequently escapes injury. In four out of sixteen experiments made for the special purpose, careful subsequent examination of the contents of the abdomen showed absence of visceral lesions which would have demanded a laparotomy. These are the cases that recovered during the late war. In almost every instance the bullet wound was on a level or above the umbilicus. The reverse was the case when the bullet traversed the abdominal wall below the umbilical level, and particularly if it passed through the abdomen transversely or obliquely.

There is one part of the surgical treatment of the wounded which he very much regrets was imperfectly performed. Praise should be given where it is deserved, and criticism bestowed where it is called for. He refers to the want of early immobilization of fractured limbs. At the front he could find no plaster-of-Paris, which should always accompany a fighting army. At Siboney he was furnished with plaster-of-Paris, but it would not set. Plaster-of-Paris dressings, therefore, the sheet-anchor of the military surgeon in the treatment of compound fractures, were lacking or imperfect. Surgeons had to do the next best thing—search for splint material, and fortunately in Cuba nature was very kind to the military surgeon in this respect. The supply of wire splints was limited; it would not go one half the distance, but the cocoa palm did the rest. He found in the sheath of the cocoa palm leaf a most excellent material, in that it is somewhat plastic, porous and was utilized to great advantage in the immobilization of gunshot fractures.

In contrast to the experience in the Civil War, he found in the Spanish-American War that penetrating gunshot wounds of the knee-joint, of the hip-joint, and of the larger joints, recovered promptly, never proved fatal in the absence of wound complications. The men recovered, as a rule, with useful joints.

When he came to Montauk, where he was on duty for four weeks, he had an excellent opportunity to study the conditions of the returned soldiers, of which there has been so much said, particularly in the "yellow press." At this camp he did sur-

gery of a peculiar kind, and his experience there perhaps would be of more value to life insurance companies and their medical examiners than what he had said in reference to gunshot wounds. When the army of Cuba returned, it was an army of patients, not of soldiers. They were all anemic, emaciated, and, with few exceptions, brought with them, as an undesirable inheritance, malarial intoxication. In almost every instance physical examination showed enlargement of the spleen. As the result of infective substances in the gastrointestinal canal, he met at Montauk with numerous instances of surgical affections directly traceable to intestinal infection. He found a number of instances of enormous ischio-rectal abscess, anal fistula, hemorrhoids, ulceration of the rectum, varicocele and hernia. He attributes the prevalence of perianal and para-rectal suppurative processes to antecedent attacks of catarrhal proctitis, from which almost every one of the soldiers suffered at one time or another. It was at Montauk where he believes he was of most service to the troops, being placed in charge of the surgical department of an enormous National camp filled with thousands of sick soldiers. He is positive, as far as the Illinois troops are concerned, that not a single private was sent to the front with hernia. Exceptions were made in the case of officers. Speaking of privates, the examination of them was so rigid that he was sure not a single hernia escaped attention, and yet some of the men are coming back with hernias. He was astonished at Montauk at the number of cases of hernia that the soldiers claimed to have contracted during their short service. What is the cause? The fact remains, that the men were never exposed to forced marches; the longest march in Cuba was from Siboney to the front at Santiago, a distance of nine miles. He attributes the prevalence of hernia in the returning soldiers to the debilitating effects of the campaign and of disease; to the relaxing influence of the climate; to the disappearance of fat in the region of the inguinal canal. In the near future many of the mustered-out men will apply for pensions for the defect he has just mentioned. In an examination of ten thousand men at Camp Tanner, he found varicocele with great frequency in men of military age, as from 18 to 45 years. At least 25 per cent. of the applicants for military service were affected with varicocele. In not more than two hundred out of the ten thousand did the enthusiastic and ambitious recruits acknowledge that they experienced any inconvenience from this affection. He therefore believed at that time that varicocele of moderate size, without symptoms, should not disqualify an otherwise well built man for military service. He has every reason now to believe that the position he took then was the correct one, judging from his observations of the men that are returning.

Dr. WILLIAM CUTHBERTSON read a paper on

THE ENTERIC DISEASES OF THE ARMY CAMP IN THEIR RELATION TO LIFE INSURANCE.

He said it was the province of the life insurance examiner not only to pass upon the present condition of the applicant's health; the probability of his dying in a short time from some acute disease, but also as to the probable effect on his life expectancy of any disease the applicant might have had. Anything which may in any way impair the health of an applicant, should be carefully inquired into, and he maintains that camp diarrhea and dysentery are two of the most important of these diseases. The history of all armies operating in all parts of the world shows that camp diarrhea, typhoid fever and dysentery are the most prevalent disorders. They exist to a greater extent, however, in campaigns in very warm or hot countries. The records of our Civil War show that diarrhea and dysentery were more frequent and fatal in the Central region than in the Atlantic and Pacific regions. On the contrary, in civil life, intestinal inflammation is more prevalent in the Northern, Middle and Western States than in the Southern. During the recent Spanish American War, while his regiment—the First Cavalry—was stationed in Illinois, the universal intestinal complaint was constipation; while almost immediately after their arrival at Chickamauga Park, Georgia, diarrhea began. This was so invariably the case that whenever a batch of recruits arrived from home, one would hear a member of the Hospital Corps remark, "There comes more diarrhea." The summer months of June, July and August are those in which the greatest number of cases occur and the mortality is the highest.

The three most important factors in the causation of camp diarrhea, dysentery and typhoid fever are:

1. The effects of excessive or prolonged heat, which tends to weaken or arrest the digestive functions, leaving in the stomach and intestines undigested masses, which act both as irritants and culture grounds for the development of fermentative bacteria. On the other hand, excessive cold chills the

surface of the body and congests the blood-vessels of the digestive mucosa, thus precipitating a camp diarrhea which soon runs on into a dysentery.

2. The totally changed conditions under which an army is compelled to live when campaigning from that which its members were accustomed to while in permanent barracks, or at home in civil life.

3. To the food and cooking. It is a hard task on the stomach to accustom itself to the rations furnished by the War Department during active service, more especially when that service is performed in a hot climate. His experience with the cooks in the volunteer regiments convinces him that a great deal of the camp diarrhea which existed was due to the careless and improper way in which the food was cooked and prepared.

The character of the water ingested is another cause for these diseases. Water containing inorganic salts in solution is very often purgative. According to Parkes, water which contains three to ten grains of putrescent animal matter may be hurtful. Water found in stagnant pools or marshy places has a slight effect on the intestinal mucous membrane, producing diarrhea. Sudden changes from heat to cold, unripe fruit, alcoholic excesses, are all conducive to these maladies. Finally, in the production of these diseases are numerous bacteria which give rise to putrefactive changes in the intestinal contents where digestion is impaired.

Enteric fever has proved to be the scourge of the late Spanish American War. The greatest mortality did not occur where expected, namely, on a foreign soil, from bullet wounds and yellow fever, but right at home in large camps, where every appointment should have been up to date, with every appliance modern sanitary science could devise. These deplorable results can be directly chargeable to the Medical Department of the regular Army. A wet soil, damp weather, the presence of large quantities of fecal and decomposing matter, and large numbers of men congregated together, furnish a beautiful combination of circumstances for the development of this disease. The presence of hucksters in the camp seemed to be responsible for the spread of typhoid fever in no small degree. The eatables which they hawked from regiment to regiment became infected, and in this way was the disease transmitted. At Camp Thomas, Ga., part of the water-supply was taken from the Chickamauga River, the intake pipe being situated only a few yards above the point where one of the large camp drains emptied into the river. The rest of the water-supply of this camp was obtained from springs and wells located on different parts of the grounds, which soon became infected from the leakage through the already infected soil. Finally, the men themselves invited an attack of typhoid fever by their mode of living. They slept on the ground, very often four in a tent, the tent poorly ventilated, and very frequently closed up all day. They would do this in spite of all orders and warnings. They would buy food from hucksters, and drink river water, in defiance of all advice to the contrary. He is of the opinion that not only the water, but the soil, and even the air of these large camps were infected with the typhoid bacillus.

He entered into the causation of these diseases rather extensively, in order to show the extreme liability of the soldier to contract some of them; hence his undesirability as an insurance risk.

The average mortality of selected risks—and all the soldiers in the late war could be classified as selected risks—is 4 or 5 per 1000 per annum. The latest returns show the mortality of the American Army to have been 10 per 1000 for a period of six months, or four to five times greater than it should be. These percentages should settle definitely the question of the desirability of the soldier as an insurance risk, in the negative. Our woods and plains teem with good material for soldiers; we have an unlimited number of first-class medical men and sanitarians. We have a generous people, and he was assured that when the army is reorganized, it will be put in such a condition that during any future campaigns, the life and health of the soldier will be as well protected as if he were under his own vine and fig tree.

Denver and Arapahoe Medical Society.

Nov. 9, 1898.

Dr. WALTER HILLIARD read a paper before the Society on THE SIGNIFICANCE OF CERTAIN LESIONS OF THE FUNDUS OCULI.

He said in part, that a cursory glance at certain anatomic features of the fundus oculi will suffice to explain its peculiar liability to pathologic changes. Incidentally it may be well to note some similar characteristics of the cerebral cortex in consequence of its embryonic and other important relations to the

retina. The cerebral cortex and retina are examples of organs having the so-called "end-artery system." In these structures the arteries, with some unimportant exceptions, neither communicate with those of other parts nor, indeed, with each other. Even the arterioles may be termed "terminal," each one ending in its own capillaries. Another feature of importance is the capillary network of the retina, which is the finest and closest in the body. Their total area is at least 800 times greater than that of the short posterior ciliaries, from which they arise. In consequence of the law that the velocity of a current in a tube is inversely to its lumen, the velocity of their capillary current must be very many times less than that of the short posterior ciliary artery. The choroid presents another peculiar feature—its vessels are arranged in superimposed layers, progressively diminishing in size from without in. In the profound chronic toxemias produced by such causes as syphilis, chronic albuminuria, alcohol and diabetes, the earliest manifestations of the long series of necrobiotic changes are found in the arterioles and capillaries. *A priori* we should have anticipated this. Here the blood-current is slower than elsewhere, and the blood charged with toxic substances is in contact with the delicate structure of these minute vessels much longer than in the larger arteries and veins. In every study of the degenerations resulting from such chronic dyscrasias as just mentioned, one should constantly bear in mind that the necrobioses in the essential structures of the organs occur *after* the vascular lesion, and are largely *due* to them. The ophthalmoscopist heeds not the black luxuriant locks, the beaming countenance, the firm elastic step of youth and manhood's prime, neither does he regard the gray hair, the wrinkled face, the bent form, the unsteady gait of his patient, nor, indeed, the care-worn look so characteristic of the old veteran of life's many storms, but in these chronic toxemias his prognosis is based solely upon what he observes in this beautiful little mirror—the fundus oculi.

In syphilis, chronic albuminuria and diabetes the lesions of the fundus oculi may always be regarded as terminal symptoms: the chancre, the bubo, the cutaneous rash are but memories of a distant past; the renal epithelium, the Malpighian bodies, the glomeruli were long since helplessly disorganized; it is a genuine and not evanescent glycosuria that we have to deal with. The presence of these lesions in the fundus oculi in the albuminuria of pregnancy bodes the imminent danger of a long train of disaster to the woman. Not only should her uterus be relieved of its contents, but the woman should be advised never again to become pregnant. The appearance of these necrobiotic lesions in connection with acute infectious disease is highly significant of a concomitant meningitis, especially basic meningitis.

Dr. Wm. C. BANE reported a case of

VISION OF RIGHT EYE DESTROYED BY THE KICK OF A HORSE ON RIGHT SUPRAORBITAL RIDGE AND RIGHT CHEEK.

On September 14, 1897, he was requested by Dr. J. N. Hall to see D. R. D., aged 44 years, occupation, stone-mason. The patient gave the following history: Five days previous he was pitched from a buggy, fell near the horse, and was kicked in the face. For eleven hours he was unconscious. On the second day he discovered that he had bare light perception with his right eye. Examination revealed a lacerated wound, one inch and a half in length, extending to the bone, immediately over the supraorbital ridge. The tissues covering the right malar bone were swollen and discolored. There were also some irregular cuts in the right upper lip. There was slight ecchymosis in the tissue of the lower outer quadrant of both eyes. Action of external ocular muscles was normal. He had no light perception with the right eye. V. L. eye = %. Field for white, normal. Pupils were equal. The papillary reflex of the right eye was absent. The associate reflex of the right with the left eye was normal. The mediae were clear and the fundi normal, there being no change in the discs or vessels. Prognosis as to vision of the right eye was unpromising. Hearing: Right ear = watch in firm contact. L. ear = not in contact. Patient stated that he had not been able to hear the watch on contact with his left ear for ten years. He was able to hear the voice at the ordinary pitch with either ear. On Nov. 9, 1898, R. E., no light perception. Blue white atrophy of the right disc, absence of capillary vessels and slight narrowing of the retinal arteries. E. E. V = %. Disc, normal. At the time of the accident there evidently occurred fracture of the orbit or bony canal through which the right optic nerve passed, and with it loss of function of the right optic nerve either from laceration of the nerve, or hemorrhage into its sheath, or both. Dr. Van Hilder has examined 124 cases of fracture of the skull, in 86 of which the fracture extended into the orbital roof. In 63 of the 86, the fracture was through the canal, always through the upper plate, occasionally through the inner, or both. In 42 cases there was hemorrhage into the sheath of the nerve.

French Congress of Gynecology, Obstetrics and Pediatrics.
Marseilles, Oct. 8-10, 1898.

Pozzi extolled the benefits of scientific congresses, in which he is an enthusiastic believer, although, he observed, the best results, the real scientific gatherings of the congress, sometimes occur in the intervals between the regular meetings. He compared a congress to a bottle that has just been shaken up: Leave it alone a while, the sediment will settle and the wine can be decanted. What matter if there are occasionally dregs as long as there is so much liquor above that is worth preserving! He mentioned that France alone has no chair of gynecology or infant surgery, while even Roumania now has a model, endowed gynecologic institute. He advocated the introduction of postgraduate courses into the French universities.

President PINARD called attention in his opening address to the necessity of specific treatment of syphilitic parents, and the frequency of degeneracy among the children of parents addicted to alcohol.

LE GENDRE'S address on "Dyspepsia in Boarding Schools," stated that in spite of modern hygiene, dyspepsia is more frequent among children now than it used to be in our father's day, and seems to have a nervous or neurasthenic heredity as the foundation, and gastro-intestinal disturbances as the manifestation, frequently presenting misleading symptoms. He noted the connection between this dyspepsia and appendicitis later. He advised better hygienic arrangements, notwithstanding the wonders already accomplished; no sport carried to extremes; the time devoted to meals lengthened: reiterated counsel as to mastication; more milk and eggs in the diet; less salad, and other green vegetables; beans, peas, etc., in a purée, as the hulls are trying to some intestines. The peculiar dyspepsia due to the ingestion of bread too fresh and spongy should be carefully guarded against. More important than all is the co-operation of the family with the school. The family physician should write to the school physician and instruct him as to the tendencies of the child placed in his charge.

PERRIN discussed the "Purpuras of Childhood," which he classifies as: 1, primary, infective; 2, rheumatic; 3, Werlhof's disease, and numerous secondary infective forms.

LE GENDRE would like to abolish purpuras out of the nosology, as it is as illogical to compare them with each other as the headache in neurasthenia and in meningitis. He mentioned a case of purpura in a neurasthenic child that had resisted treatment for three years, cured with absolute rest and protracted baths.

GUINON spoke of

COLITIS IN CHILDREN.

Under three years of age it usually appears as gastro-enteritis, but after this age it resembles more the colitis of adults, and has the same foundation: a neuro arthritic predisposition. He classifies it as acute colitis, with its mucous or catarrhal form and the dysenteric and chronic colitis, which may be mucomembraneous, either indolent or enteralgic, or else paroxysmic, either simple or dysenteriform. Colitis may be confounded with appendicitis, although there is less localized pain, or with peritonitis, dysentery, typhus or tuberculosis. Complications are also frequent; furunculosis, lithiasis, broncho-pneumonia, peritonitis, etc., which obscure the diagnosis. In the chronic form the indications are to combat the neuropathic tendencies with frequent, protracted baths, tepid douches every day, avoidance of fatigue and walking, especially when there is pain. Conform to the diet to the predominating diarrhea or constipation. Milk frequently is responsible for the former. Give hot compresses to the abdomen morning and evening. Modify the intestinal putrefactions with calomel, supplemented with benzonaphthol combined with betol and bismuth salicylate or magnesia. The constipation should be kept under control. Castor-oil in small doses is the best laxative, if one is required. Gentle, cautious massage is beneficial. Others reported coinciding appendicitis and colitis, treated with water only for twenty-four to thirty-six hours, then with diluted milk and injections of serum. A case of typhus in a two months old babe was reported, in which the serodiagnosis was positive, and confirmed by the necropsy.

HOFFA discussed the subject of orthopedics and exhibited radiographs showing the fine results attained with his method of testing clubfoot, congenital luxation of the hip and scoliosis. He treats the latter by first rendering the spine flexible, with gymnastics and an apparatus, until the child can himself actively straighten the deformity to some extent. When the spine had thus become mobilized, he applies a cast to hold it in the correct position. If this method is perseveringly followed the results are very satisfactory. He has also been very successful in Little's disease with massage, passive movements

and an orthopedic apparatus. Many children who were in a most deplorable condition are now able to walk and even dance.

DUCROQUET suspends the child in the Sayre by the head alone, to reduce the hump in scoliosis and apply the cast thus in the walking position. He presses on the hump with the right hand while embracing the pelvis with the left arm, forcing it backward. He observed that it is a great mistake to expect the cast to compress the body into the correct shape; it is only to maintain what has been otherwise secured. Eschars are produced if this rule is neglected.

WEILL of Lyons discussed

HEART AFFECTIONS IN CHILDHOOD.

He said that from the therapeutic standpoint we must distinguish between functional disturbances and those due to congenital or acquired anatomic causes. There is no rational treatment for congenital heart troubles, but etiologic factors can be utilized in the prophylaxis, such as the effects of consanguineous marriages, syphilis or rachitis on the part of the mother. The preventive is also the principal treatment for acquired heart disturbances; the salicylic preparations at the slightest indications of rheumatism, cold baths in typhoid, antiseptics of the mouth in scarlet fever. In case of endocarditis, which is usually caused by rheumatism under five years, the underlying rheumatism must be cured. Compensation is more frequent in childhood than in adult life, and the physician has only to sustain it by appropriate hygiene, muscle gymnastics, food, clothing. The treatment of functional disturbances varies as they are congenital or acquired. With the congenital there is usually cyanosis and chilliness for which a warm climate is to be recommended. The various symptoms are treated symptomatically. Digitalis is given as to an adult in the required form, especially with serious asthymia, to children over 5 years of age. Under this age, caffeine, strophanthus, spartein sulphate, or convallaris majalis are to be preferred. Combined with this there should be certain gymnastics, massage of the extremities and abdomen, and chief in importance, the vibration of the precordial region and of the back, called in Sweden "digitalis massage."

BEZY reported several cases of hysteria in children, simulating peritonitis.

MOUREN stated that since he had been using artificial serum in injections for prematurely born infants his mortality had fallen from thirty-six to six in his fifty cases in 1898. He injects 100 grams three to four times during the day.

D'ARTROS stated that he had succeeded in curing chronic serous meningitis in children over 2 years old with potassium iodid and mercury, even in the absence of syphilitic antecedents.

It was announced that Lannelongue's sclerogenic method of treating inguinal hernia has been applied in sixty-two cases with remarkably satisfactory results to date.

MERY mentioned as the indications of mixed infection in diphtheria or streptodiphtheria, the abnormally high fever, worse general condition, evidences of septicemia and pyemia, suppurations of the ears, joints, glands, and various forms of hemorrhage. Diphtheria serum can be given at first in a large dose, but it is of no use after the association has developed its full effect. Antistreptococcus serum can then be used. Local antiseptics is especially important, for which Roux recommends hot water and salt solution.

EXTRA-UTERINE PREGNANCY

was the subject announced for discussion in the Obstetric Section.

SEGOND observed that every extra-uterine pregnancy, once diagnosed, demands surgical intervention. Under four months, if the other annex is likewise affected or there is a uterine neoplasm, the vaginal route is without exception the one to be preferred, but in all other cases laparotomy is indicated, and the extirpation of the fetal cyst offers few difficulties in most cases. The removal of the cyst arrests the hemorrhage if visceral lacerations are avoided. An enucleable hematosalpinx indicates laparotomy, but with an encysted hematocoele that has stopped bleeding the vaginal route is best. The sac must be extirpated with extreme gentleness and prudence. If a hemorrhage starts, the operation can conclude with a laparotomy, vaginal hysterectomy or the removal through the vagina of the entire adnexa. If the hematocoele has periodic hemorrhages, laparotomy is the only operation. In case of extensive hemorrhage (peritoneal inundation), the necessity of a laparotomy is evident from the statistics: 86 per cent. mortality with expectant treatment; 35 per cent. recoveries with an operation. Over five months with a living fetus, the attempt can be made to save the child, waiting until the seventh month, or, according to Pinard, to the eighth or ninth. In such cases the exteriorization of the cyst is sufficient, leaving the expulsion of the placenta to nature. If the fetus is dead, it is best

to wait until the placental circulation is reduced, then extract the fetus, exteriorize the cyst and abandon the placenta. The total extirpation of the cyst can be attempted in cases of tubal pregnancy, if the decortication required is not too laborious, requiring an excessive tamponing of raw surfaces, in which case total utero-annex castration is indicated. This should be reserved for the cases in which, having commenced the ablation of the fetal cyst, it is found impossible to complete it without overtaxing the strength of the patient. The tubo-Interstitial location of the pregnancy or the existence of a concomitant uterine neoplasm are also indications for total hysterectomy. He disapproves of total castration on account of possible future trouble, remarking that the woman may yet bear fine children and that even the little "ectopere" may turn out well, of which he has recently had a striking instance. Martin has met with cysts which were too friable to be marsupialized. Jonnesco believes that the other annex is almost certain to be affected and that bilateral castration is the only safe plan. Leonte of Bucharest advises leaving the pregnancy alone if all is working well, but operating at once in case of suppurative or infectious. In all cases he extirpates the entire tumor and irrigates copiously with salt solution.

Pozzi called attention to the advantages of the lateral incision such as is done for opening up the iliacus, when the tumor is located at one side of the abdomen. The fetal cyst can be thus incised without opening the peritoneal cavity. He disapproves of listening to the appeals of the woman for castration to protect her from future ectopic pregnancies.

FRANCOIS related an observation of an intracervical abscess completely obliterating the canal in the sixth month in a primipara.

DERICHE has had a patient cured of menorrhagia, with the bicycle; others of chronic diarrhea; others, using it more energetically, cured of chronic constipation. Recent radiography of some men taking part in a bicycle six-day race showed that the viscera had a tendency to assume a more elevated position, which suggests that bicycle exercise might be used to counteract a tendency to abdominal ptosis.

DUBOURG's conclusions from a comparative study of his forty-four hysterectomies for the removal of uterine fibroma or cancer of the cervix, were that the abdominal route is much to be preferred, and that its statistics will be much more favorable when it is no longer reserved for extreme cases, as is the present tendency. Two cases of recto-vaginal fistula after hysterectomy were reported, and the promptness with which they healed without further intervention emphasized.

The value of formochloral in obstetric disinfection was extolled by several.

SEDAN uses formalized soap for his hands, which kills staphylococci and streptococci, and for the patient an aqueous solution of formochloral which is odorless and does not stain the linen. For disinfecting the room one liter of formochloral to 100 cubic meters for eight hours. The commercial formaldehyde is absolutely useless, on account of its polymerization.

QUEIREL asserted that the umbilic cord is strong enough to bear 7 to 10 kilos, and that, even with a macerated fetus, it is seldom that the weight of the fetus can break the cord (118 cases).

RICHELOT treats

RETROVERSIO UTERI

with pessaries and bandages, massage or hysteropexy. In simple cases a pessary may prove sufficient, but it is usually a delusion. Massage is much better, detaching adhesences, relieving congestion and especially valuable in cases complicated with infection. The uterus must be healthy, a metritis cured, before surgical intervention should be attempted. Abdominal hysteropexy is a fine operation, curing many women and favoring conception. The threads must be applied exclusively in the anterior surface of the uterus, below the tubal openings. Certain cases are best treated with vaginal hysteropexy, but Martin and Pozzi object that this should only be performed on women past the menopause, adding that this operation is falling into disrepute generally. A case of non-puerperal osteomalacia treated with ovariectomy was reported. The ovaries were found much atrophied, with macroscopic cysts.

MANGIN has found ligating the uterine arteries a successful measure to control uterine hemorrhage rebellious to all other treatment. The only absolute counter-indication is a lesion of the annexes.

FOCHIER reported three cases of phlegmasia alba dolens rapidly cured with abscesses produced with spirits of turpentine. MERIEL has found pencils of equal parts of methyl salicylate and arol .1 gm. very effective in endometritis.

MARCEL BAUDOUIN proposed a classification of operations on the uterus, based on the decimal system in use in libraries.

PRACTICAL NOTES.

Calomel Injections in Lupus.—Thirty-eight cases have been reported cured or very much improved by this treatment, and ten not affected to date.—*Munich Med. Woch.*, November 15.

Ichthyol Stains on Linen.—Javelle water (potassium hypochlorite) will readily remove ichthyol stains from linen.—*Munich Med. Woch.*, November 8.

Aromatic Cod-Liver Oil.—According to Duquesnel, the odor and taste of cod liver oil can be disguised entirely by the following formula: Ol. jecoris. flav. 150 gm., ol. eucalyptus. ether gtt. ii.—*Munich Med. Woch.*, November 15.

Trifacial Neuralgia and Migraine.—Apply, locally, a tampon moistened with the following: sulph. ether 50 gm., melissa alcohol 50 gm., menthol 20 gm. The pain vanishes with the refrigerating effect produced, and relief is experienced for hours.—*Gaz. Méd. de Liège*, November 13.

Gluten Capsules.—Bely utilizes the property possessed by gluten, of not being affected by the gastric secretions, to make a capsule of it for the administration of creosote. He prefers the formula: pure creosote 15 gm., balsam of tolu 05 gm., lime glycerophosphate 05 gm.—*Journ. de Méd. de Paris*, November 13.

Trichloracetic Acid in Tympanic Perforations.—B. Miot reports forty-nine successes in fifty-one cases of perforation of the tympanum by Okuneff's method of etching the edges of the perforation with trichloracetic acid to induce cicatricial obstruction of the hole. If the edges are refractory to the action of the acid, he recommends radial incisions or galvanocauterization to freshen them.—*Chl. f. Chir.*, October 29.

Bacteriology of Accidental Wounds.—A study of 222 wounds demonstrated that there were only 17 sterile, and that most of the microbes found were clinging to the blood clots. Copious rinsing is therefore urgently indicated to remove as many of the germs as possible by its mechanical action. Airol or iodoform gauze for an antiseptic tamponade was found most effective in infected wounds, or bismuth oxyiodid.—*Chl. f. Chir.*, October 29.

Bacteriologic Investigations in Diphtheria.—The process is rendered easier and shorter by Schottelius' suggestion that the cotton stopper to the test-tube have a stiff wire loop extending below, to the end of which another piece of cotton is attached. With the stopper for a handle the throat is wiped with the cotton on the end of the loop, which is then inserted into the test-tube, the stopper closing it, the whole placed in a paper tube closed with a cork, enclosed in an envelope with the address printed on it and sent to the Institute. The entire contrivance is supplied by the Freiburg Institute for 25 pfennige.

Modern Treatment of Migraine.—Most cases of migraine are due to intoxication, auto or exogenous, and the indications are to regulate the organic changes, increase diuresis and diaphoresis. Quinin, antipyrin, acetanilid and phenacetin are absolutely contraindicated, as they diminish the organic exchanges. Salicylic acid is an exception, but the increase produced at first is followed by a decrease, and it can not be used long at a time. The measure which fulfills all conditions is a vapor bath or prolonged pack followed by cold applications, combined with an appropriate diet.—*Stekel: Rev. Gen. de Path. Int.*, November 5.

Mechanical Stimulation of the Skin.—F. Lots describes (*Ztschr. f. klin. Med.*, xxxv, 2) his success in curing or remarkably improving a number of nervous affections, with friction with a loofah, of one member at a time, for ten to twenty minutes, two or three times a day, the patient in bed, supplemented by running around barefooted on pebble stones spread on a blanket on the floor of the room. The pebbles are about 1 cm. in

diameter and are well rounded. The sensation is not disagreeable after the first day or so. The feet become warm, the appetite and intestinal peristalsis are increased, while the general condition improves in every respect. His cases included 11 of neurasthenic cephalaea; 2 of nervous children with a tendency to chorea; 2 of general nervousness in adults; 3 of intermittent pulse; one case of incipient and one of advanced tabes.—*Munich Med. Woch.*, November 15.

Heroin in Coughs.—Manges of New York, in the *New York Medical Journal* of November 26, presents his experience with this drug in the treatment of coughs. In a few cases he found disagreeable after-effects, with the symptoms complained of referred to the sensorium. These symptoms were, however, much more mild and far less frequent than after morphin or iodine. In the aged, not more than twentieth-grain doses are to be given, as they bear the drug poorly. The drug allayed coughs promptly and efficaciously in numerous cases, though in some one-sixth of a grain was necessary. The results were not so good in purely neurotic coughs. The only case where no relief was secured was one of dyspeptic asthma, though other asthma cases gave good results. The results were not uniform in pulmonary tuberculosis, but were better in the early stages, smaller doses being necessary for later stages.

Home Treatment of Chronic Morphiaism.—Hirt of Breslau has cured twenty-seven out of thirty-five cases. Two committed suicide during the first three days, when the morphin is absolutely denied; the remaining five either relapsed or failed to complete the cure. A reliable attendant is indispensable, and he adds that only a female attendant will answer. During these first three days the patient is kept asleep with 3 grams of chloral or trional, and a bath at 27 to 28 degrees C., with a cold douche, if the sleep is agitated. After three or four days a suggestion-therapeutic treatment is commenced, first extending only to the drug itself and its dangers, and then including the patient and inspiring him with fear and abhorrence of its effects. He only attempts to treat patients whose daily dose is under 0.75.—*Therap. Monatsheft*, 10.

Counter-indications to Breast-feeding an Infant.—Tuberculosis is an absolute counter-indication; with many other diseases the question is not so much the nature as the severity and degree of the affection. Anemia is a relative, the different cachexias positive, counter-indications. The general condition is the guide after an operation has been performed on the mother. Local counter-indications are affections and malformations of the nipples, which can not be remedied with cocain, artificial nipples, etc. Epilepsy, chorea, psychoses, are counter-indications on account of the danger of accidents to the child. Hereditary syphilis is a formal indication for breast-nursing. The quantity and quality of the milk may prove counter-indications; the milk of certain women has a purgative, toxic effect. The passage of toxic medicines and infective germs into the milk must also be borne in mind. The child should be isolated when the mother alone has a contagious disease. Nursing is permissible in localized puerperal infection, but the lacteal secretion fails in general infection.—*Journ. de Méd. de Paris*, Nos. 35 and 37.

Argil for Dressing Wounds.—J. Stumpf describes (*Munich Med. Woch.*, November 15) his surprisingly favorable results obtained with the copious application of dry argil to wounds of all kinds, which heal under it without the slightest reaction. Even the suture threads pull out dry without in the least sticking. The absorbing power of the clay is most remarkable, as evidenced by numerous tests he reports, such as wadding a little cotton, very wet with water and defibrinated blood, and rolling it around in some clay for fifteen or twenty minutes, when it will be found so coated with clay that it is practically a heavy clay ball. Broken open, the wad of cotton drops out

like the kernel of a nut, perfectly dry. All the moisture has been absorbed into the clay shell. He relates a number of instances in which crushed hands, suppurating ulcers, and even ozena, treated with the dry clay first lost all odor and then healed in the most aseptic conditions. He applies it to an "unfingered" wound without further infection, using the ordinary commercial article, heated by the druggist to 150 degrees C. Meat or slices of liver laid in the clay harden rapidly to a brittle, mummified substance.

Technique of Intravenous Injections.—An intravenous injection is almost entirely painless, differing in this respect from the subcutaneous. It works more rapidly and energetically and is especially valuable in severe forms of syphilis. Experience has demonstrated that the fear of embolism and infection were unfounded. Several injections can be made into the same vein. The needle is inserted perpendicularly, then the point turned toward the root of the member, the needle unscrewed to prove by the flow of blood that it is actually in the vein, then the ligature above is unfastened, if one has been tied, to render the vein more distinct. The prick through the skin is all that is felt. The needle is left a moment afterward to allow the injected fluid time to be carried away by the circulation. If the injection is painful, the needle must be in the tissues instead of in the vein. First proposed by Baccelli, Abadie is now introducing the method into France. The formula used is one part mercur. cyanat. to a hundred parts dist. water. One c.c. is the amount for a single injection. They are made every day or every other day, according to the severity of the case. Fifteen to thirty are usually the limit of treatment required.—*Riforma Méd.*, 1898, p. 203.

Vaginal Abdominal Section.—Löhlein has found this operation extremely satisfactory in a number of cases (forty-two during the last two years). The trauma and the possibility of infection of the peritoneum are very much reduced. The patient feels subjectively well from the first, afterward. The easy and thorough evacuation of all fluids in the peritoneal cavity, and the possibility of combining with it a number of other interventions on the perineum, vagina, etc., recommend this operation. The difficulties liable to be encountered are a narrow or rigid vagina, solid consistency of the morbid products to be evacuated, and impossibility to reduce their size by puncture and detaching parts. A ligature became unfastened in three cases, requiring the application of forceps for thirty-six hours. In a number of cases he was obliged to complete the operation with laparotomy, for which reason he advises that the abdomen should always be prepared beforehand as for laparotomy, as well as the vagina. In one case the ovary was removed through the posterior vaginal incision, without interrupting pregnancy. He has been especially successful in peritoneal tuberculosis. The operation was performed once to differentiate carcinoma from tuberculosis.—*St. Petersb. Med. Woch.*, October 29.

Avoidance of Splints in Colles' Fracture.—Mr. Jonathan Hutchinson has encouraged his house surgeons at the London Hospital to treat cases of Colles' fracture without splints. His instructions were never to put on splints unless there was displacement which could be removed by extension, and which returned when extension ceased. In such cases, a very small proportion only, splints are indicated, but they ought not to be kept on long. If the routine treatment by splints was laid aside it would be greatly to the advantage of patients and to the credit of surgeons. In many cases treated in the orthodox way, the wrist and fingers become stiffened, and the hand often becomes painful and useless. Nineteen-twentieths of these cases would have done well and escaped stiffening if the wrist had been kept between two cushion pads for a fortnight. The public, as well as the profession, seemingly think that there is a necessary connection between a fracture and a splint. If one reflects

on the real condition present in Colles' fracture, the truth of these remarks will be evident. In many there is no displacement whatever, and no movements of the patient could produce any. In others there is displacement of the carpal fragment backward to the radial side. If this is present, and can be removed by extension, and returns when extension is remitted, then a splint is necessary, but not otherwise.—*Med. Rev. of Rev.*, October.

Intestinal Surgery: Use of Murphy's Button.—Mr. Frederick Treaves of the London Hospital has had an experience with Murphy's button in fifty to sixty cases. In his opinion, of the various appliances for uniting the divided bowel, the button is the best; not that it can be regarded as a perfect instrument, but it compares favorably with the other forms of apparatus having the same object. He quotes Chelius to show that a French surgeon named Denans, sixty-two years ago, offered a procedure which prefigures the Murphy button; in Denans' procedure he "introduced into the upper and lower end of the divided gut, a silver or zinc ring, thrusting it inwards about two lines from each end; he then brought the two ends together over a third ring, of which the two springs retain the external rings. The included ends of the intestine mortify and the rings thereby becoming unfastened are discharged by stool after they have united the serous surfaces in contact." The results following the use of Murphy's button are certainly satisfactory. The button requires no elaborate preparation; it is always ready; its introduction is exceedingly simple, and is effected in a few minutes. The two parts of the instrument may certainly jam, but that accident is the result of careless handling. He has never known it to induce a gangrene which has extended beyond the limit of the button. The two definite and undoubted objections to the button are these—it may be indefinitely retained, and its separation may be followed by contraction at the artificial opening. In only two cases of gastro-enterostomy performed by Mr. Treves did the retention cause any trouble. In one case the button did not leave the stomach for a year, and the surgeon did a second operation for its removal; a skiagram having shown very clearly that the button was still in the stomach. As an example of the contraction of the colon that may occur after the use of the button, Mr. Treves instances the following case: "A man, aged 61 years, who had had symptoms of chronic intestinal obstruction for some months, was seized with symptoms of acute occlusion of the bowel, attended by immense distension of the abdomen and stercoraceous vomiting. Laparotomy, performed in January, 1897, revealed an epithelioma in the center of the sigmoid flexure. The urgency of the case and the great distention forbade any attempt at excision. I therefore effected an anastomosis, by means of a Murphy's button of the largest size, between the two extreme ends of the sigmoid flexure. The diameter of the button was $1\frac{1}{2}$ in. Fluid feces were passed before the patient left the table and he was at once relieved. The button, which had already been used in two previous cases, was passed on the twenty-second day. The patient was walking out of doors at the end of the fourth week. In March, 1897, he had regained his original weight and his bowels were acting well with aperients. I then performed a second laparotomy to remove the sigmoid flexure. Although only thirty-eight days had elapsed since the passing of the button I found the artificial opening I had made so contracted that it would do no more than admit my little finger. I removed the whole sigmoid flexure and united the descending colon to the rectum by means of the same button. This button was passed on the sixteenth day. The patient recovered rapidly and remains in sound and vigorous health. This association between previous distention of a viscus and the subsequent contraction of the aperture made in it, is, of course, by no means limited to Murphy's button. It applies to nearly every method in vogue for carrying out the operations now under discussion. Still, in spite of many drawbacks and many failures, intestinal surgery has made within the last few years decided and substantial advances; but it will fall short of perfection until antiseptic surgery, which has so far penetrated only to the serous covering of the gut, has reached the mysterious and septic lumen which lies within the bowel wall.—*London Lancet*, November 5.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheet returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, DECEMBER 10, 1898.

THE PRESIDENT'S MESSAGE.

The President's message again recommends the commission of experts asked for by the American Public Health Association, and it is sincerely hoped in medical circles that a certain Washington Bureau will kindly permit Congress to act on the recommendation of the President without too much opposition.

In my last annual message I recommended that Congress authorize the appointment of a commission for the purpose of making systematic investigations with reference to the cause and prevention of yellow fever. This matter has acquired an increased importance as the result of the military occupation of the Island of Cuba and the commercial intercourse between this island and the United States, which we have every reason to expect.

The sanitary problems connected with our new relations with the Island of Cuba and the acquisition of Porto Rico are no less important than those relating to finance, commerce and administration. It is my earnest desire that these problems may be considered by competent experts and that everything may be done which the most recent advances in sanitary science can offer for the protection of the health of our soldiers in those islands, and of our citizens who are exposed to the dangers of infection from the importation of yellow fever. I therefore renew my recommendation that the authority of Congress may be given and a suitable appropriation made to provide for a commission of experts to be appointed for the purpose indicated.

THE NORTH-WEST FRONTIER DISTURBANCES
IN INDIA.

From an official report we gather some items of information concerning the medical provision for the troops engaged with the hostile tribes from June 19, 1897, to April 6, 1898, which may be of interest at this time when we are investigating what was done

and what was not done for the care of our sick and wounded during the Spanish War. The corps units mobilized consisted of sixteen batteries of artillery, nine regiments of cavalry, ten companies of sappers and miners and fifty-nine battalions of infantry, aggregating 18,688 British officers and men, 41,677 native officers and men and 32,696 followers, giving a total of 93,061. The medical arrangements included fourteen British and twenty-two native field hospitals of 100 beds each, a total of 3600 beds. There were no regimental, battalion or battery hospitals. There were in addition to the accommodations of the mobilized field-hospitals, 6725 beds available for use at base or general hospitals. The medical and hospital personnel consisted of no less than 9658 men, or over 10 per cent. of the command, followers included.

There were 41,055 men admitted to sick report during the nine and a half months and 1602 deaths, the admissions being at the rate of 451.70 and the deaths at the rate 17.20 per thousand of the strength. Between June 28 and Dec. 27, 1897, the average percentage of sick among the troops in the field was 4.58, the minimum rate at Kohat-Kurrum, 1.52; the maximum rate at Peshawur and vicinity, 10.52. Very great attention was paid to the sanitary state of the various posts and camps by the medical officers, and as a rule their condition was remarkably good. The weekly sanitary inspections were carefully made, and especially with a view to the detection of incipient scurvy, which was entirely absent from the British troops. The few cases which occurred among the native troops and followers were very mild. The rations were good, the clothing suitable and the water-supplies safe-guarded as far as practicable. Quinin was used as a prophylactic when considered desirable.

SICKNESS IN THE BRITISH SOUDAN FORCES:
A COMPARISON.

There has been so much denunciation of the sanitary conduct of the war that it is hoped is now over, and some of it undoubtedly based on real defects of management, that we have almost come to accept it as, in this respect, a terrible example of how such things ought not to have been done. In this country we reverse the practice of everywhere else and publish all our errors and deficiencies, so that all the world knows them; there is no limit to the scandalous chronicles given out, often without judgment or basis of truth. Elsewhere public policy and national pride tend to suppress disagreeable truths, and there is no such wholesale newspaper criticism of everything that can by any possibility be made to show a bad side.

The recent Egyptian campaign, in which Great Britain has just been so successfully engaged, has been held up to us as a model of excellence in everything that pertains to the sanitary management of a campaign, and to a large extent the praises are undoubtedly deserved. The perfect fairness of the com-

parisons that have been made to our discredit is however more than dubious. In the one case we have military operations long planned and prepared for, carried on in an arid country where germ infection must be at a minimum, and yet nowhere far from a base where by navigable river or railway every needed requisite could be obtained. The operations were carried on in a torrid climate it is true, but the bulk of the force was native, and the greater portion of the European contingent were experienced troops and had been acclimated to a certain extent by years of residence in lower Egypt. There were no special endemic diseases, like yellow fever, to contend with, no heavy tropical rains and muddy roads to interfere with transportation and render the distance of even a few miles a formidable journey, no dense tropical vegetation and malaria-breeding marshes—for a war in the tropics the conditions may be said to have been in every way exceptionally favorable. It may be added, that the English military are of all other fighting forces the ones most accustomed to tropical campaigning, and the administrative departments of the English army should be the best prepared at all times for its exigencies.

If we take up now the conditions of our own recent war we find nearly every condition reversed. With a war improvised to meet a popular sentiment, green soldiers, officers and men, transformed in a day from peaceful citizens, a little nucleus of a regular army, all the administrative departments of which, medical and otherwise, called at short notice from out of the ruts of more than thirty years of peace, and their tasks and responsibilities tenfold increased, no long careful preparation, and hardly any traditions even of tropical warfare and its requirements to guide their operations, it is little wonder that mistakes were made. Add to this the fact that the military operations of the Santiago campaign were carried on in a miasmatic tropical region, during the rainy season, when the climate is deadly to the unacclimated whites, the dense vegetation, the tropical rains and the total lack of good roads, and therefore of inland transportation facilities, and lastly the presence of the dreaded yellow fever, the wonder is not that the hardships and mortality were so great, but that they should have been so little. The comparison between SIR HERBERT KITCHENER'S successful Soudan campaign and that of Santiago should take in all these facts and then it would be far less disadvantageous in some respects.

Even as it is, we find some points where the vaunted excellence of the British military sanitation is not so evident, or, at least, where even their thorough methods were not altogether effective. In the *British Medical Journal* of October 22 we find the statement that reports in private correspondence state that sickness has been fearful among the English Soudan troops, "although the papers, save the *Chronicle*, say little or nothing about it." Cairo hospital is said to

have been so full that about October 4 most of the sick had to be cared for under canvas. It is further stated that "the mortality during the campaign from enteric fever (which is now following the troops to Crete) will probably be found, when full reports are received, to be excessive. In the same journal a week later (October 29) we find the statement that since the return of the First Battalion of the Grenadier Guards to England typhoid cases have been abundant. One hundred and sixty men, altogether, were in hospital, many of them well-marked typhoid cases. Assuming that the battalion comprised some 800 to 1000 men—rather less than more after a campaign—this would make a formidable percentage, fully equaling that of some of our green volunteer regiments on their return from Cuba, where they had the special disorders of malaria and yellow fever also to combat. On the basis of these statements it would appear probable that typhoid fever was even a greater scourge to the British troops in the Soudan than to our own forces in the training camps and West Indies. Why this should be so is not perfectly clear, unless we are to suppose that the disease was contracted in the Delta and carried up the Nile, as the Upper Nile valley with its scanty population ought not to be a breeder of typhoid. Perhaps we may yet learn that the germ of typhoid is everywhere indigenous and only requires the favorable circumstance of an assemblage of men living under army conditions to make its presence known. It has certainly come well to the front as a modern military disease, and one that requires more attention as such than it has previously received. The fact that in the late Soudan campaign all the experience and foresight of former tropical warfare could not, under apparently especially favorable conditions, prevent its ravages to any appreciable extent bears witness to this need.

Our own experience in this special regard does not appear by comparison, much worse than that of our English kindred, and this disorder eliminated from consideration, it can not be said that the sanitary record of the late war is much worse than ought to have been inevitable with our unreadiness and inexperience in military operations. There is no use, evidently, in making comparisons to our disadvantage as regards this one form of possibly preventable military disease.

THE BROWN-BREAD DELUSION.

One after another the instincts of primitive humanity are getting an unexpected endorsement from modern science. Children always had the indecency to cry for sugar and to appropriate fruit wherever found, in spite of generations of alleged "hygienic" rebuke, which was really based on the good old Puritanic principle that because they were nice there must be harm in them somewhere. Now, distinguished pediatricists assure us that next to proteids, they are the most

important elements in the diet of budding humanity.

For centuries past the great dietetic struggle of the laboring man, master or workman, has been to get white bread for his daily diet. In all the old manuscripts we find the "fayre white lofe" alluded to as the choice delicacy. All the time his self-styled "betters," whether social or scientific, have united in assuring him that his daily brown or black loaf, whether of rye, oats, barley, peas or whole wheat was much more nourishing and wholesome. He never questioned their correctness, but he continued to prefer white and the more of it the better.

Many of us can remember the new backing which was given to these hygienic views some thirty years ago, about the time that "dangerous thing," a "little knowledge" of chemistry began to be diffused abroad. Their correctness was demonstrated beyond possibility of doubt, we were triumphantly assured, for had not chemic analysis, the new infallible Pope of science, revealed that brown bread was far richer in nitrogen, that greatest desideratum of all foodstuffs? White bread might make fat, but it was brown bread that made bone and muscle. Exploiters were quick to see the opportunity, and forthwith amid flourish of pseudo-scientific trumpets the great "Graham" crusade was launched, for the physical, mental and moral regeneration of humanity by the exclusive use of whole-wheat flour. By gems we were to be saved. The physical degeneracy of our working classes was fully accounted for in mothers' meetings by ascribing it to an excessive indulgence in white bread and tea. The whole horde of dyspeptics, whose name was legion, as this new spirit entered into them, rushed violently down a steep place until they landed upon a blameless diet of Graham crackers and hot water. Here they endured for a season the outcry of their rasped intestinal epithelium and hungry muscle-cells, in the sublime faith that they would have been much worse had they persevered in their former excesses of hot biscuit and pork. Ultimately, however, they were drawn to the conclusion, that although it might be better for their dyspepsia it was worse for them, and here the first absurdity of the hasty "scientific" conclusion was demonstrated by bitter experience. This was that it had failed to take into account the irritating effect of the hard, chaffy particles of husk, which contained the precious nitrogen, upon the gastric and intestinal mucosa. Fifteen years ago "brown-bread gastritis" was a recognized clinical type in some of our great hospitals, and our Philistine profession sent forth a counterblast to the effect that not more than three-fifths of the daily bread was under any circumstances to be brown, or evil results would surely follow, and as most of the enlightened had already backslidden to about this Laodicean position, they were obliged to sadly accept the edict and acknowledge that the new gospel, like many others, was too high to be lived up to completely. Still if it were not for the irritating qualities

it would be the ideal food, and even these defects were turned to account in recommending it as a remedy for constipation, in addition to its other good qualities. For some reason or other, however, the consumption steadily decreased, every family, every class, every nation kept on discarding brown or black bread and substituting white as fast as they could afford it, and even the emancipated *illuminati* found themselves going back to the flesh-pots of Egypt and living without shame upon the white bread, the corn-meal mush, the flannel cakes of the common herd, who had no better guide than their mere appetites. The brown loaf still lingers upon the board, but rather after the manner of the mummy at the Egyptian feast, a tribute to a vanished ideal rather than an article of diet.

And now comes LAUDER BRUNTON with one of those admirably shrewd table reports of his, full of the practical genius which has made his name famous, and completely demolishes the fancied nutritive superiority of this "ideal food." His line of investigation was two-fold, first as to the actual nutritive effect upon animals of graduated exclusive diets of white and of brown bread; second as to the exact form in which the excess of nitrogen was present. The first group of experiments resulted in conclusively proving that although more nitrogen was present in brown bread, less of it actually got into the blood than from a similar weight of white bread; that white bread was not only more digestible and less likely to cause gastritis, but more nutritious, weight for weight, than brown. The second series showed the physiologic and chemic wherefore of the results of the first, inasmuch as the boasted excess of proteids was found to be chiefly in the form of the husk, or skin of the wheat-berry, closely allied to woody fiber, and absolutely insoluble in the intestinal fluids. Dr. BRUNTON pithily remarks that if nitrogen were all that we required, regardless of its form, we could grow fat upon air. He concludes by pointing out that it is precisely the stimulating effects of these insoluble and rather irritating ligneous particles upon sluggish bowels which give brown bread its well-established value in constipation. And as it is slightly richer in fat and distinctly so in lime and other salts than white, it would have certain advantages where the diet was deficient in these substances. But as our heaven-born, instinctive preference for white bread is almost equalled in strength by another for plenty of butter on it, the small fat and salt superiority of brown bread can cut but little figure practically.

We believe that the conclusions of this report will be endorsed by the practical experience of most general practitioners who have given careful attention to the diet of their patients. They found out long ago that their cases did not thrive so well on diets containing too much brown bread or "whole-meal" compounds, and will be rejoiced to find this fact explained upon chemic grounds. LAUDER BRUNTON has rendered

the profession a most valuable service by reporting his ingenious experiments. But it is worth noting that the hard-earned experience of the "man who carries the gun" in the army of medical progress, the family physician, had led him to precisely the same conclusion, and before that the untutored instinct of the natural man had reached the same goal.

Our instincts are the crystallized experience of thousands of preceding generations, and we are rapidly coming to respect them as such in these latter days.

THE LUXATION OF LARGE JOINTS IN THE COURSE OF INFECTIOUS DISEASES.

While it is a well-known fact that changes of greater or less degree frequently occur in the various joints of the body during the course of a large number of infectious diseases, it is not generally known that sometimes complete dislocations take place as the result of the progress of one of these maladies. From the time at which a swelling or disease of a joint was supposed to be due to a distinct local condition to that in which it was regarded as being entirely the result of a rheumatic or gouty taint, we have been continually learning that almost any infecting micro-organism which usually produces localized lesions in other portions of the body, may, if it finds favorable conditions for its growth in the joint, produce arthritic change. Thus we have the arthritic changes of purpura, of pyemia, of acute rheumatism, of the acute epiphysitis of infancy, which is practically an arthritic alteration, and the alterations which occur in rheumatoid arthritis. In addition to these conditions, which seem to arise from a direct infection of the joint, or parts adjacent to it, it is necessary to note that far greater lesions may occur than the inflammatory processes usually met with in the conditions we have named, and therefore a paper which has recently been published by COLLIER in the *British Medical Journal* for Oct. 15, 1898, in which he reports two cases of dislocation of the hip-joint following scarlet fever, is of interest. In the first there was suppuration in the neighborhood of the right hip-joint, but no evidence of bone disease, but dislocation of the right femur upon the dorsum of the ilium took place, necessitating an operation eventuating in a recovery in ankylosis with slight flexion. In the other case, also of scarlet fever, there was a history of injury on the fifteenth day of illness in that the patient fell out of bed upon his face, but it was not until a week later that any trouble with his joint was recognized. In this instance dislocation of the right femur of the sciatic variety occurred, and although reduction followed extensive myotomy, three years afterward shortening of half an inch in the length of the leg was present.

These cases of dislocation during the course of grave illnesses are of very great interest from the medical point of view, and of still more importance

from a medico-legal aspect. As is well known, dislocations have been recorded in considerable number as having occurred during the progress of typhoid fever and acute rheumatism. In the first of these diseases the displacement of the bone has occurred in the earlier days of convalescence, when the patient has been so feeble that it has seemed as if the accident was due to the relaxation of the coverings of the joint and its associated muscles, with the result that the bone has easily slipped out of place, and in nearly all these cases there has been no evidence whatever of any local difficulty prior to luxation. On the other hand, in acute articular rheumatism where dislocation has taken place, there has nearly always been a history of arthritic difficulty prior to the accident, and instead of the dislocation producing pain of a moderate degree, as it has done in convalescence from typhoid fever, the occurrence of the displacement has been followed by great relief from pain owing to the overcoming of the vicious attitude which has been maintained by the limb. The cases of scarlet fever in which this accident has occurred have belonged rather to the typhoid class in that the dislocation has taken place without much pain and therefore without attracting great attention to its presence. As long ago as 1882 RAWDEN reported in the *Liverpool Medico-Chirurgical Journal*, an instance of dislocation following typhoid, in which having excised the head of the bone, he found it practically normal, even the cartilage being healthy, excepting for a little absorption at its periphery, while on the other hand ADAMS in a case of rheumatic dislocation of the hip found the capsular ligament ruptured and the torn margins of the rent closely embracing the neck of the bone. While it is true that unobtrusive monarticular synovitis with effusion may take place in convalescent patients, the literature of the subject does not reveal the fact that post-typhoidal dislocations have usually been due to this condition, and COLLIER believes that degenerative changes similar to those seen in muscular fibers result in softening of the ligaments and of their attachment to the bones. The possibility of recurrence of the dislocation under such circumstances is great, and the prognosis as to the correct use of the limb must be made with caution, since some cases seem to become entirely well while others never get rid of a certain amount of ankylosis or shortening.

CORRESPONDENCE.

Buying Patients.

HARTFORD, CONN., Dec. 1, 1898.

To the Editor:—Recently a physician who has attained some prominence in his neighborhood, wrote me asking what I was accustomed to give the family physician who sent his patient to my care. I replied that I never bought practice and never gave anything to physicians who sent me cases. He answered that he always received a fee of \$10 for sending cases who could pay \$20 and more a week. Where the bills amounted to

several hundred dollars, most medical men sent him 5 per cent. on all accounts over \$200. From inquiries I found that two gold cure establishments had received some cases from this physician and an obscure New York specialist had also received and treated some cases sent by him. Within five years, since the prominence of "gold cures," I have heard of offers of this kind from managers of such places. In all my long experience with the profession, I have never before been approached by a reputable man, and I am confident that a very few medical men would ever stoop to buy or sell patients in this way. The real specialists, who depend on the profession for their cases, feel bound to the medical man to return the case to his care again with renewed confidence of the skill of the family physician. A kind of unwritten law has grown up, in which the specialist assumes the care of the case for a time, and expects to return it to the care of the family physician for further and more protracted treatment. In my experience in the care of alcoholic and opium takers, after a few months' residence in an asylum, the return to the family or general practitioner is a very essential part of the success of every case. The best results come from the general after-cure by the physician outside of the asylum. The case is sent to me by the physician for such care as he can not give at the time and place. When the acute symptoms subside, and restoration begins, it is often better to go back under the family physician's care. In all this the specialist acts as a consultant and has no claim on the patient, nor is he under any special obligations to the physician who sends the case. The physician is rather under obligations for the favor of special treatment, and return of the case to his care again. The idea of buying and selling the privilege of treating the case is repulsive to all sense of honor and professional courtesy. The physician sends his case to the specialist simply because it is the best interest of his case. No other course should receive the least attention.

Very truly,

T. D. CROTHERS, M.D.

The Commission Evil.

MINNEAPOLIS, MINN., Nov. 30, 1898.

To the Editor:—The editorial in the *JOURNAL* of November 12, on the "Commission Evil," sounds very much as though the writer had stumbled upon the unpleasant fact that some of his friends were engaged in the disreputable practice mentioned. The protest seems a very mild one if the evil is as wide-spread as the writer claims. Dr. Morris' communication in the last issue (*vide JOURNAL*, p. 1314) affords the pleasant assurance that specialists in the East are still in sight, at least, of the ancient traditions. Unfortunately some of our western towns have become so infected with this evil that no honest, self-respecting specialist would dare make the effort to establish himself if he knew the facts. For the past few years, in this city, a patient with an eye bandaged could not walk our down-town streets without being approached by runners with the offer to take him to a better surgeon than the one he was employing. I do not know how many general practitioners are willing to accept bribes, but the fact that advertising quacks find it profitable to send circulars to the profession, offering commissions on all business sent to their surgical, lying-in and other hospitals, is very suggestive, and the fact that men known to be guilty of employing runners are gilt-edged candidates for any position in the gift of their professional brethren, does not indicate such a puritanic state of mind on the part of the latter as would blind them to the glitter of a dishonest dollar. The specialist who fees the runner or the family physician; the insurance examiner who divides his fee with the agent; the surgeon who operates cases for the advertising quacks; as well as the dishonest family physician who betrays his trust, are the parasites of our profession. I

congratulate Dr. Morris on living in a community where such men are not the *leaders* of the profession.

EDWARD J. BROWN, M.D.

Gold Cures.

HARTFORD, CONN., Nov. 28, 1898.

To the Editor:—In my paper on "Gold Cures in Inebriety," in the *JOURNAL* of October 1, no reference was made to any combination of gold with other drugs for any diseases beyond inebriety. The managers of mercuro and arsenuro, well-known combinations of mercury and arsenic with gold, have misconstrued my statements to be reflections on their preparations. In this they are very much mistaken; no possible criticism was, or could be intended, and more especially as I have used this prescription in many cases with good results, and have repeatedly spoken of it in the *Journal of Inebriety*. My criticism was directed only to specifics of any form which sought to bring about results known to be impossible.

Very truly,

T. D. CROTHERS, M.D.

PUBLIC HEALTH.

Mouse Typhus.—The Austrian government has made arrangements to exterminate the mouse pest in lower Austria by inoculating mice with Loeffler's mouse typhus bacillus.—*Munich Med. Woch.*, November 8.

Pellagra in Italy.—We note in a recent report that sanatoria are being erected in different provinces to treat this disease. Persons affected are compelled to enter and remain forty days, in Padua twice a year. Malaria is the most serious complication of pellagra. It is hoped that the circular of questions submitted to each patient will in time throw some light on the obscure etiology of this affection.

Deaf and Dumb in Norway.—V. Uchermann has recently compiled the statistics of all the deaf and dumb persons in the entire country, with objective data in most cases. Half are congenital defects. Of the cases of acquired deafness, one-fourth were consecutive to scarlet fever, the rest mainly to cerebral and middle ear affections. The influence of heredity is marked, especially the heredity of consanguineous marriages, although the inheritance of deafness and dumbness frequently alternates with other abnormalities, idiocy, epilepsy, malformations, retinitis pigmentosa, etc. He attributes the preponderance of deaf and dumb children in consanguineous marriages to the accumulation of family peculiarities.—*Cbl. f. Chir.*, October 29.

Sulphurous Acid in Preparation of Fruit for Market.—As many hundreds of physicians are directly or indirectly interested in fruit culture, the following item from the "Consular Reports" (November) will convey to them a much needed line of information. The item is contributed by Consul Barnes at Cologne, Germany. "Persons interested in the exportation of American fruits to Germany strongly desire to remove all reasons for obnoxious official investigations, and have requested me, through the Department of State, to call the attention of the American shippers to this condition of affairs, and to the absolute necessity of abstaining from the use of sulphurous acid, or any such preparation, in the exportation of fruit to this market. A persistence in this practice will undoubtedly result in the entire exclusion of such fruits from Germany. Stricter attention must be given to the German laws. American dealers are still shipping to this market dried-apple slices which have been cured upon zinc frames. This process has been strongly condemned by the German Government, and the sale or handling of fruit thus prepared interdicted by law. These violations are suicidal in their effects, and damaging to the several branches of American trade. It is the opinion of

importers here that in some instances American pears are also treated with the sulphurous-acid process. It is of no consequence that competent medical authorities here have decided that fruit treated with sulphurous acid is not detrimental to health. It is sufficient for the watchful local official to know that the law forbids the sale of such fruit, and that his supreme duty consists in the strict enforcement of the law as he finds it upon the statute books. American fruits are so far superior to other fruits found in this market that it would seem an easy matter to dominate the trade, without a resort to practices which tend to discredit them."

Masks for Non-Isolated Tuberculous Patients.—B. Fraenkel has inaugurated, at the Berlin Charité, the innovation that all the tuberculous inmates must wear masks to catch the germs they expel in speaking and coughing, when they are in the common room, and only remove them while eating or expectorating. The patients soon become accustomed to the mask, as by impregnating it with some medicinal substance they suppose it is to be worn for their own personal benefit, instead of for the protection of others. Bacilli are frequently found on them. At the Dettweiler sanitarium the patients are trained not to cough when assembled at meals. Schäfer found that a leprosy subject with ulcerations in his mouth scattered leprosy bacilli through the room in conversing. One of Fraenkel's assistants also discovered tubercle bacilli on his eye-glasses after a tuberculous patient had coughed. Hübner's tests are equally convincing. He took some bacilli prodigious in his mouth and established the fact that they were disseminated throughout the room as he spoke.—*Munich Med. Woch.*, November 15.

Spread of Throat Illness by Milk.—During 1897 there was at Surbiton a well-marked outbreak of follicular sore throat, and as the result of personal inquiry it was very soon found that a milk-supply was the apparent factor in distribution. A visit to the premises was made with no result, and a close inspection of the cowsheds and of the employees was also made. A sewer was being laid in the road outside the farm, and for a limited period there was a smell to be noticed; but it was unlikely that this could have so far affected the milk (since it was not kept stored on the premises near this road) as to render it in any way dangerous to health. A man whose business it was to milk the cows, was examined and found to be out of health, and suffering from well-marked tonsillitis and gastrodynia, and further with suppurating whitlows on the hands. He immediately discontinued any employment with the cows, and no further case occurred. There were considerably over thirty cases of illness, some very severe, under my notice, and probably many more.—*Public Health* (London), October.

Resolutions on Department of Health.—Dr. Liston H. Montgomery offered the following preamble and resolutions at a meeting of the Chicago Medical Society, Nov. 30, 1898, which were unanimously adopted:

WHEREAS, Legislation on the bill which was introduced in the United States Senate during the early period of the present year looking toward a Department of Health as a separate branch of our Federal Government was deferred, owing to the impending crisis of the Spanish-American War; and

WHEREAS, Said bill has the endorsement of the AMERICAN MEDICAL ASSOCIATION, the American Public Health Association and numerous State and municipal medical societies throughout the United States; and

WHEREAS, Much foreign territory to this country has recently been acquired wherein epidemic preventable and pestilential diseases have been and do prevail, and as many problems in sanitary science shall require careful study in these new fields; therefore, be it

Resolved, That for these, and for other obvious reasons, the Chicago Medical Society, through its officers, shall immediately request the President, in his forthcoming annual message to Congress, to recommend said contemplated Department of Health as an urgent necessity to our greater republic, and as a proper method for the protection to health and as a means of preventing a greater loss of life to American citizens visiting

these distant countries, and as a means of looking toward a higher civilization where disease and pestilence are sure to remain unchecked, and through the increase of traffic and commerce are liable to spread to our immediate shores unless some such humane measures are adopted;

Resolved, That a copy of this urgent appeal, namely, preamble and resolutions, be immediately transmitted to the President of the United States for the purposes herein explained, and to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for publication, with the request that they be published in medical journals elsewhere.

Typhoid Fever from Ice Cream.—The annual report of Health Officer Dr. Hops of Liverpool, records a prevalence of fever in a suburb of that city, known as the Knotty Ash district. Four cases were notified to this office about the same time, all being among young children attending the same school. Fifteen cases followed at short intervals, all from the same school. After careful inquiry possible sources of infection which may have existed at the homes of the patients were excluded, and it was ascertained that the milk supplied at the various houses came from dealers whose premises were in good order. Meantime, an investigation had also been made into the conditions of the school. Careful examination exempted the water-supply and the drainage of the school from suspicion. It was discovered that two or more children had been visiting at Knotty Ash early in September, and were suffering from typhoid fever at their own homes, and later on a pupil in a school at Denbigh was attacked under similar circumstances. None of these patients had been at the Knotty Ash school. Ultimately the total number of children infected with typhoid fever amounted to twenty-seven. Inquiry elicited the fact that a village fair had been held in Knotty Ash on September 6 and 7, and that every one of the children who had suffered from typhoid fever, including those who did not attend the school, as well as those who did, had been present at that fair, and all admitted, with two exceptions, that they had eaten ice cream sold by a vender at the fair, and the two exceptions were believed to have eaten chip potatoes purchased from the same vender, though one was too young and the other too ill to give a definite statement. The vender in question was reported to have come from Warrington; but after a careful search in the city, it was found that he was an Italian and had an ice cream factory in a low district of Liverpool, and there was, at the time of the fair, a case of typhoid fever in his house. It may be added that the following were the results of a bacteriologic examination of a sample of ice cream purchased of an itinerant Italian ice cream vender in London. It contained upward of 500,000 organisms per cubic centimeter. The bacteria isolated were the bacillus coli communis (the cream contained 200 or 300 per c.c.), streptococcus pyogenes, staphylococcus pyogenes aureus, staphylococcus albus, bacillus liquidus, bacillus liquefaciens, bacillus liquifaciens fluorescens, and bacillus ubiquitus. Neither oidium lactis nor bacillus diphtheriae was discovered.

Typewriting vs. Penmanship.—Dr. Bizzorero has discussed the advantages which typewriting possesses over the old-fashioned method of pen-writing. In his opinion penmanship is fraught with danger to the writer's health in a variety of ways. To begin with, the constrained attitude he is compelled to assume favors a distorted spine, and especially scoliosis, together with venous congestion, headache, epistaxis, dyspnea and congestion of the abdominal organs leading to constipation and dyspepsia, the latter disability being well-nigh inevitable should he sit down to write immediately after meals. The hands having to execute dissimilar work, the penman can not guide his pen without keeping his eye glued to its point, and so his vision is bound to suffer, asthenopia being a frequent sequela owing to the straining of the accommodatory apparatus. In the adults, vertigo and vomiting frequently complicate the case, but in children, whose power of accommodation is

greater, the complication to be feared is myopia. The use of a typewriter, according to Dr. Bizzorero, is a perfect remedy for all these evils, and for the following reason: The operator sits straight, with head erect and arms at liberty. His lungs have free play and his abdominal viscera remain uncompressed. His eyes undergo no strain, for he is not obliged to keep them fixed on a moving pen, in fact, after a little practice he can turn them away from the keys whenever he likes without interrupting his work. That distressing complaint, writer's cramp, so common among people who have to live by their pens, has no terrors for the typewriter. His occupation is an amusement to him, and without the least discomfort he can return to it after eating. But it is not to the healthy alone that typewriting presents so many advantages. Numbers of people who have the misfortune to be palsied can not use a pen, whereas they can express themselves freely, thanks to the machine; and many sufferers from conjunctivitis, iritis or choroiditis who have been forbidden to write after the old-fashioned style can in the same way carry on correspondence with their friends at a distance. If proof were wanting that typewriting has no injurious effect on the eyes it would be forthcoming in the fact that the blind readily become expert manipulators. Dr. Bizzorero advances rapidly in writing as a hygienic advantage, but the legitimacy of the claim is not very apparent. His contention in favor of legibility is, however, more likely to find acceptance, for in truth there are many handwritings of which the attempted deciphering can not but be highly injurious to the health of the unfortunate persons whose sad fate it is to endeavor to interpret the hieroglyphics. —London *Lancet*, October 29.

To the Physicians and Accoucheurs of Illinois.—The law creating a State Board of Health, emphatically declares that it shall be the duty of all physicians and accoucheurs practicing in the State of Illinois, to report all *births and deaths* which may come within their supervision; and where the reports are not made the county clerk may recover a fine of ten dollars. This law was enacted twenty years ago. At the same time there was one enacted regulating the practice of medicine, which declares, in substance, that no one shall practice medicine in any of its departments in the State, without giving sufficient evidence of at least a minimum qualification, which with other provisions, are designed to be executed and enforced by the State Board of Health. Such enforcement has driven thousands of quacks and nostrum vendors, charlatans and mountebanks from the State, and kept them out for the whole time. Thus, while it has been a great protection to the people of the State, it has afforded, incidentally, *privileges and immunities to you as physicians* of the whole State. You will please recall that these laws were enacted at the instance of the physicians of the State, by a legislative committee appointed at the May meeting of the Illinois State Medical Society, in 1876, and both laws went into effect the next year. The law was enacted very much as the profession, then represented, asked that it should be. In the meantime you have been quite anxious to have the quacks and nostrum vendors and others made to obey the law, while you have persistently neglected to obey the law yourselves in the matter of reporting births and deaths, so necessary to the collecting of vital, sanitary and mortuary statistics, and without good reason, while enjoying the *privileges and immunities* of the laws. Now, when the State Board of Health feels that it is time to make some advances in sanitation and further suppression of quackery, and to raise the standard of practice as a better protection to the people of the State, which incidentally will extend your *privileges and immunities*, we feel that in view of your past conduct we can not very hopefully ask the Governor and Legislature, which is clearly our privilege under the law, for the much-needed legislation to enable the Board so to do; when we will most likely hear the rejoinder, "how do you expect the legislature to empower the Board to make quacks obey the laws when the doctors themselves do not?" In view of these facts, I suspect that

you would better hunt up your old blanke and begin to practice reporting *births and deaths*; for while we shall ask for legislation along the lines suggested, we shall ask for that to enable us to enforce the collecting of vital and mortuary statistics as well. The blank forms in your hands and accessible to you are faulty, and some features of the reports required are burdensome, and you ought not to be made responsible for all the report requires; all of which will receive consideration at the next meeting of the Board, in January, but it is clearly your duty to comply with the law while you enjoy its privileges and immunities.—A. C. CORR, M.D., Pres. of Illinois State Board of Health.

Acute Epidemic Ophthalmia.—Hardly a year passes by, says Greeff, in the *Berlin klin. Woch.*, without an outbreak of acute Egyptian ophthalmia. No district is quite free, and each year acute ophthalmia makes its presence felt in or about Berlin. In the early Napoleonic time, Egyptian ophthalmia is said to have destroyed the sight of many hundreds in a few days. In pursuance of orders from the Government, Greeff has had good opportunity to study carefully true trachoma in regions where it is very common, and also one such epidemic in a district hitherto free. He discusses the features of certain epidemic ophthalmias which, though often confounded with trachoma or Egyptian ophthalmia, are really distinct. The mode of outbreak is not like that of trachoma, which does not spread so rapidly; trachoma is no doubt contagious, but every contagious ophthalmia is not trachoma. The contagious character of trachoma shows itself rather in the slow invasion of the other members of a family or household, of whom one or more has been affected for years, and this usually in a country or district where the disease has been endemic for a century, or it may be for ten centuries. He contrasts certain forms of conjunctivitis with one another and with trachoma. 1. In pneumococcus conjunctivitis, the pneumococcus (Frankel-Weichselbaum) occurs as an occasional inhabitant of the normal conjunctiva, and it may increase so as to bring about an epidemic. It is generally children it attacks; adults are but rarely affected. It is a transient malady, running a benign course somewhat quickly. 2. Morax and Axenfeld's diplobacillary conjunctivitis is a more chronic variety, in which the lids participate largely. In cover-glass preparations the germs are very numerous, lying for the most part in pairs, less frequently in chains. Implantation upon normal conjunctiva produces typical conjunctivitis. It is not certain that any epidemic of this has actually occurred. 3. The conjunctivitis of the Koch-Weeks bacillus seems to be the most frequent of the contagious conjunctivitis. When in Egypt, Koch found the germ in cases of the slightest form of so-called Egyptian ophthalmia. It is the cause of acute contagious conjunctivitis. It sets in very rapidly. Both eyes are usually affected; pain, lachrymation, photophobia, and a sense of burning are complained of. The inflammation lasts about two weeks, and the prognosis is uniformly good. As regards the bacterial origin of trachoma there is nothing settled; whether a diplobacillus or bacillus septatus is the cause is not certain. In case of an epidemic conjunctivitis arising, it is possible to make a diagnosis of its true nature by examination for micro-organisms. Sometimes it happens that the medical officer of a school makes the alarming discovery that a great number of the students are suffering from follicular enlargement, and he may find it necessary to close the institution. He must be careful not to be misled by an epidemic follicular catarrh, or, to be more accurate, follicular swelling. Schmidt-Rimpler, while engaged in the study of the cause of the frequency of short-sightedness in schools, noticed that many children suffered from some affection of the conjunctiva, and decided to make inquiries as to the frequency of catarrh, etc., at a time when there was no epidemic; he found a percentage of 31. On investigation Greeff finds follicles in 27 per cent. of the children. He believes them to be due not to contagion, but to a general pathologic condition; they are quite common in anemic girls whose conjunctivae are not in the least inflamed. Prolonged fomentation of the eye, as in the treatment of iritis, etc., will also produce them. The difference between them and trachoma granules is an essential difference.—*Edinburgh Med. Journal*.

BOOK NOTICES.

Repetitorium der Chemie. von Dr. CARL ARNOLD, Achte verbesserte und ergänzte Auflage, Verlag von Leopold Voss, 1898. Price 6 marks.

This work has been revised eight times in thirteen years, and, besides giving a good general review of chemic subjects, it treats of their special medical aspects and will make an excellent reference book for those who are able to read the German text. Particular attention is paid to the important combinations of the German pharmacopoeia for the benefit of the physician and pharmacist. The body of the work consists of a section of forty-eight pages devoted to the principles of chemistry; one of 228 pages on inorganic chemistry; one of 280 pages on organic chemistry; one devoted to revised nomenclature. A good table of contents and general index completes the volume, which is printed on good paper, has a flexible cover and is a recommendation for the publisher.

Pamphlets Received.

Advantages of Permanent Abdominal Anus, etc.; Advantages of Trendelenburg Posture; On Resection of the Gasserian Ganglion; Removal of an Angioma of the Liver by Elastic Constriction. By W. W. Keen, Philadelphia, Pa. Reprints.

Advertising in Some of Its Phases. By Frank A. Munsey, New York City. Paper, pp. 44.

Are Complete Castrates Capable of Procreation? By B. P. Sturgis, New York City. Reprinted from Med. News.

Auenbrugger and Laennec, the Discoverers of Percussion and Auscultation. By E. O. Otis, Boston, Mass. Reprinted from Boston Med. and Surg. Jour.

Belborough Trial, A Note on The. By Havelock Ellis. Paper, pp. 25. London: The University Press, 1898.

Ergot Aseptic; The Pharmacologic Assay of Heart Tonics. By E. M. Houghton, Detroit, Mich. Reprints.

Illinois Medical College, Fifth Annual Announcement. Chicago. Kentucky University Med. Dept., Announcement for 1899. Louisville.

On the Relationship of the Nose to Diseases of the Skin. By Walter A. Wells, Washington, D. C. Reprinted from N. Y. Med. Jour.

Satisfactory Method of Removing Powder Stains in Fresh Cases. By J. W. Heustis, Dubuque, Iowa. Reprinted from Ophthal. Record.

Some Advantageous Points in Operative Technic of Pelvic Surgery. By J. P. Crawford, Davenport, Iowa. Reprinted from Med. Record.

Vitality: An Appeal, an Apology and a Challenge. By Lionel S. Beale, London, England. Reprinted from the Lancet.

Trade Pamphlets.

The New 1898 Antitoxin Brochure of H. K. Mulford Company, a thorough revision and improvement of that issued last year, is a valuable reference book on the serum treatment of diphtheria. An interesting feature is a section of official reports on the employment of diphtheria antitoxin and a complete symposium of what all recent text-books say of the antitoxin treatment. It will be mailed gratis upon request.

Blennostasine. McKesson & Robbins, New York City.

Catalogue of Medical Publications. G. P. Putnam's Sons, New York City.

Columbia Desk-Pad Calendar for 1899. Pope Mfg. Co., Hartford, Conn.

Hemabolooids. Palisade Mfg. Co., Yonkers, N. Y.

Hygeia Hotel, The. J. G. Nichols, Citronelle, Ala.

Miscellaneous Pamphlets. Sehering & Glatz, New York City.

Munson's Typewriter Brochure. Chas. Ervin Hill, Chicago.

"One Food." John Cash & Sons, New York City.

Physician's and Surgeon's Pocket Dictionary of Medical Terms. Sent gratis on request. Katharmon Chemical Co., St. Louis, Mo.

SOCIETY NEWS.

San Francisco County Medical Society.—In the list of officers, recently elected (vide JOURNAL, November 26, p. 1305) by this Society, the president was erroneously given as Wm. H. Davis instead of George William Davis.

Otological Congress.—The Sixth International Otological Congress will be held in London, Aug. 8-12, 1899. Dr. Urban Pritchard, professor of otology at King's College, London, is president. The meetings will, by permission, be held at the Examination Hall of the Royal Colleges of Physicians and Surgeons, Victoria Embankment. The subject chosen for special discussion is "Indications for opening the Mastoid in Chronic Suppurative Otitis Media." The Congress, which assembles every four years, met last in Florence, where a very successful gathering was held under the presidency of Professor Grazi.

Chicago Medical Society.—A regular meeting was held Nov. 23, 1898, with Dr. Arthur D. Bevan in the chair. Dr. Truman W. Brophy spoke of the results of early operations for cleft palate, and exhibited three or four children upon whom he had operated. The results were excellent in all of them. Dr. Manning

presented a specimen from a case of osteomyelitis. Dr. Arthur R. Edwards reported a case of "Cystic Degeneration of the Kidneys," and exhibited specimens, and Dr. C. G. Buford also showed two kidneys from a case of cystic degeneration. Dr. H. T. Byford exhibited a fibroid tumor which had developed subperitoneally, and had attained a size sufficient to completely fill one-half the pelvis. He resorted to abdominal hysterectomy, and described the manner in which he removed the tumor.

Wayne County Medical Society.—The members, on December 1, visited the Ypsilanti Sanitarium, Ypsilanti, Mich. The distance from Detroit to the sanitarium is some thirty-one miles by street car line. Special cars were provided to convey the visiting physicians to and from Ypsilanti, and these were crowded to the doors with jolly doctors who had laid aside the arduous duties of their profession for a few hours to enjoy the outing. At the sanitarium a banquet was served and the visitors were afterward conducted through the institution. The Society then assembled in the large operating room of the building and was called to order by Dr. R. H. Honner, president. The following responded to toasts: Drs. C. C. Yemans, O. W. Owen, G. A. Kirker, James Hueston, J. J. Mulheron and J. Samson. Toasts to the secular press were responded to by Mr. Baker and others.

Washington Obstetrical and Gynecological Society.—At the 288th meeting of this society, held November 18, at the residence of Dr. W. P. Carr, Dr. G. Wythe Cook read the essay of the evening, reporting a case simulating peritonitis in a hysteric woman. The patient had been ill for several months, suffering from gastro-intestinal catarrh, and had traveled extensively throughout the country for health. Shortly after she developed marked symptoms of gastric ulcer, and during the attack developed symptoms simulating perforation and peritonitis. Dr. Van Rensselaer was called in consultation for the purpose of operating, but advised delay. The subjective symptoms became more marked, but were not in keeping with the temperature and pulse, which were practically normal. Eventually the case was considered hysteria and all the symptoms disappeared promptly under the administration of asafetida. An interesting discussion, with the citation of interesting cases, was participated in by Drs. Sprague, Van Rensselaer, Stone, H. L. E. Johnson and Bovee. Dr. H. L. E. Johnson presented a large polypus which he had removed from a female urethra. The growth was pedunculated, and grew from a point one fourth of an inch above the dilated meatus. The patient has been diabetic for several years and at one time was treated in a hospital at St. Louis. She had been passing large quantities of sugar, but that ingredient had promptly disappeared after treatment with iodid of potash. Dr. Stone presented a microscopic specimen of the cyst-wall from the specimen of supposed tubal gestation which he had exhibited at the previous meeting.

Philadelphia County Medical Society.—At the last meeting of the section on surgery of this society, Dr. Ernest Laplace presented a new pair of forceps he had recently devised for performing intestinal anastomosis. In order to prove its usefulness the speaker gave demonstrations on performing intestinal anastomosis with the instrument and proved that an end-to-end anastomosis could not only be more quickly and easily performed, but also that the lumen of the bowel was not lessened. The instrument may be roughly described as a double pair of forceps with long handles, but at an angle of about forty degrees and locked together. Instead of the blades being flat or grooved, each blade has a ring shape, so that the delicate tissues may be easily handled. The advantage of the forceps lies in the fact that one pair may be safely intrusted to an assistant while the operator is able to perform the operation with greater ease and rapidity. Dr. Laplace has given demonstrations upon the cadaver and also upon dogs, and in all instances the utility of the instrument has been proven. Drs. J. Chalmers DaCosta,

Edward Martin, Mordecai Price, Wm. L. Rodman and others, all spoke favorably of the instrument, and thought it possessed advantages over any other device or instrument for intestinal surgery. Dr. Edward Randall read a paper on "Catheterization of the Eustachian Tube" and took the position that the operation should be done more promptly by the general practitioner, who should become familiar with the method. As a medicament he thought the vapor of iodine the best. He preferred a catheter with a straight tip instead of the bulbous, on account of it being more readily introduced into the opening of the Eustachian tube. One of the speakers present dissented from the view taken by Dr. Randall, and preferred the tube with a rounded or bulbous extremity, because of less danger of doing harm in its insertion. The celebration of the semi-centennial of this society is to occur Jan. 16, 1899. A committee has been appointed to make fitting arrangements. Dr. J. Chalmers Da Costa will deliver an oration, and Dr. Kerr Boyce Tupper the memorial sermon. The committee having the matter in charge consists of Drs. William Welch, chairman; W. W. Keen, John B. Roberts, James Tyson, W. B. Atkinson, George M. Gould and A. H. Cleveland.

Detroit Academy of Medicine.—At the meeting held November 22, the Academy listened to a paper by Dr. Heneage Gibbs, health officer of Detroit, entitled "Sarcoma: Some Points in the Prevention of its Growth." He considers it essential to remember that while carcinoma is developed from normal tissue originating from the epiblast and hypoblast, sarcoma arises from tissues developed from the mesoblast, and is therefore of connective tissue type. Typical sarcoma consists of a mass of round and spindle-shaped cells with numerous blood-vessels running through the cells and lying in contact with them. Sarcoma grows from normal tissue which has reached the adult stage before the neoplasm begins to grow, but it first appears as embryonic connective tissue. Malignancy is associated with rapid growth, and the closer they remain to the embryonic type, the more malignant they are. Sarcoma, therefore, grows when presumably healthy tissue has been acted upon by some "influence" of which we know nothing, except that it has some connection with development. Classified according to the method of their growth malignant neoplasms may be divided into: epithelioma, glandular carcinoma and sarcoma. The first starts from squamous epithelium nourished in as normal a manner as any gland in the body. The third type is derived from tissue which is mechanical in function; but which under malignant influence grows and destroys everything on its way. It is nourished directly from the capillaries about the cells; it is therefore a neoplasm made of cells which by the rapidity of their formation promote the means for their destruction because of their low vitality. The cicatricial tissue formed about an old ulcer, while histologically presenting the same tissue as is formed in the early steps of sarcoma, differs essentially in not being under the malignant "influence." The method of prevention of growth in these neoplasms must, therefore, depend upon a study of the growth and development. Local treatment in the first class might stop their growth. In the second form both the circulation and lymphatics must be used and treatment must be local and general. The third form, especially when they approach a normal type of cell, is amenable to operation.

Detroit Medical and Library Association.—At the regular meeting November 21, Dr. E. S. Sherrill read a paper on "The Nature and Treatment of Accidents in Connection with Electricity." He divided accidents into two classes: 1, those arising from contact with an electric current, whether artificial or natural; 2, those from a remote effect not connected with actual contact. He said that death may be occasioned by actual lesion or destruction of tissue or by the arrest of respiration, producing asphyxia. He described the non-fatal cases

as those from which there is shock more or less severe with burning of tissue at the point of entrance and exit of the current. He summarized the effects of the electric current as: 1. In fatal lightning-stroke, punctate hemorrhages in various organs have been found and even meningeal and intrameningeal hemorrhage of considerable size. 2. In fatal shock from commercial currents few autopsies have been reported; the blood is usually found fluid and the viscera congested; small hemorrhages of the serous membranes are frequent. In both these classes there will usually be found the scarred tissue marking the point of contact. Non-fatal cases, he says, have burns of decided severity. There is a period of unconsciousness, usually followed by mental depression or excitement. The respiration is feeble, the pulse slow and small, the skin cool and the muscular strength lessens. Other symptoms may occur, such as loss of vision, nausea, diarrhea, etc. Such nervous symptoms as anesthesia, pain, hysteria, paresis, and even hemiplegia may occur. He gave the results of experiments on the effects of electricity which may produce death. It was reported at the Medical Congress at Rome that with a current of 1500 to 2000 volts the killing of animals was not sure and easy. It is believed that the more highly organized the animal is the greater the danger from an electric shock. Tesla has shown by a personal test that the alternating current of feeble ampèreage vibrating rapidly is harmless, even when the voltage is high, he himself having taken one half million volts. The arc lights of most cities are supplied by a current which has an ampèreage from 5 to 9 and voltage from 1000 to 2000. The treatment for accidents resulting from electricity should be: 1. Prophylactic. Those employed about electric machinery should wear suitable gloves. In some places employees wear a sort of harness which holds flexible strips of copper insulated and extending up the arms, over the shoulders and down the legs to the feet; in thunder-storms trees are to be avoided; in the house rooms containing stoves or open grates should also be avoided. 2. Medical and surgical. Artificial respiration should be thoroughly tried for at least one hour. The strong reflex influence caused by forcible stretching of the sphincter and muscle should be tried. Oxygen gas should be administered. When pain and nervous symptoms occur give hypodermic injections of morphine. Strychnia should be given for depression. Where there is slough from the burns they should be surgically treated.

At the regular meeting November 28, Dr. F. L. Newman read a paper on "Orbital Cellulitis," and gave the following reasons why this disease is of greatest interest to the general practitioner: He is the one most likely to see the case first; diagnosis usually presents great difficulty; the rarity of the disease; proximity of the tissues of the orbital cavity to the brain and the vascular connection with the other orbit. He gave as causes of orbital cellulitis, trauma, pyemia, facial erysipelas, facial boil or carbuncle, inflammation of the antrum of Highmore, phlebitis, purulent meningitis, typhoid fever, scarlet fever and diphtheria; it may also occur idiopathically in very delicate children. He gave as prominent symptoms of the disease, great swelling and redness of the upper lid; pain, increased on pressure; exophthalmus; congested and chemosed conjunctiva; high fever, etc. The disease should be differentiated from periostitis of the orbital wall and orbital growths. The diagnosis was minutely taken up. As an illustration he reported the following case occurring in his own practice: A girl 8 years of age had previously suffered from a sty on the eyelid. On the evening of January 20 she became very feverish and nervous and complained of a pain in the eye, the lid of which had commenced to swell. The Doctor found the child lying on her back with her eyes closed. The right eyelid was red and swollen, the pulse very rapid and temperature 105 degrees. She was extremely nervous. No exophthalmus was observed at this time. He gave

sedatives and an antipyretic. During the night the symptoms became so severe that another physician in the neighborhood was summoned, but Dr. Newman saw the child early next morning. The condition of the child was very much worse; both upper lids were enormously swollen and reddened and the child was now almost in the condition of coma. Another physician was called in consultation and it was decided that, on account of the meningeal involvement, the case was hopeless. The prognosis proved to be correct. The child began having convulsions very soon after and died at 5 o'clock on the 21st, having been ill less than twenty-four hours.

MISCELLANY.

Personal.—Dr. Sanger Brown has resigned from the faculty of Rush Medical College.

A Motto for the Antivaccin Party.—The philosopher, Hobbes, long ago declared that men would dispute the axioms of geometry when they had a strong interest in so doing.

"Philadelphia Medical Journal."—It is announced that, with the close of 1898, the *Philadelphia Polyclinic* will cease publication, subscribers receiving instead the *Philadelphia Medical Journal*. A similar arrangement was made with the *Atlantic Medical Weekly*, which ceased publication recently.

Inhalation of a Tooth Filling.—O'Donovan of Baltimore, in the *New York Medical Journal* of November 26, reports a case of bronchitis and pneumonia caused by inhalation of the filling from a tooth during extraction under nitrous oxid anesthesia.

Ethics of Homeopathy.—A medical gymnasium and bicycle club in St. Petersburg recently expelled a member on discovering that he was a homeopath, which fact he had concealed when applying for membership, but he declined to be expelled, and carried the matter into court, where it was decided in his favor. The club has appealed to the higher authorities.—*Deut. Med. Woch.*, November 10.

Artificial Thyrogenous Exophthalmic Goiter.—Notthafft reports the case of a man, 43 years old, who was ordered thyroid extract for obesity. Within five weeks he took nearly 1000 tablets, each containing 5 grains. For the first three weeks nothing was noticed, except loss of flesh, but after this time dyspnea came on, with swelling of the neck and very rapid loss of weight. Altogether, 30 pounds were lost, and five-sixths of this loss took place in the last three weeks. When examined, the patient had marked exophthalmos, with both Stellwag's and Graefe's signs; the thyroid gland was enlarged and pulsated, and there was a thrill over it; there was fine tremor of the fingers and tongue; the cardiac apex beat was displaced outward, and the pulse was 120 to the minute; there was cough and severe mental depression; polyuria and glycosuria also were present. Under the use of Fowler's solution and after the withdrawal of the thyroid extract, most of the symptoms rapidly disappeared, only the ocular manifestations and the goiter persisting for nearly six months. Notthafft considers the case one of thyrogenic Graves' disease, as the rheumatic pains and headache so common in thyroid poisoning were absent, and all the symptoms of exophthalmic goiter were present. He believes that Graves' disease may be due to qualitative changes in the thyroid secretion, and suggests that the explanation of the occasional good effect of thyroid gland extract in the affection may be attributed to the fact that the patient's thyroid is unable to produce a sufficient quantity of normal secretion, and, being constantly called upon to produce a secretion, gives forth one that is changed qualitatively, thus causing a poisoning that gives rise to the symptoms constituting Graves' disease. He believes, further, that the theories of a hematogenic or organic nervous origin of the disease are disposed of by the absence of any changes in the blood or

nervous system that are at all constant or could be considered sufficient explanation for the symptoms. The theory of a pure neurosis, based upon the occasional hereditary transmission of the disease, or its association with other neuroses, and similar arguments is, he believes, after a careful study of the literature, not justified, as such occurrences are probably coincidences. The theory placing its causation in some changes in the thyroid gland is fully justified by the almost constant presence of changes in this gland, both clinically and pathologically by the frequent association of exophthalmic goiter with myxedema, which disease is indubitably connected with the thyroid gland, and by the frequent improvement in cases of Graves' disease after operations upon the thyroid gland. An extensive reference to literature accompanies the article.—*Centralblat. für innere Medicin*, April 9.

Gastric Tetanus.—Sievers describes two observations of fatal tetanus complicating gastric dilatation from small cicatrized ulcers. There are twenty-seven cases of the kind on record, the dilatation usually caused by the cicatrization of an ulcer, and consequently accompanied by "hyperchlorhydrie," but in a few cases there was neither dilatation nor "hyperchlorhydrie," as in Blaziesek's case, in which the distended gall-bladder compressed the duodenum. In three cases the ulcer was complicated with carcinoma.—*Rev. Gen. de Path. Int.*, November 5.

Acute Delirium from Auto-Intestinal Intoxication.—Soelder relates observations of six cases, all young women or girls, in otherwise good health, suddenly affected with motor excitement, distress, cephalgia, uninterrupted walking, death following in a week or two from cardiac paresis. The anatomic changes were cerebral hyperemia and edema, intense congestion of the lungs, parenchymatous degeneration of the kidney, heart and liver, and chief in importance, a coprostasis of the large intestine, although there were no indications of digestive disturbances and no signs of increased putrefaction of the albuminoids in the urine. Similar cases have been attributed to the cerebral hyperemia or to a bacterial invasion of the brain, but the toxic lesions of the large organs favor his theory of an intestinal auto-intoxication.—*Rev. Gen. de Path. Int.*, November 5.

Cocain Poisoning.—A considerable proportion of the fatal cases after the use of cocain has been among medical men who have treated themselves for purposes of relieving pain, and have by accident or design injected an overdose. An instance of this kind occurred a few years ago. The body of a young medical man was found at a railway station. In his hand was a hypodermic syringe containing morphia which he had evidently been about to inject as an antidote. He had been accustomed for some time to inject cocain for the relief of neuralgia. On April 13, Dr. Thomas held an inquest at Paddington on the body of the wife of a medical man, who had died after drinking a solution of cocain. Eight weeks previously she had swallowed a quantity of laudanum from a phial which she had found in her husband's bag, assigning no reason for doing so, but telling him immediately after the act. Antidotes were applied and she recovered. On the evening of April 13, she remarked to her husband, "I am feeling ill," and produced a small bottle from her pocket containing a solution of cocain, which she had abstracted from the bag when she had obtained the laudanum previously. Both bottles were duly labeled "poison." She said she had taken cocain and asked that a medical man be sent for, but all treatment was unavailing. All experience shows that care is requisite in administering cocain, as it has again and again happened that small amounts of the alkaloid have given rise to the most threatening symptoms. Two-thirds of a grain injected subcutaneously caused the death of a woman aged 71 years, in five hours, and a man died almost immediately after taking twenty-two grains by the mouth. Persons, however, habituated to its use can take increasingly

larger doses. Among the most striking illustrations of its threatening characteristics are abnormal exaltations of the feelings, loquacity accompanied by mental incoherence, severe sweating, fall of temperature, shallow and irregular respiration, dilation of the pupils, disturbance of vision, nausea, feeble pulse and, ultimately, collapse. In persons suffering from these symptoms stimulants should be given. The inhalation of chloroform has been tried to relieve the spasm. Nitrate of amyl has also been suggested. Some medical men make it a practice to give a preliminary hypodermic dose of from one-eighth to one-quarter of morphia, according to the age of the patient. The physiologic antagonism between the drugs is pronounced, so that while morphia is not an absolute antidote, it is at least most valuable in counteracting the toxicity of cocain. Dr. Griffin, in the *Philadelphia Medical Journal*, has pointed out the variety of susceptibility and idiosyncrasy to cocain which different individuals present. Some patients who are acutely poisoned exhibit maniac excitement, while others are stupid. It is well known that poisoning has followed the use of a dose far short of the maximum therapeutic allowance, even a fraction of a grain having been reported to have caused serious symptoms. There are also instances in which a solution of a certain strength has been used without unpleasant effects, while a repetition of the same dose on a subsequent occasion has caused toxic symptoms. The injection of camphor dissolved in ether and the employment of artificial respiration, have recently been extolled as the best treatment for the acute poisoning. In chronic poisoning by cocain there is one symptom, known as Magnan's sign, which is of considerable importance in establishing a diagnosis when the use of the drug is denied, and is also of importance in other cases as indicating to the physician the necessity for immediate discontinuance of the remedy. This sign is an hallucination of sensation, the patient complaining of feeling some foreign body beneath the skin. This is generally described as being small in size, and is usually ascribed by the patient to the presence of sand, worms or microbes.

Artificial Immunity and Cure of Infective Diseases.—R. Emmerich and O. Löw publish a preliminary communication in the *Munich Med. Woch.* of November 8, in which they assert that the final destruction of bacilli is due to an enzyme which they themselves form, the effects of which are transferable from one kind of bacillus to another. They state: 1. The growth gradually ceases in many cultures, in spite of an abundance of suitable nutrient medium, and this they have found to result from the presence of an enzyme, formed by the bacteria, which in time destroys them. 2. Some of these bacteriologic enzymes are able to destroy other bacteria, even the pathogenic, besides the species from which they were derived. As these bacteriolytic enzymes are also able to destroy pathogenic bacteria in the animal organism they are capable of curing infective diseases. It is an easy and certain process to cure, with the enzyme of the bacillus pyocyaneus, within thirty hours, an anthrax infection progressing to a fatal course. 1 c.c. of this enzyme solution dissolves *in vitro* in twelve to twenty-four hours millions of diphtheria, cholera and typhus bacilli, showing that this pyocyaneus enzyme can also be used for these infections. Even the plague bacillus is destroyed by it. 1 c.c. will dissolve thirty millions of plague bacilli within a few hours. 4. The bacteriolytic enzymes are destroyed in the animal organism and permanent immunity can not be obtained with them, although a few injections will cure the infective disease. But the writers have succeeded in combining the enzyme *in vitro* with an animal albuminoid which makes it last longer in the animal organism and therefore adapts it to immunization. With this highly molecular complex combination they have succeeded in immunizing rabbits against

anthrax and guinea pigs against diphtheria. In all probability the effective principle of an immunizing serum is nothing but a combination of the specific enzyme with an organic albuminoid (cause of artificial immunity). The so-called "agglutination" is the first stage in the dissolving of the bacteria by the enzyme combination. 5. The difference in the behavior of the immunizing sera in the presence of specific, pathogenic bacteria *in vitro* and in the animal organism, depends upon the presence or absence of oxygen in the form of gas. Excluding this completely, *in vitro*, the specific pathogenic bacteria are not only agglutinated by the immunizing serum but killed and dissolved, as was proved repeatedly with cholera and typhus bacilli.

Peptones in the Organism.—A communication received by the Académie de Méd. states that the assumption that peptones are toxic products is due to the impurities they contain, which are easily removed by Gautier's new process. The writer proves their non-toxicity by his experiences with animals, to which he administered peptones by both the gastric and intravenous route, finding that the animals gained rapidly in weight, thus also establishing their great nutritive value. Animals fed with peptones combined with carbohydrates, fats and mineral substances, thrived far better than others without the peptones. They do not produce incoagulability of the blood; they merely seem to augment the vitality and the number of the corpuscles. They can not be used for therapeutic anti-infectious purposes, in intravenous injections, for example, as the peptonized animals succumbed more rapidly than the control animals. Their use is indicated, however, whenever gastric nutrition with the usual nitrogenous foods is defective. In such cases the ingestion of peptones by the stomach or rectum offers unquestionable advantages. He also establishes the fact that while plants and microbes manufacture peptones and other albuminoid substances from relatively the simplest nitrogenous elements, the animal, on the other hand, does not manufacture albuminoids even from the most complex nitrogenous products. For the animal, therefore, there is nothing that can take the place of the albuminoids.—*Bulletin*, October 31.

Governmental Meat Inspection.—A case is instanced in the *Northwestern Reporter* to show the marked differences that exist between the law as laid down in England and the law as declared in this country in relation to the implied warranty of wholesomeness upon the sale of meat for immediate domestic use. The plaintiff was a woman who bought some pork from the defendant, a retail dealer in meats, who knew that she purchased the pork for immediate consumption by herself and family. The pork was, in fact, unfit to eat, and made the plaintiff and her family ill. She sued for breach of the implied warranty of wholesomeness. The trial court held that there was no such warranty, and the defendant had judgment there; but the supreme court reversed it, saying in the course of the opinion: "In England at common law there could be no recovery, as there was no implied warranty or quality. But the law on the subject as established in England does not prevail here. As a rule, we think the decided weight of authority in the United States is that on all sales of meats or provisions for immediate domestic use by a retail dealer, there is an implied warranty of soundness or wholesomeness." The system of meat inspection by officers of the National Government has been pronounced unconstitutional in the decision rendered by Judge John Rodgers in the United States District Court for the Western District of Arkansas. He set aside an indictment for bribing a Government meat inspector, on the broad ground that the Federal Constitution does not confer upon Congress any power to legislate in reference to the packing of meat in storehouses or the inspection of meat when thus stored. Hence he holds that the attempt to establish the office of meat inspection

tion was ineffectual, and there is no such officer. Notwithstanding this decision, it is announced from Washington that meat inspection will be continued for the present under the direction of the Department of Agriculture. The new attorney-general thinks that the indictment passed on by Judge Rodgers omitted to state facts which would have shown that the inspected meat was really in transit from one State to market in another, and thus became liable to Congressional legislation as a subject of interstate commerce.

The Roentgen Ray in Tuberculosis.—R. Mühsam reports tests with radiotherapy on twenty six guinea pigs, successful in arresting local tuberculous processes, though general infection was not affected by it (*Deutsche Med. Woch.*, November 10). Ausset and Bedart describe a case of chronic tuberculous peritonitis in a girl of 9 years rebellious to all therapeutic measures, cured completely with radiotherapy when the prognosis seemed very unfavorable. There were fifty sances in all, averaging thirty minutes, the tube 12 cm. from the skin. —*Echo Med. du Nord.*, November 13.

Common-Sense Infant-Feeding.—In the *Medical Record* of November 26, Fischer of New York presents several formulæ to be followed when nature has been unkind and deprived the infant of its proper food—breast milk. For an infant under two months old, to be nursed or fed not oftener than once in two hours from 6 A.M. to 10 P.M. (some requiring an extra feeding at 2 A.M.), he orders the following mixture: Cow's milk 200 gm., water 700 gm., milk sugar 30 gm., to be divided into eight parts, the quantity for each feeding consisting of about 100 gm., or 3 oz. For a child from two to four months old, he orders a mixture of: cow's milk 350 gm., water 700 gm., milk sugar 36 gm., to be divided into seven parts of 150 gm., or 5 oz., and feeding to be not oftener than every two and one-half hours. Formula No. 3, for a child from four to five months old, contains: cow's milk 500 gm., water 500 gm., milk sugar 40 gm. This mixture is to be divided into six portions, e. g., three bottles containing 6 oz. and three containing 5 oz. each, the 5 oz. bottle alternating with the 6 oz. bottle every three hours. The child from five to nine months old is to be fed every three hours, the following mixture being divided into three 6-oz. and three 7-oz. portions, and given alternately: Cow's milk 750 gm., water 375 gm., milk sugar 50 gm. Formula No. 5, for children from nine to twelve months old, comprises: Cow's milk 1125 gm., water 375 gm., milk sugar 50 gm. This mixture is divided into eight portions, 8 oz. each, and one bottle given every four hours. Over one year of age, he uses pure cow's milk undiluted, feeding 8 oz. every four hours, the formula being: Cow's milk 1500 gm., milk sugar 59 gm., this quantity being divided into six portions, each containing 8 oz. He emphasizes the necessity of sterilization of everything used in connection with infant-feeding, e. g., cow, pail, stable, etc., also the importance of boiling the nipples immediately after being used, in plain water to which a pinch of salt has been added. They should then soak in salt water until to be again used. If a child takes only half a bottle's contents, the remainder must be thrown away and a fresh bottle be used. He also emphasizes the individualization of feeding, some children requiring food once in three, others every hour. He weighs the child weekly, and if there is not an increase of four to eight ounces during the first three or four months of infant-feeding and several ounces weekly, up to dentition, it is safe to change the method of feeding.

Operating on Wrong Leg.—As the basis of an action for damages sought to be recovered from a practicing physician and surgeon, it was alleged that he was employed to operate upon the plaintiff's right leg, but after putting the plaintiff under the influence of chloroform, wrongfully and carelessly operated upon the left leg, thereby causing the plaintiff great pain and suffering. According to the plaintiff's testimony his right leg was

very sore, and from time to time he got medicine from the defendant, until the latter finally advised him to go to the hospital, and on the following morning the nurse prepared him for the operation by shaving the right leg from the knee down, as the operation was to be upon the shin bone, some wash also being put on and the leg bandaged. He was then taken to the operating-room and given chloroform. On cross-examination he acknowledged that the left leg had also at one time troubled him, but maintained that it had healed. The nurse testified that the patient had a swelling on both legs, but prepared the right one, which was a little discolored, for the operation on being told by the patient that was the one. The plaintiff's brother testified that when the plaintiff was on the operating-table and both legs were exposed, the defendant said: "See here! you fellows have made a mistake; you have prepared the wrong leg for operation." But when the defendant asked this brother which leg it was that the plaintiff wanted operated upon he could not tell, stating that he was confused, but would telephone his folks and make sure, which was assented to but not waited for, perhaps because at about that time the father of the plaintiff appeared on the scene, though previously told by the plaintiff not to do it, and when asked if it was the right leg, which was pointed out, said "No, the other leg," though he said he had his mind on that leg all the time, and thought that the defendant could not make a mistake. Thus, according to these witnesses, did the left leg come to be operated upon; and a week or so afterward the defendant operated on the right one. The case was tried before a jury, and the court directed a verdict in favor of the defendant. But the supreme court of Michigan holds, *Sullivan vs. McGraw*, that the case should have been submitted to the jury for their determination, whether the defendant exercised that degree of care which, under the circumstances, he was bound to exercise, the supreme court considering that there was evidence tending to prove negligence, wherefore it reverses the judgment of the lower court and grants a new trial.

Experimental Surgery of the Heart.—Some extensive experiments are reported from Breslau, in which the hearts of rabbits and dogs were subjected to all kinds of wounds, punctures, incisions, etc., and then sutured, with the result that it is apparent that the heart of the mammal, of the rabbit at least, can stand even quite large wounds if excessive hemorrhage is prevented. The application of a suture even nearly around the heart does not, per se, determine any serious effect if secondary injuries are avoided. It was found that the third, almost the half, of the ventricle could be excised without injury after applying a tobacco pouch suture or ligature above. Several animals were operated by applying a ligature around the ventricle just below the middle, and the heart was then pierced entirely through with a small scalpel just below the ligature, that is, through the wall of the left ventricle, the septum ventriculorum and the wall of the right ventricle. The blade was then drawn downward, dividing the lower portion of the heart into two pieces, opening both ventricles. The wound was then sutured and the ligature removed. One died from the slipping of the ligature; another from sepsis. The other four are alive and well to date (three to five weeks). The danger of hemorrhage is much greater after wounds of the right ventricle than of the left. The sutures included only the pericardium and the upper muscular layers. They must be tied during diastole, as otherwise they tear out. The effect of the operation on the action of the heart was first a slight delay in the next systole, then an arrhythmia lasting several minutes. If the heart wall is punctured or incised very slowly and carefully through the different layers it will be observed that the arrhythmia only appears during the injury to the pericardium and the endocardium. While the needle is passing through the heart musculature the organ beats with normal regularity.—*Cbl. f. Chér.*, October 28.

Rehabilitation of Severed Parts.—A writer in the London *Lancet*, October 22, refers to certain recently reported cases in that journal, showing the possibility of the restoration of severed parts of the body, even under very unfavorable circumstances. He refers to three cases in which the severed external ear was successfully replaced. In one the circumstances were anything but encouraging. The ear had been bitten off by a horse and was found lying in a stable-yard. Neither surgical instruments nor antiseptics were available, and a common needle and thread had to be used. In the other two cases the surgeon adopted the ingenious plan of keeping the ear warm and endeavoring to restore the circulation by hot salt bags. We do not know of any other instances in the attempt to restore severed parts in which this had been done. To what extent it is useful it is difficult to say; at any rate it is rational. Several cases of union of severed finger-tips are recorded. In the *Johns Hopkins' Bulletin* (November, 1892), Dr. Finney published a case of surgical suture of severed finger-tips after seven hours. The middle finger was cut off just below the last joint through the phalanx, the ring finger at the root of the nail. The raw surfaces were freshened and the tips were attached each by four sutures. Dr. Finney used antiseptic dressings, but not solutions, because bichlorid of mercury and carbolic acid produce a thin layer of coagulation necrosis. The wounds united by first intention. In a recent number of the *New York Medical Journal* appears an account of an interesting cure that occurred in the practice of Dr. Laurens. A colored man, in using a heavy axe, cut through his shoe and severed the metatarsal bone of the first toe through the head, completely disarticulating the toe, and also cut off the second toe in front of the metatarsal joint. He was seen four hours afterward. The shoe and sock were cut away and the second toe found separated, while the first was hanging by a mere string of skin, every muscle and vessel being cut. They were united by interrupted sutures which included the tendons. A dressing of iodoform and boric acid, equal parts, was used and a spint was applied. The iodoform had to be discontinued before it proved irritating. Union by first intention occurred over more than half the wound and there was but little pus when granulation took place. On the third day sensibility was present in both toes, and in a week the patient could move them a little. Finally, they were strong, movable and sensible, and except for a little tenderness the foot was as good as ever.

Brachialgia and Brachial Neuralgia.—After eliminating the cases of brachialgia due to rheumatism, myositis, inflammation of the synovial sheaths, an affection of the bones or joints, or to peripheral traumatism. Oppenheim has still 189 cases to consider. In 15 there was a vertebral or medullary affection (caries, tumor, tabes, glioma), with pain in a single arm. In 30 cases there was an evident neuritis, with paralysis and anesthesia, either of an infective or toxic nature; in 6 cases it was consecutive to influenza. Others were caused by the pressure of a tumor (aneurysm of the subclavicular, sarcoma). In 12 cases it was impossible to distinguish between neuralgia, neuritis, myalgia or some other lesion, and in 22 cases there was neuralgia without a neuritis or lesion of the central nervous system, evidently due to diabetes, gout, alcoholism or an acute affection. In 14 cases the pain was only induced by an effort. In the principal group, including 96 cases, there was brachialgia proper, with no points distinctly painful to pressure, but rather a psychalgia, consecutive to hysteria, neurasthenia, hypochondria, melancholia. The cases were chiefly in men, and the pain varied with the psychic condition. In some cases the brachialgia was associated with scoliosis. These brachialgias had developed after a traumatism. In some cases they could be attributed to masturbation, more often to rebellious insomnia. The pain in these cases yields to suggestion. In one patient who had in vain tried nearly every kind of treatment,

it yielded to a single injection of antipyrin. Several cases relapsed or resisted all therapeutics. Brachialgia should be carefully differentiated from brachial neuralgia.—*Rev. Gen. de Path. Int.*, November 5.

Ovaries and Marriage.—The position taken by Mr. Justice Hirschberg, in the case of *Wendel vs. Wendel*, as stated in the *JOURNAL* of September 17 (page 676), does not meet with approval by the second appellate division of the supreme court of New York. The latter, referring to the decision below, says that it was held that because of the loss of her ovaries the defendant was incapable of conception, and, therefore, of "entering into the marriage state;" and that while this conclusion is in harmony with those higher ideals of the marriage state, which ought not to be disturbed except upon grave considerations of public policy, it is forced to conclude that the effect of such a rule was not fully considered. It goes on to state that it is a fact well known to medical science, and familiar in our common experience, that every woman passes through a climacteric period, usually between the ages of 40 and 50 years, after which she is incapable of conception, and yet it has never been suggested that a woman who has undergone this experience is incapable of entering the marriage state, or that she is guilty of any fraud in contracting marriage. In this latter case the ovaries are shrunk and contracted to a point where they no longer discharge the functions necessary for conception, and in so far as the reproduction of the species is concerned, the one is as incapable of "entering into the marriage state" as the other. There is no essential difference between a woman who, through no fault of her own, has lost her ovaries through a surgical operation, and one who has suffered the same result through the operation of nature, and if the one is incapable of entering into the marriage state, the court can conceive of no process of reasoning by which the other may be said to be capable. It seems to it clear, therefore, that it can not be held, as a matter of law, that the possession of the organs necessary to conception are essential to entrance to the marriage state, so long as there is no impediment to the indulgence of the passions incident to this state. Consequently, it reverses the judgment of the lower court. And as to the contention that the defendant was guilty of fraud in not pointing out her exact condition upon being questioned by the plaintiff, the court suggests that he had not availed himself of the means of information within his reach and suggested by what the plaintiff had told him, and, it holds, that cohabitation for a time after learning the facts constituting the alleged fraud must deprive him of the right to have the marriage annulled on that ground.

Depositions Taken Before Trial.—What it thinks was a novel as well as an exceedingly interesting question was presented to the fourth appellate division of the supreme court of New York, in the recent personal injury case of *Ida Green vs. the Middlesex Valley Railroad Company*. It seems that at the instance of defendant the plaintiff was, prior to the trial, required to submit to a physical examination, as provided by section 873 of the New York Code of Civil Procedure. This examination was made before a referee, and in the presence of two female physicians, who gave oral evidence before the same referee, and their depositions thus taken were offered in evidence upon the trial. In each instance the offer was objected to upon the ground that the depositions could not be read in evidence, save in the absence of the witness, and that the witnesses were then present in court under subpoena. The trial court overruled the objections and permitted the depositions to be read, which ruling was duly excepted to, raising the question referred to. The section of the code mentioned, the appellate division says, is part of a general scheme provided by the legislature for the examination of parties before trial, and, as amended in 1893, it was obviously intended to establish a rule

of procedure by which, in cases of this character, a defendant could ascertain the nature and extent of the personal injuries from which the plaintiff claimed to be suffering, and thereby enter upon the trial of his case with some knowledge of what he would be called upon to meet. The method by which information was to be obtained was not clearly defined by the statute, but it seems to be now settled that the physical examination which it contemplates is but a part of the examination of the party before trial, and that it is to be conducted by the oral examination of the plaintiff, as well as of the attending physicians. But, when this much has been accomplished, the question naturally arises as to how far, and under what circumstances, the depositions thus taken are competent evidence upon the trial. The view of the trial court, as applying to this case, has been referred to. But the appellate division does not concur therein, although it has been judicially stated that the record of the examination, which is placed on file, may be introduced in evidence, and section 881 provides that the deposition, or a certified copy thereof, may be read in evidence by either party at the trial. In section 882, it finds a limitation, which leads it to hold that it is not until a party has shown his inability to produce the witness upon the trial, in order that the jury may have the benefit of an examination of the latter conducted in open court, that he will be permitted to read his deposition, and that therefore the defendant in this case had a right to insist that the attending physicians should be required to give their evidence in the same manner as would have been the case had their depositions been taken separate and apart from the plaintiff's physical examination.

Christian Science.—The *Chicago Standard* has entered a protest against a continuation of the immunity from prosecution for their crimes which the "Christian Scientists," thanks to a general misunderstanding and misapprehension of the phrase "religious freedom," now enjoy and abuse in this and many other countries. The idea that any unfortunate victim of mental and physical lesions, or any shrewd and conscienceless exploiter of human credulity, can defy the law and practice the rites of any cult, no matter how degrading, vicious or dangerous, provided the dupe or the knave takes the precaution to call the cult a "religion," is, of course, a wild absurdity, a delusion, which has no basis in reason or the statute books. "The law," declares *The Standard* with perfect accuracy, "can not interfere with religious opinions unless they lead to infractions of well-known principles of morality and public policy; but in such cases it should act promptly. Mormonism encounters the law when it leads to polygamy. 'Christian Science' should feel the law's restraint when it leads to suicide and manslaughter." That it does both in many instances, is known to everybody who has paid even slight attention to this monstrous and horrible fraud. The case of Harold Frederic is at once maddening and pathetic. All his years the man had lived and fought for the realities, the sanities, and the honesties of life. Finally a cell or a duct in the overworked brain gave way and left him temporarily and partially incapable of distinguishing between the true and the false. Nature, aided by science, would have soon repaired the injury, but at the moment when the clear eyes were darkened and the strong mind was helpless, a miserable creature appeared, stretching out rapacious hands for the sick man's gold. She got it, and Harold Frederic is dead. There is ground for hope, however, that this is not quite the end of the tragic episode. The woman who killed Mr. Frederic has confessed her utter lack of legal qualifications to act as a doctor, and that she accepted fees for treatment. Counsel for the executors warned her, while she was testifying before the coroner's jury, that she was in a "serious position." If England has any justice, she will soon be in a prison, and stay there for a very considerable period. Would that every one of her rivals might bear her company.

The High-Grade Modern Hospital.—Dr. Stephen Smith writes of the new era of hospitals and dispensaries. They are no longer regarded as for the sick poor alone, or for the stranger within our gates alone, but for any sick person, be he poor or rich, old or young, whose malady falls within the range of a large class of diseases. During the first half of the present century the State of New York had but one well organized hospital; the century will close with not far from two hundred such institutions, upward of ninety of which are located within the limits of the Greater New York. The modern hospital is constructed on the segregate plan, which so isolates the various parts and rooms that ventilation of one room into another is, as far as practicable, prevented. The modern operating-room is located, constructed, and managed so as to secure the most perfect purity of the air and the most absolute cleanliness. Skilled service is everywhere required. The resident medical staff is selected after competitive examination; the apothecary is a graduate of a college of pharmacy; the head of the kitchen is a *chef*; the matron is a trained nurse. But perhaps the reform in hospital management which has wrought the most salutary results is found in the department of nursing. Today the nurse of the most ordinary hospital is a person of good education, of the most pronounced correct habits, familiar with the import of those symptoms of those diseases that indicate an emergency, reliable in the use of remedies, and skilled in all the arts of relieving the sick by manipulation. In view of the imperious demands of modern medicine for the best possible hygienic conditions surrounding the patient, for perfect antisepsis in all surgical operations, for the greatest precision in all the details of nursing, it is very gratifying to be able to record the fact that the public is responding cheerfully and generously to these requirements upon it for financial resources. Hospitals of the highest type of excellence are appearing in every community, not only for general disease, but for every variety of human affections which can by any means be better treated in hospitals than at home.—*Charities Review*, November.

State Care of the Insane in Indiana.—The State of Indiana needs more room in her hospitals for the insane; they are not quite big enough and never have been, notwithstanding the expenditure within fifty years of \$3,000,000 on their development, and a present capacity for 3300 inmates. The population of the State now amounts to 2,900,000, the number of insane is 4200. Nothing seems to be more disquieting to the average citizen than a call for increase of hospital capacity for the insane. Forthwith it is assumed that mental disease, if not epidemic, is certainly spreading. Commonwealth and citizens should remember that change makes change; that as population thickens the defective element at least maintains its ratio if it does not exceed it; that a ratio must be met, rather than a fixed number, and that the hospitals for the insane should have always a bed ready beforehand for the unfortunate one out of 400 or 600, as the case may be. In every community this is a permanently increasing demand. The prompt and proper care of the insane can only be cured by a wise, liberal and timely adoption of the above policy. This is the humane way of looking at the question: Prevision is needed as well as adequate provision.—Dr. J. G. Rogers, in the *Charities Review*, November.

The Drug Trade in Europe.—An interesting volume of 417 pages has been issued by the Bureau of Foreign Commerce of the United States Department of State, which is a mine of information regarding the conditions of the drug trade in foreign countries. The sponsor of this collection of consular reports, Mr. Joseph Jacobs, a pharmacist of Atlanta and chairman of an important committee in the American Pharmaceutical Association, requested the Department of State to submit a series of questions relating to drugs, chemicals, proprietary articles,

drug stores, pharmacies, laws governing the practice of pharmacy, etc., to the consular officers of the United States in foreign countries. The responses constitute a volume of great interest and value, which will undoubtedly receive much notice, here and abroad, and will serve as a record basis for a long time to come. In Austria, for instance (and in Germany the conditions are very similar), "the law distinguishes between a druggist and a pharmacist, and draws a line between the two which neither is permitted to overstep." The druggist conducts a shop something on the plan of the average drug store here; but the pharmacist requires a university diploma, and can conduct a pharmacy only if he acquires a "concession." The concessions are limited, and attach to a location or are hereditary; a new concession is granted only on the basis of a location distant at least nine and a half miles from the nearest similar establishment, and provided a population of 4000 or more people is tributary to it. This is fine protection for the owner of a concession. In Germany no person can practice pharmacy until he has passed his "state examination"; a foreigner, with a foreign diploma, must pass this examination (requiring academic accomplishments) before he can even become an assistant in a pharmacy. The native candidate, having passed through high school and with a thorough knowledge of Latin, serves three years as apprentice; then three years as assistant in an authorized pharmacy; then three semesters devoted to theoretic study in a German university; and then he is qualified to attempt the final state examination. There is some difference, evidently, between an average "drug clerk" and a German *apotheker* who has passed the examination.—*American Therapist*, October.

Gleanings.—Impermeable stricture of the esophagus consecutive to swallowing "caustic soda," cured by retrograde sounding through a gastrostomy incision (*Munich Med. Woch.*, November 15.)—Fatal case of rupture of the spleen in typhoid fever. Weighed 600 grams. (*Tidsskrift f. d Norske Laeg.*, November 1.)—Carcinoma of the right suprarenal with metastases in the liver, lungs, etc.; and the rare picture of a metastatic carcinomatous hemorrhagic fibrinous pericarditis.—Case of rupture of the uterus, related by Heissler in which the ruptured ring-shaped lower segment of the uterus was expelled. (*Munich Med. Woch.*, November 15.)—Bruns reports 81 subperiosteal amputations of the leg with extremely favorable functional results and gangrene of the flap in only three cases. (*Beiträge z. Klin. Chir.*, xxii, 2.)—Vienna has no crematory, and consequently the request of Dr. Müller, the devoted victim of the recent plague epidemic there, that his body be cremated to avoid further infection, was necessarily disregarded, as transportation to a distant crematory was out of the question.—Cystoma removed from a woman of 38 years, containing thirty-four liters of fluid. The circumference of the abdomen at the level of the umbilicus was 152 c. Prompt recovery. (*Revista de Med. y de Cir.*, October 25.)—One or two drops of bile introduced under the dura in rabbits through a trephining opening, produce symptoms of severe intoxication; the animals run around and when they fall from exhaustion continue the motions of running. (*Klin. Woch.*, November 13.)—Chronic constipation cured with massage of the hepatic region, especially of the gall-bladder. (*Gaz. Méd Liège*, November 10.)

Societies.

The following recent meetings are noted:

Illinois.—Rock River Medical Association, Sterling, November 22; Will County Medical Society, Joliet, November 22.

Indian Territory.—Indian Territory Medical Association, Wagner, December 6 and 7.

Michigan.—Saginaw County Medical Society, Saginaw, November 25.

Minnesota.—Ramsey County Medical Society, St. Paul, November 28.

Missouri.—Medical Society of City Hospital Alumni, St. Louis, December 1.

New York.—Medico-Chirurgical Society of Central New York, Syracuse, December 1.

Pennsylvania.—Clinton County Medical Society, Lock Haven, November 18.

Texas.—South Texas Medical Association, Houston, December 8.

Detroit.

APPOINTMENTS.—Drs. W. R. Henderson and G. P. Johnson of Detroit have been appointed by the Wayne County auditors to act as county physicians for the ensuing year.

HEALTH REPORT.—For the week ending December 3, there were: Deaths 76, under 5 years 18. Births, female 18, male 34. Contagious diseases: Diphtheria, 20, recovered 9; new cases 14, 2 dead; 23 now sick; scarlet fever 29, recovered 6, new cases 14, 37 now sick; smallpox 1.

Louisville.

DUNCAN.—Dr. Ellis Duncan has just been appointed as superintendent of the Louisville City Hospital, vice Dr. P. C. S. Barbour, deceased. Dr. Duncan is a young man, but thoroughly qualified to undertake the duties, having assumed the duties of the office during some of the time that Dr. Barbour, his father-in-law, was incapacitated. Dr. Duncan has but recently returned from Porto Rico, where he went as assistant-surgeon to the First Kentucky Regiment (Louisville Legion), returning on sick leave. He made an enviable record with the regiment. He has also been appointed as assistant to the chair of abdominal surgery and instructor in gynecology in the Kentucky University Medical Department.

GREEN.—Dr. Waller O. Green has been appointed a clinical professor of diseases of the rectum in Kentucky University. Dr. Green was for several years the chief of the rectal clinic of the out-patient department of the Kentucky School of Medicine.

HEALTH REPORT.—Health Officer Allen has just made his report for the month of November. There were 326 births for the month, 181 males and 145 females, 299 white and 27 colored; there were 319 deaths and 69 marriages. The physicians to the poor made 483 visits; 111 nuisances were abated, and 336 animals were removed by the dead animal contractor. Forty-eight cases of scarlet fever were placarded and 35 cases of diphtheria. One hundred and forty-five vaccinations were made by the department, and a number of examinations of milk made, only two of these falling below the standard. In concluding his report, Dr. Allen expresses his satisfaction on the passage of the ordinance requiring the reporting of typhoid fever and whooping-cough and consumption, and expresses the desire that a competent veterinarian be appointed as live stock inspector.

Denver.

HEALTH OF THE CITY.—Cases of infectious and contagious diseases reported during the month of October: Diphtheria 53, with 7 deaths; scarlet fever 25, no deaths; typhoid fever 22, with 9 deaths; total number of deaths 158, of which premature and still-births were 15; cases of phthisis contracted elsewhere 24; death-rate per 1000 per annum 11.25; death-rate per 1000 per annum, excluding phthisis contracted elsewhere, 9.63.

METEOROLOGIC SUMMARY FOR OCTOBER.—Possible hours of sunshine, 345; total hours of sunshine, 280; mean barometer, 24.771; mean temperature, 49; total precipitation, 1.05; mean relative humidity, 41.0; number of clear days, 16; partly cloudy, 11; cloudy, 4.

POPULAR LECTURES.—Dr. Mary C. J. Love, the Chairman of the Department of Health and Hygiene of the Woman's Club of Denver, has arranged a series of lectures to be given during the winter by local physicians on the following subjects: "The Nervous System," S. D. Hopkins; "How We Breathe and How Our Blood Circulates," Josephine Peavey; "Intelligent Womanhood," M. C. T. Love; "Foods, their Chemical Significance and Values," Henry Sewall; "Nutrition and

Feeding of Young Children," Eleanor Lawney; "Puberty and Adolescence," Mary Barker-Bates; "Diseases of the Will, and Power of Suggestion, Hysteria and Hypnotism," J. T. Eskridge; "The Eye and the Ear, their Care and Protection in the Young," Jean Gale; "Women as Mothers," M. C. T. Love; "Sanitation and Hygiene of Home," W. P. Munn; "How Much Physiology and Hygiene Shall be Taught in the Higher Grades of Public Schools—Shall Men and Women be Employed to Teach Physiology to Unmixed Classes?" Leonard Freeman, Mary H. Barker-Bates.

TO PREVENT THE SPREAD OF CONSUMPTION.—The City Improvement Society of Denver has sent out the following note to all physicians residing in the city: "Realizing that physicians can do more than any one power to prevent the spread of consumption, and to insure sanitary reform in the matter of non-expectoration on the sidewalks, to the physicians of the city we therefore appeal for co-operation, that by instructing their patients not to spit on the sidewalks we may have a cleaner and more healthful city." City Attorney Norris has prepared a bill, as follows:

Be it enacted by the city council of the city of Denver:

Sec. 1. It shall be unlawful for any person to spit upon the floor, or any part of any street car or elevator, within the city of Denver.

Sec. 2. Any person violating the provisions of this ordinance shall upon conviction be fined not less than \$3 nor more than \$5 for each offense; and the conductors of all street cars and the pilots of all elevators are hereby authorized and empowered to enforce the terms of this ordinance.

Washington.

REPORT OF THE HEALTH OFFICER.—The report of the health officer for the week ended November 26, shows the total number of deaths to have been 92, 52 white and 40 colored. The principal causes were: Apoplexy, consumption, diphtheria, diseases of brain, heart and kidneys, pneumonia, typhoid fever. There were 97 births, 61 white and 36 colored. At the close of the week there were 127 cases of diphtheria and 117 cases of scarlet fever under treatment. The special report on the death from yellow fever shows that the death from this disease, which occurred on the 18th ult., was the first ever recorded in the District of Columbia. The deceased was a civil engineer and arrived in New York City, on the steamer *Allegheny*, November 16, from Greytown, Nicaragua, via Port Limon, Costa Rica, an infected port. The steamer touched the latter port November 7, and during the voyage the deceased was taken sick, but was able to pass the quarantine officers at New York City, arriving at Washington November 16, where he registered at a hotel, going immediately to his room. At three o'clock on the morning of the 18th, his condition attracted the attention of the hotel authorities, who summoned medical aid. Dr. A. Barnes Hove, formerly resident physician of the Emergency Hospital, responded, and upon seeing the black vomit and learning that the patient had been in a port infected with yellow fever, suspected the infectious character of the disease, and called consultation, which resulted in the positive diagnosis of yellow fever. The urine showed the presence of albumin, without casts, and an examination of the blood failed to determine the presence of a malarial parasite. The patient died comatose at two o'clock the same day. The postmortem held showed the characteristic lesions of yellow fever. The health officer does not anticipate the development of other cases in the District at this season. The usual newspaper excitement followed the report of the case, and as a result the nature of the disease has been discussed pro and con.

GEORGETOWN UNIVERSITY HOSPITAL.—Donation day at the new Georgetown University Hospital proved to be a great success. The friends of the Institution, and those interested in the care of the sick poor, sent large donations of money, food, medical and hospital supplies, all of which were gratefully received by the hospital authorities.

TO REGULATE DENTISTRY.—The dentists of the city have prepared a bill to further protect them in the practice of their profession, and will submit the same to Congress for action in the coming session. The bill provides for a local board of examiners to make rules and regulations, and pass upon the fitness of those applying for a certificate to practice dentistry in the District. It is proposed in the bill that examinations be held in June and December, and it provides that no corporation, not incorporated by Act of Congress, shall practice in the District without special permit from the Commissioners. A fine of \$30 is provided for violations. The Board will consist of five reputable resident dentists who shall elect their own officers and issue all licenses to practice. It also provides for the revocation of license, for just and sufficient cause.

Dr. IRVING C. ROSSE sailed for Europe on the 26th ult., for a few weeks' vacation.

Dr. J. J. ULLOA, of Costa Rica, and Major John V. R. Hoff, U. S. A., of Pan American fame, are visiting the National Capitol. Dr. Ulloa is with the Costa Rican President, now on official visit to the U. S. Government.

BOARD OF TRADE OF WASHINGTON.—At the meeting of the Board of Trade, held on the 30th ult., Dr. W. W. Johnson was appointed Chairman of the Committee on Public Health and Dr. H. L. E. Johnson a delegate from the Board to the meeting of the National Pure Food Congress which convenes in January next.

London.

A most remarkable and, from a medico-legal point of view, most important case, was reported to the Hunterian Society, on November 23, by Mr. J. H. Yargett. The stomach and esophagus of a child, at ten months, were shown, containing rather unusual foreign bodies. The patient had been brought to the hospital suffering from severe dyspnea and dysphagia, with a history of having suddenly choked while eating a piece of brown bread. Exploration with the finger and probe revealed nothing that would account for the dyspnea and, thinking that the fragment of crust probably present in some pouch of the esophagus, would soon soften, the child was kept quiet and carefully watched. In a short time the dyspnea subsided, although the dysphagia persisted, but the child seemed unaccountably weak and depressed, symptoms of broncho-pneumonia developed and it sank rapidly, and died in three days.

At the necropsy, the lungs were found extensively consolidated and the bronchial passages full of bloody mucus and mucus. Upon opening the stomach, two small corks were found, of about the size which would fit an ordinary two or three ounce bottle, and it was naturally supposed that one of these had injured the pharynx in swallowing and given rise to the trouble.

But when the pharynx was laid open to discover the site of the abrasions, the knife struck upon a much larger cork, completely imbedded in a pouch upon its posterior wall. The cork was of the ordinary cylindric shape, one and one-fourth inch long by three-fourths of an inch thick, and was so deeply sunk in the wall of the pharynx, just at its junction with the esophagus, that its anterior border barely projected into the cavity of the gut. The singular thing was that so large a foreign body could have formed a pouch in the wall of the pharynx and passed out of its lumen so quickly, so as to permit the passage of a probe, and even the taking of a certain amount of milk shortly before the child's death.

But the most interesting developments occurred at the inquest. It was discovered that the mother of the child had lost no less than five other children under two years of age, all of whom had been insured, as was also the case with the infant under consideration. Neither the mother nor the nurse in whose care the child was left during the day could give any light as to how the corks came there; on the contrary, they vehemently repudiated the suggestion that it had ever had

corks or bottles to play with, and even declared that there were no corks in the house and had not been for weeks! In spite of these facts, however, the sapient twelve declined to see anything suspicious in the case, and one of the jurymen gravely suggested that the corks might have got into the gullet by the doctor, who saw the child before it was taken to the hospital, using them to prop the child's mouth open while he examined it! Another nineteenth century Newton was sure that, a hospital being a place where sick folk did congregate, there must have been plenty of medicine bottles about from which the child could easily have gathered two or three corks. And with that low distrust of our profession which marks the vulgar mind, several witnesses had to be called and examined to disprove these asinine suggestions.

Finally, the "bulwark of our liberties" got itself delivered of the illuminating verdict that the child came to its death by means of corks in its stomach and gullet; that there was no evidence to show how the corks were introduced, but that the jury were of the opinion that they were in the child before Dr. — was called to attend it!! Comment is superfluous, but it would be well for the profession to bear this new possibility in mind in cases of sudden death in heavily-insured children.

Philadelphia.

RETURNED.—Dr. John Packard, who has been spending the past few months in Europe, arrived home during the past week.

IMPROVING.—Prof. John Ashhurst, who has been confined to his bed for the past few months, from two mild attacks of apoplexy, is now greatly improved and hopes are entertained for his complete recovery.

CONVALESCENT.—Dr. William Pepper, Jr., who has been suffering from typhoid fever for the past few weeks, at the University hospital, is now convalescent. He will leave about December 10 for a trip to Europe.

PHYSICIAN INJURED.—Dr. Robert M. Given, a member of the medical staff of the Pennsylvania Hospital, was recently thrown from his carriage, sustaining several lacerated wounds of the face and contusions. The coachman sustained a fractured leg.

MORTALITY STATISTICS.—The number of deaths during the week just closed was 399, a decrease of 50 over last week and an increase of 8 over the corresponding week of last year. Of the total number of deaths, 118 occurred in children under the age of 5 years.

HEALTH OFFICER AND QUARANTINE PHYSICIAN.—Owing to the results of the recent election and the selection of Governor Stone the two above-named positions will be left open unless the present incumbents are reappointed. The health officer of this city receives a salary of about \$7100 annually, while the quarantine physician receives \$5000.

STERILIZED MILK SOCIETY.—The Sterilized Milk, Ice and Coal Society, through its founder, has asked for contributions in order to carry on its work during the coming winter. When it is considered that through the influence of sterilized milk the death-rate of children is greatly reduced, it will be seen what an instrument for good this Society may become.

MEMORIAL MEETING.—A meeting commemorative of the life and works of the late Dr. William Pepper was held in the chapel of the University of Pennsylvania November 29. The committee having the matter in charge was composed of representatives from the University of Pennsylvania, American Philosophical Society, Franklin Institute, Academy of Natural Sciences, and other public institutions of the city. Governor Hastings presided, and speakers were present to represent the different institutions with which Dr. Pepper was identified.

SMOKER TO UNIVERSITY ALUMNI.—The Alumni Society of the Medical Department recently gave its semi-annual "smoker." A spirit of patriotism pervaded the banquet hall and Dr. John Guiteras spoke in glowing terms of the victorious army, while Dr. Edward Martin complimented the "woman

nurse," who did much to lessen the pangs of disease and keep down the mortality.

FOOTBALL CASUALTIES.—One of the papers here has kept a list of the casualties reported during the past year, as follows: Number of collar bones broken, 5; legs broken, 4; ribs broken, 4; skulls fractured, 3; torn ligaments in leg, 3; shoulders broken, 2; besides broken nose, concussion of the brain, ruptured kidney, broken wrist, collar bone dislocated, knee dislocated, cartilage of ribs torn, ankle broken, and thumb broken. Internal injuries and twisted legs are hardly considered as casualties.

DIPHTHERIA COMMON.—The northern section of the city, particularly around Nicetown, is being stirred up over the spread of diphtheria among school children. Investigation recently made showed that several children attending St. Stephen's Roman Catholic church were suffering from the disease, and one had died, while at the Asa Packard school two deaths had occurred. It is stated that the greatest care is taken at the schools to prevent the disease from spreading, and that upon the first observance of any complaint the children are immediately sent home with a note to call in a physician. Several children attending the Cayuga school have also been afflicted with the disease. Dr. Charles S. Means, a member of the Common Council, recently introduced a bill providing that all the children who attend the public schools of this city, after Jan. 1, 1899, shall be injected with antitoxin, for the purpose of immunization from diphtheria, and further, that the Director of Public Safety be directed to instruct the Medical Inspector of the Board of Health to enforce the provisions of this ordinance.

GOVERNMENT ALLOWANCE FOR SICK SOLDIERS.—At a recent meeting in the rooms of the National Relief Association several representatives of the hospitals took the position that since the hospitals volunteered to care for the soldiers, therefore they would accept no compensation whatever. Major Peyton, who has charge of all sick soldiers in Pennsylvania, stated that the Government was unwilling to accept charity for its soldiers and desired to pay all who have had charge of the work. Those hospitals and other organizations who have defrayed the expenses of hospital trains to Camp Meade and elsewhere will not be reimbursed for the outlay. It was finally agreed that the Government would pay the hospitals at the rate of \$1.00 a day for each sick soldier. A vote of thanks was passed for the courteous treatment given the hospitals by the War Department, as well as to Major Peyton, the representative of that Department.

FINANCE COMMITTEE.—The Finance Committee of the city council has been working at the usual budget of expenditures for the coming year, but about the only two items of interest to physicians are the salary attached to the position of physician to the county prison and appropriations for charity and corrections. It seems that the actions of prison inspectors have been called in question relative to the fact that Dr. Butcher's salary as physician has been raised from \$1500 to \$1800 a year. The increase was referred to a sub-committee. As to charities and corrections, the department has asked for an increase of \$60,000 for the purpose of enlarging the insane department of Blockley Hospital. While the appropriations for the Bureau of Charities and Correction were \$481,968 in 1898, it is hoped that \$597,918 will be appropriated for the coming year.

GERMANTOWN CHILDREN'S HOSPITAL.—The board of managers of the Children's Hospital of Germantown is still busily engaged in raising the necessary funds for the establishment of the institution on a firm basis. An appeal for contributions has been made with a liberal response. It is now proposed to raise sufficient funds for the present needs by giving a series of entertainments, and up to date arrangements have been completed for this purpose.

SOPORIFIC REFORM.—Whether or not the cares and vexations incidental to public and private receptions are conducive to long existence may be demonstrated by the soporific reform recently set on foot in a neighboring city and taken up by society dames in Philadelphia. At any rate, many leading lights in upper tandom applaud the movement and say, "give us more sleep." While at present the movement is only a fad, in time it may prove to be beneficial, not only to the devotees, but to posterity as well.

CONTRIBUTIONS TO THE GERMAN HOSPITAL.—While Donation Day was most inauspicious for visitors, a number of contributions were received by mail, which makes the record compare favorably with that of former years. The donations consisted of a large quantity of groceries, boots, shoes, dry goods, etc., and \$7,294.36.

PRESBYTERIAN HOSPITAL.—Owing to the fact that this hospital has been lately taxed to the utmost in caring for charity cases and soldiers, and to meet the expenses brought about by the construction of new operating-rooms, a receiving-ward, and the Dulles' memorial ward, it asks for an increase of income amounting to \$20,000. In the appeal it is stated that \$250,000 added to the permanent funds of the hospital would enable them to make good use of all appliances and to meet the more pressing demands made upon the service.

NATIONAL RELIEF CONTRIBUTIONS.—Mr. George C. Thomas, treasurer of the National Relief Association, makes the following report: Cash previously acknowledged, \$78,487.29; cash and supplies, \$769.19; value of supplies to date, \$40,345; grand total, cash and supplies, \$119,601.48. At a recent meeting of the Executive Committee, officers were notified that they would soon be expected to file their reports, to be turned over to the Government. Governor Hastings made a speech and tendered thanks to the Commission in behalf of the State for the excellent service they had rendered. It is stated that 431 families and 1386 individuals are still being cared for by the Commission. A list was also made of the number of soldier patients admitted to the Philadelphia hospitals to date, there being 2238 men, with 108 deaths.

OF MEDICO-LEGAL INTEREST.—A case which has attracted considerable public interest is now being tried in the court of oyer and terminer in this city. Mrs. Mary E. Zelter stands charged with poisoning her aged husband. At the trial expert witnesses were present to give testimony regarding the nature of certain drugs apt to cause the symptoms and pathologic conditions set up by certain persons. Dr. John Marshall, dean of the medical faculty of the University of Pennsylvania, was one of the first witnesses and stated that he had been supplied with portions of the liver, brain, intestines and muscular tissue of the exhumed person, and that over half a grain of strychnin had been thus obtained from these tissues, which he thought was consistent with a poisonous dose of the drug. Dr. Henry W. Cattell, coroner's physician, testified that he had conducted a postmortem examination. Dr. Horatio Wood was then called, and in reply to a question by the district attorney, stated that he was thoroughly acquainted with the effects of strychnin. Having heard the testimony of previous witnesses that the drug had been found in the tissues of the body exhumed, he thought it practically certain that only a small proportion of the poison had been obtained. On cross-examination his testimony remained unshaken.

UNCOMMON CAUSE OF DEATH.—Paul Miller, a child 6 years of age, while feeding chickens, placed a grain of corn in his mouth. It descended into the trachea; all efforts to remove it were futile, and death ensued.

OVERCROWDING OF INSANE.—While the accommodations at Blockley Hospital were originally intended for only 1000 persons, there are at present 1400 insane confined within the different wards.

CONVALESCENT TYPHOID PATIENTS.—Nine soldiers who have been treated for the past few weeks for typhoid fever, at the Presbyterian Hospital, have been discharged. The men were brought to this city during the month of October from Camp Meade.

RACE QUESTION RAISED.—Students of the Jefferson Medical College have passed a resolution providing that a committee be appointed to determine whether or not there is a gentleman not altogether white who enjoys the facilities offered by that time-honored institution. If such is the case an earnest protest will be made to the dean.

DIPHTHERITIC PARALYSIS.—George Cromm, a child four years of age, after eating a piece of scrapple, suddenly died. A history of having recently suffered from diphtheria, and a subsequent necropsy, led the coroner's physician, Dr. H. W. Cattell, to the belief that death resulted from diphtheritic paralysis.

CONTRIBUTION TO UNIVERSITY LIBRARY.—Dr. S. Weir Mitchell has presented to the university library two very important historic documents which have come into his possession. The documents were given Provost William Smith, conferring upon him the power to collect funds for the College and Academy of Philadelphia (now the University of Pennsylvania), also to James Jay power to collect similar funds for the College for the Province of New York (now Columbia University). One is dated April 30, 1764, and the other March 13, 1762. The documents are signed by the Archbishop of Canterbury, Archbishop of York, Lord Bishop of Winchester, Provost Smith and the Rev. Dr. Chandler. Various receipts are attached showing that in one instance a contribution of £500 was made by Thomas Penn.

SMALLPOX.—Five cases of smallpox are reported. For several months past urgent measures have been made to determine how many school children were properly vaccinated in order to keep down epidemics of this kind, but the law has been much evaded. The school authorities of the immediate neighborhood have been notified so that the proper precautions may be taken.

UNWHOLESOME MEAT SUPPLY.—At a meeting of the Woman's Health Protective Association, Dr. W. Horace Hoskins, president of the Veterinary State Board of Examiners, is quoted as saying that a thorough inspection has revealed the fact that meat supplied to this city is frequently unwholesome; in other words, that Philadelphia is a dumping ground for "worn out cows."

ASYLUM POLLUTES SCHUYLKILL.—At the last meeting of the trustees of the State Hospital for the Insane, Dr. Benjamin Lee, secretary of the State Board of Health stated that from his investigations, made some time ago, it was found that deleterious material from that institution was allowed to flow into the Schuylkill, and he therefore requested that the condition be relieved. The secretary of the trustees, however, made reply that the Board was powerless to remedy the evil on account of lack of funds. It is now stated that the whole question will be carried before the State Legislature in order that a proper bill may be passed to abate the evil.

CHANGE OF ADDRESS.

Comstock, H. C., from Sioux City, Iowa, to Hutchinson, Kan.
Corkery, T. L., from Fairfield, Ind., to Wilmington, Ohio.
Chaddock, C. G., from 2906 to 511 N. Garrison Ave., St. Louis, Mo.
Crandall, G. C., from 610 to 511 N. Garrison Ave., St. Louis, Mo.

CHICAGO, ILLINOIS, DECEMBER 17, 1898.

No. 25.

ORIGINAL ARTICLES.

THE DIETARY OF HEART DISEASE.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY ROBERT H. BABCOCK, A.M., M.D.

CHICAGO.

Nothing is more important in the management of cardiac affections than the regulation of the diet, which should include the determination of the amount as well as the quality of the food ingested. At the very outset we are confronted by certain perplexing problems that arise from circulatory disturbances in the digestive organs and by want of definite knowledge concerning alterations in secretion and absorption brought about through venous stasis. It is still more complicated because of alteration in the metabolic processes incident to changes in the blood-supply of the various organs and tissues. Indeed, the problems confronting us are so complex and have been so inadequately worked out as yet by physiologic chemists that, even were there no time limitations to this paper, I could not hope to do more than consider this subject very superficially.

In the first place, what are the effects of passive congestion on the digestive viscera? From analogy with the effect of stasis on secreting organs, as the kidneys, it is likely that the digestive juices are changed in both amount and quality. Even if the chemistry of these secretions were not altered, the catarrhal swelling of the mucous membrane induced by passive hyperemia would hinder the free flow of the bile and pancreatic juice into the duodenum, which, together with the collection of thick, tenacious mucus in the stomach, would interfere with the proper digestion of the food. Moreover, the congestion, and in advanced cases, the edema of the walls of the hollow viscera, impedes or abolishes their proper peristaltic movements. This renders decomposition of the ingesta unavoidable under the influence of heat, moisture and micro-organisms introduced with the food. The various acids, fatty and otherwise, thus engendered still further irritate the gastroduodenal mucosa, while the gases of decomposition still further distend these viscera. Thus a vicious circle becomes established that augments the evil primarily attributable to disturbed circulation. This is by no means the only aspect of the case; toxins are developed which must either be destroyed in the liver or pass through into the general blood-stream and exert their noxious effect upon the heart and nervous system. We are apt to dwell chiefly on the mechanical disturbances arising in the stomach and intestines, yet the pancreas is an organ that must suffer greatly in function. What modification of its secretion takes place we do not know; yet clinical observation seems to justify the inference that the amylase and fat-splitting fer-

ment are more unfavorably influenced than is the proteolytic ferment. Nevertheless, it would be unreasonable to assume that this escapes altogether. Pancreatic digestion is undoubtedly impaired, and consequently the portal vein carries to the liver a mass of toxins together with the products of incomplete or faulty digestion.

This brings us to the most difficult, because the most obscure part of this complicated subject—the effect of passive hyperemia on the liver. This organ differs greatly from other glands, since its functional activity does not depend wholly on its arterial blood-supply, but is determined in large measure by the character of the blood in the portal vein and the activity of its flow. To give an illustration: The constitution of the bile and the rapidity of its secretion depend upon its absorption from the intestine and its return to the liver. If, now, in consequence of stasis in the gastroduodenal and other veins that empty into the portal vein, the bile discharged into the duodenum be returned slowly and inadequately to the liver, the bile thereafter secreted will be watery and deficient in mineral matters. And although the secretion of this fluid is but a minor part of the hepatic function, deterioration in quality and diminution in its quantity exert a baneful effect upon the intestinal contents. Again, if in consequence of defective gastrointestinal digestion the portal stream be loaded with toxins and the products of such faulty digestion, it is reasonable to assume a resulting derangement in the elaboration of urea and the manufacture of sugar, etc. Very probably also the ability of the liver to cope with toxins will be impaired and numbers of them will pass through into the general system. The anemia so commonly shown by cardiac patients seems to me not unreasonably explicable on the hypothesis that the liver is unable to utilize nucleo-albumins in the manufacture of iron, as well as that the hemoglobin is destroyed by some ferment generated in the intestines. Patients with heart disease are frequently found to suffer with symptoms of Haig's uric-acidemia, and Husche has demonstrated an accumulation of uric acid in the system during loss of compensation, and on the other hand, an increased elimination of it after restoration of compensation. This accumulation of uric acid must depend upon lessened or altered cell activity, as would be naturally expected to result from impaired circulation. Oxidation is defective, partly through reduction of hemoglobin, partly through sluggish capillary circulation, and hence, another factor in the derangement of the metabolic processes. On every side, therefore, we encounter problems of nutrition which we are not able to solve, yet which we must meet in the dietetic management of our cardiac patients. Evidently all we can do is to work along lines conforming with well-established principles.

It is presupposed that the foregoing considerations

do not apply with equal force to all cases of heart disease, inasmuch as the same lesion does not always manifest equal severity of symptoms, any more than do the different lesions. Therefore it is not necessary to enforce rules of diet with equal rigor in all cases. Broadly speaking, therefore, it will suffice to divide all cases into two groups; the one in which compensation is preserved, the other in which it is lost, more or less completely. Although carefulness of diet is advisable, even in the former, to preserve the heart from still further danger, still, considerable latitude may be permitted; but so soon as a loss in the equilibrium of the circulation becomes apparent, dietary restrictions should be enforced. The remainder of this paper is intended to apply particularly to patients whose cardiac weakness necessitates strict medical supervision.

When appetite flags and the patient can not eat heartily at the regular meal hours, it is usual for the physician or friends to think his meals must be reinforced by milk, egg-nog and the like, midway between. In some instances nourishment is administered every two or three hours. Such is undoubtedly a mistake. The congested and perhaps edematous walls of the stomach can not by energetic peristalsis empty the chyme into the duodenum as rapidly as normal, and the conditions for decomposition are so favorable that, if additional food be taken before the stomach is ready for it, serious disturbances are sure to result. A feeling of faintness or craving at the epigastrium, often described as an "all-gone feeling," may be mistaken for an indication that food is needed, and as these patients are often tormented with thirst, liquids of all kinds are poured down into the already distended and irritated viscous at irregular intervals. Abdominal distension, eructations, flatulence and increased dyspnea add to the patient's distress. The first rule, therefore, should be to make five and a half or six hours elapse between the taking of solid food; and this should include milk, since by curdling in the stomach it is converted into solid food. So simple a restriction as this will often work wonders in regulating the digestion and removing the thirst and epigastric gnawing. If nourishment between meals is needed, it can be in form of somatose, nutrose and the like, that are not open to the objections urged against solid articles. Nutrient enemata can also be administered during this interval. In my experience, it is beneficial for the invalid to drink a cupful of hot water about an hour before the next meal, as it seems to aid in the expulsion of the chyme. Skillful massage of the stomach from two to four hours after meals is likewise highly serviceable to the same end, besides having been shown by Boardman Reed to augment the amount of hydrochloric acid.

The next step is the restriction of the amount of fluids ingested, particularly with meals. In severe cases patients should not be allowed to drink more than six ounces of fluid, while even in mild ones ten ounces ought to be the maximum limit. This does not mean water in addition to whatever other beverage has been prescribed, but all fluids combined. The purpose of this is to prevent undue distention of the stomach. When edema is imminent or actually present, the total amount of liquid ingested in the twenty-four hours must be reduced to the smallest quantity compatible with the needs of the system. It will generally be found that such a restriction will aid in the removal of dropsy. Milk should be

regarded as liquid, for although its casein is coagulated, it must be remembered that 87 per cent. of the milk is water. Patients should likewise be restricted in the amount of solid food, a good and usually sufficient rule being that they leave the table feeling that they can eat more. A little, well digested, is worth far more than a good deal, poorly digested. This not only lessens the likelihood of distending the atonic organs, which it has been shown, further decomposition, but it tends to prevent the still greater cardiac embarrassment occasioned by post-prandial pressure. Such restriction must not be carried to the degree of starving the patient; and yet, if the quality of the nourishment be judiciously selected, it will often surprise one to find how small a bulk will suffice, nay, how it will minister to the patient's comfort.

In considering the various beverages and viands that should constitute the menu for this class of invalids, I think it best to deal with the subject in a general way rather than to attempt to set out the composition of individual meals. Tea and coffee should be weak, the amount of sugar and cream they contain being determined by the degree of digestive disturbance. Cocoa or broma is preferable to chocolate because less rich, and when made with milk is nutritious. If wines or liquor are thought advisable, they should be freely diluted with water. Buttermilk, or malted milk often makes a valuable addition to a meal, and generally agrees well. Effervescent drinks are objectionable on account of the distention they occasion; for this and other reasons I regard malt beverages as injurious. Nevertheless, they may sometimes be allowed when particularly ordered and their bitter taste stimulates a flagging appetite. Iced drinks should not be permitted, neither should fluids be very hot, as a medium temperature is undoubtedly better for a weak stomach. The question of soups and broths must be governed by the state of the kidneys and the habits of the patient. When nephritis exists, stock soups and meat extracts are to be rigorously interdicted. It should never be forgotten that beef-tea and the like are stimulants and possess no real food-value. Cream soups, or purées, as they are called, are not open to the same objection, and are highly nutritious. All these are fluids, however, and when taken in connection with solid articles of diet should be limited in amount, lest they blunt the appetite for what is to follow.

There are two considerations why the carbohydrates must be allowed but sparingly. One is their tendency to undergo fermentation and give rise to flatulent distention of the bowels, and the other, their ready oxidizability, by virtue of which latter quality they appropriate the oxygen required for the utilization of the nitrogenous elements of the dietary. Proteids are indispensable to the maintenance of the heart muscle, and therefore must always constitute a relatively large proportion of the food of cardiac patients. Yet circulatory derangement reduces metabolic activity of the cells; the physiologic leucocytosis becomes excessive, and uric acid and other members of the xanthin group resulting from the splitting up of the nuclein are apt to occasion annoying symptoms which we term "lithemia." Inasmuch as starches and sugars can not be withheld entirely they must be given in as unobjectionable a form as possible. Bread is best taken as toast or zwieback, light crackers, the so-called "shredded biscuits," etc. Entire wheat flour is far preferable to patent flour, since the latter contains little but starch; and if toast and the like grow

monotonous, baking powder muffins or rolls made very light and thoroughly baked may be substituted. Potatoes, both white and sweet, rice, cereals, and the multifarious combinations of flour, butter and sugar whether with or without eggs and milk, known as cake, griddlecakes, etc., are inadmissible. Sweetmeats, including candy and preserved and canned fruits, are likewise to be put under the ban. When fruits are desired or indicated, they are best in their natural state, but even then, must be fully ripe and fresh. Apples are particularly good, because of their relatively large percentage of nucleo-albumin; baked they are often better tolerated than uncooked.

Most of the green vegetables are valuable additions to the dietary, either because rich in proteids and other nutritive principles or on account of their serving as relishes and containing various salts essential to the organism. Peas, lentils, string beans and spinach are said to be relatively rich in iron-forming principles. Tomatoes, cabbage, cauliflower, turnips and kindred varieties are apt to disagree, but if well borne may be permitted. Asparagus, when not contraindicated by renal disease; celery, mushrooms, lettuce, greens of various kinds and young carrots are allowable, while onions, cucumbers, tender radishes and olives may be left to individual desire or idiosyncrasy. Beets are rich in sugar, but otherwise are not generally objectionable. The chief desideratum as regards all such vegetables is their freedom from liability to occasion flatulent distention, as do articles rich in starch and sugar.

Of foods rich in nitrogen, beef and pork head the list, but perhaps are not so easily digested as veal, lamb and mutton, which are excellent when not too fat. All meats should be roasted, broiled or stewed, not fried; but however prepared, they should be as free from gravy as possible and ought to be sufficiently well done to have destroyed the germs of decomposition, through whose action during the time of hanging the meat becomes tender. Fowl and game birds form a capital adjunct to the heavier meats, as also do fish and most kinds of shellfish, particularly oysters, properly cooked. Some of the salted meats and fish, when not too rich, provide appetizing and nutritious dishes. Canned salmon, sausages and the like are too rich in fat, and are apt to cause eructations, whereas fresh tripe is said to be easy of digestion. Cheese is to be forbidden excepting cottage cheese and some light cream cheese, as neuchatel. Eggs are admissible, and when properly cooked are very digestible.

In conclusion, a few words should be said concerning the dietary of two classes of cases: one, in which the cardiac affection is complicated with nephritis; the other, in which it is secondary to arteriosclerosis, with or without angina pectoris. In the former, highly nitrogenous articles are clearly inadmissible; yet carbohydrates promote digestive disturbances. Therefore, a compromise must be made, or milk must constitute the major part of the dietary. When arteriosclerosis is the main difficulty, we are confronted by another problem. We must nourish the overburdened heart, yet must avoid administering foods rich in lime salts, otherwise the sclerosis will be increased. Eggs, cereals and articles rich in phosphates are to be denied, or only permitted sparingly. Moreover, greater than ordinary care to avoid indigestion is imperative, since the products of defective digestion and faulty metabolism will set up vasomotor spasm. The successful management of cardiac disease often

consists in the removal of whatever may serve as a hindrance to the performance of the organ. So simple a matter, therefore, as heightened blood-pressure may make powerfully against the restoration of an unsound heart.

Finally, it may be one thing to lay down a theoretic dietary for patients with heart disease, but it is quite another thing to carry it out in practice. Not only is our knowledge deficient of the physiologic chemistry of pathologic conditions; but we are hampered, even checkmated, by the notions, whims and prejudices of both patients and their friends.

103 State St.

DISCUSSION.

Dr. BABCOCK—For the purpose of calling forth discussion I should like to direct attention to one or two points. The first is, What would be the value and desirability of nuts in the dietary of heart patients? Through an oversight, not discovered until after the completion of my paper, I omitted to include nuts. These are generally considered difficult of digestion; but I am convinced that this depends much upon individual idiosyncrasy. Nuts are rich in proteids that might well replace animal foods when these latter disagree, and are poor in carbohydrates except fats. Consequently, those kinds that contain the smallest percentage of fat ought to prove suitable for persons with heart disease, if not eaten in excess. The second point is the cause and treatment of the anemia so common in this class of patients. Is the hypothesis tenable that the liver is unable to utilize the nucleo-albumin of the food? Are the usual therapeutic preparations of iron, whether organic or inorganic, likely to prove of benefit? I am free to confess that I have become very skeptical as to the ability of the organism to assimilate iron except as obtained through the food; indeed, I rarely, if ever, prescribe it to my heart patients on this account.

Although as stated I do not administer iron to my cardiac patients with any expectation of its being assimilated as such, yet I feel bound to admit this contradiction, that I sometimes order it for its effect upon the gastro-intestinal tract in the way of stimulating appetite and digestion and thereby improving nutrition and indirectly overcoming the anemia.

As regards Dr. Whittiker's cases treated with iron, it might well be urged that the improvement was due to the rest and improved nutrition. It is conceivable that under such circumstances the heart-muscle might regain sufficient force to carry on the circulation in a more satisfactory manner; when the dropsy might at length disappear and the patient even lose all appearance of anemia, so that to my mind it does not furnish conclusive evidence of the improvement in these cases having been wholly due to the iron. The point advanced by the chairman, of the anemia being due largely to defective oxygenation of the blood is a good one, is worthy of careful consideration, and may furnish a valuable hint in the treatment of the anemia.

SUGGESTIONS ON THE DIETETIC TREATMENT OF GOUT.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY DANIEL R. BROWER, A.M., M.D., LL.D.

Professor of Mental Diseases, Materia Medica and Therapeutics, Rush Medical College, University of Chicago; Professor of Diseases Nervous System, Woman's Medical School, Northwestern University; and in Post-Graduate Medical School, CHICAGO.

The great Fothergill and Garrod taught us that uric acid was the causative factor in gout; that it was formed by the metabolism of nitrogenous waste; that it represents a lower degree of oxidation than urea; that uric acid and its salts, being insoluble, are much less easily eliminated, and hence they accumulate in the system; that it is in the liver the splitting up of peptones into glycogen and waste, azotized substance takes place, and its insufficiency causes the diminished oxidation that produces uric acid instead of urea. Haig, in his masterly treatise on uric acid, accepts this theory. This tracing of gout to an excess

of nitrogenous ingesta results in the exclusion of this important group of alimentary principles from this class of patients.

This origin of uric acid, as the exclusive one, can not be maintained today, for we know that much, if not all, of this product comes from the oxidation of the nuclein of the blood corpuscles, and that uric acid is not the sole etiologic factor, but that the uric acid group of leukomains is of great importance. The defects of metabolism which produce the phenomena of gout are neurotic in origin and gout is a neurosis. Not only do we find excessive formation of the uric acid group, but a deficient alkalinity of the blood, and this means diminished solvent power and the precipitation of the compounds in the tissues. With the annihilation of the old theory of the origin of uric acid and the etiology of gout, a review of the principles of diet in the disease has become necessary.

It is true of gout, as of every other disease, that the diet must be made to suit the patient. The old adage, "one man's meat is another's poison," is emphatically true here, so that while the diet of Haig may suit some cases, yet the very opposite, or a diet exclusively of animal food, after the "Salisbury" method, for example, is the best for other cases.

The object of this paper is to insist upon a much more liberal allowance of the albuminoids than the dietaries of Haig, Garrod or Fothergill and their followers permit. The functional activity of the body is largely dependent upon the albuminates, which are necessary to the formation and repair of the tissues and fluids of the body; they regulate the absorption and utilization of oxygen, and contribute to the production of muscular and nervous force and heat, and hence must be of great importance to these patients. Lower the nervous tone and you but add to the danger. The source from which the body can most easily obtain the albuminoid matter is animal food. The amount of this food that should be permitted will usually be less than that used by the normal individual, and yet the extent to which such a reduction can be carried with impunity will depend upon the digestive peculiarities of the individual. The man of sedentary habits requires less than the man leading an active life. An exclusively vegetable diet should be advised only in the exceptional cases.

The consumption of food of all kinds should be minimized. Ben. Franklin's rule of always rising from the table with an appetite is the rule for the gouty. They should consume only enough to nourish the body and maintain its functional activity. Unfortunately for many of them, they pass into middle life with the vigorous appetite of early life and, unrestrained, lay the foundation for obesity, always a calamity for these unfortunates. Sugar, starchy and fatty foods, should be taken in moderation, because they interfere with complete metabolism of the albuminates. This is especially true of sugar; it is as detrimental to the gouty as it is to the diabetic, and for it saccharin can well be substituted, because it not only satisfies the craving for sweets, but also acts as an antiseptic and diuretic, thereby diminishing the danger of auto-intoxication and promoting elimination. The starchy foods, readily converted in the body into sugar, are as objectionable as sugar, and giving rise, as they so frequently do, to defective intestinal indigestion and resulting auto-intoxication, will lay the foundation for acute seizures. Fatty foods are of benefit to some because they satisfy the appe-

tite, and thereby diminish the total quantity of food eaten, but, as is well known, we must remember that under the influence of fat, tissue waste is diminished and less oxygen is taken into the system. This capacity to diminish albuminous metabolism may be very well for the lean, who can digest them, but bad for those who are inclined to corpulency. Eggs should be taken in moderation; there are some in whom they will produce, in small quantities, toxic symptoms. The large amount of fat they contain places them in the above category. Cheese is to be avoided, as the most concentrated of the albuminates, and because of the lactic and fatty acids it contains. Tomatoes, asparagus, rhubarb and strawberries, tending to produce an excess of oxalates, are to be avoided. In short, the great principles to be considered are: 1, abstemiousness in all things; 2, non-restriction of the animal albuminates which are so essential to the nutrition of the body and so comparatively easy of digestion; 3, withdrawing from the dietary the saccharine, starchy and fatty foods that check metabolism and diminish oxidation.

Among beverages we must always remember milk first; it is a very desirable food. The water used should be as free as possible from mineral matter; distilled water being the ideal. There is advantage in taking it hot a half-hour before meals and at bedtime.

The question of the use of alcoholic beverages is important and often difficult to decide. There are many gouty persons who should become total abstainers, and there are others who will be greatly benefited by the moderate use of alcohols. Beer, porter, stout, the sweet and sherry wines, such as champagnes, ports, sherries, Madeira and Burgundy, should be avoided. Moselle, light hock, the light Hungarian wines and claret, especially diluted with an alkaline table water, are permissible. For many whisky, brandy, Scotch whisky, or a gin, well diluted with an alkaline water, is the best form of alcohol.

PHYSIOLOGIC PRINCIPLES UNDERLYING INFANT DIETARY.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY R. O. BEARD, M.D.

PROFESSOR OF PHYSIOLOGY, DEPARTMENT OF MEDICINE, UNIVERSITY OF MINNESOTA.

MINNEAPOLIS, MINN.

No subject in general medicine has been more prolific of literature in the past and less fruitful of practical results in the present than the question of infant food and infant-feeding. Infancy is still a prey to gastro-intestinal disease. Thirty-five per cent. of the children born, die within the first three years of life of disorders of the alimentary tract or their sequelæ. No satisfactory explanation of this mortality has ever been given, saving that of prevalent dietetic error. No theory accounts for this condition other than this: that out of the great mass of varied experience, the medical profession has evolved no scientific system of infant dietary, has been guided by no sound physiologic principles in the selection, preparation and feeding of infant food.

After an endeavor, maintained for fifteen years, to meet this default and to remove this reproach from the practice of medicine, the writer ventures to present to this body certain foundational facts to which his daily practice has been adjusted and which an

almost unbroken success in infant-feeding and a nearly complete abolition of infant mortality from gastro-intestinal disease have sustained. The hope that one has succeeded in the solution of a problem, which others have so repeatedly failed to solve, would be rash indeed if it were not supported by the test of persistent trial. These facts will be presented in a brief outline form which will afford convenient openings for criticism.

The nursing mother and the individual nursing infant are normal elements in a physiologic equation. Under health conditions these elements are closely correlated. This correlation begins, not with parturition, but with impregnation. The metabolic changes leading up to lactation are initiated with the beginning of pregnancy. The nutritive events which occur in utero are associated with, are directive of, the metabolic events going on in the mammary gland. Evidence of this is seen in the fact that the premature termination of gestation determines an immature climax of functional activity in the breast. In the rabbit and in the cat, the writer has frequently noted the occurrence of structural changes in the gland and the rapid development of an abortive secretion of milk as the results of an induced abortion in the early stages of pregnancy. Clinical observations upon the human confirm this physiologic analogy.

It follows that errors or disorders of pregnancy are frequent causes of failure in the metabolism of the breast, are points of departure from which proceeds a future lack of correspondence between maternal supply and infantile demand. In the normal mother, after parturition, the output of the gland, both in the matter of quantity and in the matter of quality, corresponds with and varies to meet the needs of the infant. Human milk is not of stable composition, a fact which accounts for the uncertainties of analysis.

It must be insisted that this physiologic equation is, in each case, a personal one. In the same mother, with successive children, the largest variations in the quantity and in the quality of the milk-supply are to be observed and this under equally good conditions of maternal health. The quantity of the output corresponds closely with the capacity of the infant's stomach; its quality with the nutritive needs of the child. At successive stages in the entire lactation period, quantity and quality thus keep step, up to a physiologic limit, with the metabolic history of the infant.

Following in the footsteps of Frolovski, the writer has studied and recorded series of cases with reference to this correspondence. Difficult as it is to estimate the capacity of the stomach, postmortem, there is, nevertheless, a close correspondence between the results of measurements of the dead organ in infants, of certain ages, and the estimations, by graduated feeding, and by easily induced emesis immediately after feeding, of stomach capacities in the living child at similar periods of infancy. An equally striking relationship has been observed between these capacities of the infant stomach, so determined, and the measured yield to the suction-pump of the active loaded mammary glands at similar periods. Marked as are these variances in quantity, no less so are the changes in quality, in the proportions of proteids, fats and carbohydrates observed in the human milk at successive stages of lactation.

The responsiveness of the mammary gland to intra-uterine stimuli before parturition and to the infantile demands after birth is not difficult to understand

when the highly developed, typical quality of its metabolism, second only to that of the germinal epithelia, is considered. Its similarly sensitive response to influences disturbing of its metabolism is characteristic and accounts for the frequent failure of lactation. Into the many causes of this metabolic failure it is unnecessary to go. Suffice it to recognize the fact and to see in this disturbed physiologic equation the necessity for the study of a scientific substitution of the normal infant food. The artificial feeding of infancy is a most delicate problem, into the solution of which enters the appreciation of those conditions of quantity and quality in the normal supply upon which emphasis has been put. But that is not all. It turns equally upon an understanding of the conditions of the physiologic demand, upon a better knowledge than has yet been attained of the digestive processes of infancy. They are not those of adult life. They contribute, not merely to the maintenance of the balance between waste and repair; they minister to a constructive metabolism which altogether overshadows destructive tissue-change. Observation alike of the feeder and the food has brought out, quite clearly, some features of infantile digestion.

In the carbohydrate field, nature fortunately provides a fully elaborated supply, for the amylolytic ferment of the saliva is inactive while that of the pancreatic juice is absent in early infancy. Consequently, the non-digestion of starch, the readier digestion of dextrans, the non-inversion and the easy fermentation of cane-sugar, the non-fermentation and the ready absorption and inversion of lactose, are the characteristics of carbohydrate digestion.

In the proteid field, the ready digestion of the lactalbumin and caseinogen of the human milk is to be noted. This is secured by the joint action of the pepto-hydrochloric acid of the gastric-juice and of the trypto-carbonate of soda in the pancreatic juice.

To Professor Chittenden of Yale University, physiology is indebted for the use of the first term, descriptive of the loose chemic combination which exists between the pepsin and the hydrochloric acid. The writer has ventured to suggest the use of the latter term as equally suggestive of the necessary association existing between the trypsin and the sodium carbonate of the pancreatic juice.

The statements of recent writers on infant hygiene that hydrochloric acid does not exist in the normal stomach of very early infancy, can be very simply disproved. It does not exist in free form, and even in the normal gastric juice of adult life is this true. It is existent, nevertheless, as Professor Chittenden has suggested, in association with pepsin. In that relation it will not respond to the usual color tests for free hydrochloric acid. When, however, by the application of heat to 65 degrees C. the pepsin is destroyed, the hydrochloric acid is dissociated from it and can then be detected by these usual tests. In a series of observations upon the gastric juice, taken from seven healthy infants during the first week of life, the writer has clearly determined the effective presence of hydrochloric acid by this method. The agents of proteid digestion exist, then, alike in the stomach and in the small bowel of the infant, even before birth.

The digestion of the proteids of cow's milk by the human infant is a very different matter. Lactalbumin and caseinogen in human milk are one thing; in bovine milk they are another. Proteids of very simi-

lar character, which go under the same names, but are existent in the several tissues and body-fluids, often demand differentiation. Creité, Lehman, Weiss and others have shown that the serum-albumin of one animal is foreign to and toxic in the blood of another and that its introduction is commonly followed by albuminuria. In view of these facts, it is easy to understand that the proteids of the milk of one species may undergo doubtful digestion in the infantile food-tract of another.

In the field of fatty foods, nature again provides an elaborated supply. The fat-splitting process is difficult in infancy and, consequently, the finer the emulsion of the fat in the milk, the more readily is its absorption effected. And in this quality milk varies. Much of the details of infant digestion remain to be determined. Some suggestions, offered by experiment upon the young of the lower animals, await confirmation. Nevertheless, these physiologic problems of infant digestion and maternal supply have been sufficiently worked out to afford the basis for a scientific substitution of human milk by artificial food in that great multitude of cases which demand a foreign supply. Into its consideration enter three primary factors.

1. Substitution must be effective in respect to *quality*. Food analysis has reached a point of accuracy which justifies the demand that food selection and food preparation for infant uses shall be essentially scientific. The market, full of manufactured infant foods, exploited in the secular and medical press as perfect substitutes for human milk and employed, upon hearsay, one after another, in the feeding of the mal-nourished babe, without so much as a personal inquiry upon the part of the prescriber into their nutritive qualities or mechanical conditions, is a scandal to the medical profession. The adulteration of infant foods with these products and the crude methods of modifying animal milk, without reference to the age and digestive powers of the infant-consumer, are curious persistencies of practice quite out of date with the general scientific progress of medicine. Substitution in respect to quality may be effected (a) by the modification of animal milk, (b) by its pre-digestion, or (c) by the use of manufactured foods. A comparison of these methods in detail is unnecessary. It is enough to express the belief that with the attainment of the scientific imitation of the human supply, for all periods of early infancy, by means of modified and pure animal milk, through such agencies as the Walker-Gordon laboratories, which sooner or later our towns and cities must support, will come the survival of our need either for manufactured foods or for the agents of pre-digestion. Only by laboratory methods can scientific modification and absolute purity be attained.

2. Substitution must be effective in respect to *quantity*. A working standard of quantities may be secured by the study of average infantile stomach capacities, at successive ages, compared with the average breast yield at such periods. The following table is illustrative, is accurate enough for guidance, and indicates that the average infant receives a large excess of artificial food.

PERIOD.	QUANTITY.
One week	70 c.c.
One month	95 "
Two months	140 "
Three months	170 "
Five months	215 "
Seven months	265 "
Nine months	300 "

While these average quantities are far less than most bottle-fed babies ingest, the writer can not endorse the contention of Dr. Rotch and others that over-feeding, in the matter of quantity, is a common cause of dilatation of the stomach. It may be doubted, indeed, if gastric dilatation is ever due to over-distension. It is rather the result of a loss of that muscular tone, of that obscure quality of tonic contraction which is the incident of the rest-period in the functional history of the stomach. This loss usually results from disordered chemic conditions within the viscus, due to the indigestion and retention of food. It has been induced, alike in men and in animals, by the repeated introduction of chemic irritants.

Fortunately, the infant stomach, both by its powers of rapid absorption and of ready emesis, resists over-distension. Moreover, distension is the natural precursor of peristalsis. It must be carried to a great excess before contraction fails of response. Excess of food quantity is a sufficiently certain cause of indigestion and of consequent malnutrition, without laying at its door problematic ills.

3. A third and most important factor in scientific food substitution is the element of *time*. Excessive feeding is the head and front of our offending against infancy, but excess is most customary in the practice of the people and of the profession at large, is most habitual in individual cases and is most destructive of infant life in the form of over-frequency of feeding. In its prevalence and in its dangers this practice is so pernicious that, beside it, excess in the mere matter of food quantity is of insignificant proportions. The period as well as the process of digestion is involved in this consideration. Error has grown out of the misconception that the term of digestion is to be measured by the length of time during which food remains in the stomach. In the infant it is peculiarly true that the gastric changes are but preliminary to intestinal digestion. The entire event, including the process of absorption, should be estimated and the physiologic rule of alternating periods of activity and repose in the digestive tract should be respected.

Human milk probably undergoes complete digestion in three hours. The best imitations of it require a longer time. The absorption of the products of digestion is not completed within this period.

In infancy, meal too often follows meal with so great rapidity that functional rest is altogether abolished. Indigestion ensues. Malnutrition or hyper-nutrition, which is practically the same thing, follows. A soil is cultivated in the food passages which affords good seeding-ground for pathogenic bacteria. The gastro-intestinal diseases of infancy, with their remarkable mortality, result.

In the past fifteen years clinical observation and physiologic study of this question have combined to mold, for the writer, a practice in this regard which has afforded overwhelming evidence that not even secondary in importance to the choice of infant food and of far greater consequence than the regulation of quantity, is the establishment of definite and, judged by common custom, of extremely infrequent hours of infant feeding. In nearly four hundred infants, fed upon human milk or upon carefully selected and modified artificial food, allotted to them in quantities corresponding to the physiologic standard given, and fed to them from *three to five times in the twenty-four hours*, according to the character of the food ingested, he has witnessed an attainment of weight and height, at successive

ages, far in excess of the average; he has seen the disappearance of serious gastro-intestinal disease and has recorded a mortality of but .75 per cent.

To the application of physiologic principles of infant dietary, rather than to the therapeutics of infancy, the profession must look for a diminution of infant disease and a conquest over infant death.

DISCUSSION.

Dr. C. B. VAN ZANT, Denver, Colo.—If the Doctor will permit I would like to add a fourth factor to the three he has so strongly presented—the matter of locality. With the quantity and quality of food and the intervals of feeding exactly the same, it is a notable fact that in different places the results of infantile feeding will be very different. It is one thing to raise a child artificially in the country and another in the city. Likewise differences will be apparent in different cities, much depending on external conditions. For a number of years I practiced in a crowded Eastern city; later on, in Denver. I am quite confident, as a result of observation, that infantile feeding is a much simpler problem in Colorado than in certain other sections and that gastro-intestinal disorders in infants, bottle fed, are much less prevalent and much less fatal here than in the East. I am not able to explain this satisfactorily, but venture the following points as probably important: (a) an unusually good and pure milk-supply in Colorado; (b) the common, out-door life and (c) the greater freedom from micro-organisms productive of fermentative changes in foods.

ABSORPTION VS. DIGESTION OF MILK.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY L. DUNCAN BULKLEY, A.M., M.D.

Physician to the New York Skin and Cancer Hospital; Consulting Physician to the New York Hospital, etc.
NEW YORK CITY.

No words or argument are necessary to show the advantage of milk as a nutriment. Millions of human beings, from the cradle to the grave, have proved its life-giving powers, and untold millions will continue to use it, wholly ignorant of any physiologic facts concerning its mode of influencing nutrition, and guided only by instinct, which in animals is unerring, but which in man is often perverted by the elements of civilization.

Milk is food. Alone and unassisted it is capable not only of sustaining life for an indefinite period, but it furnishes all the elements for the complete construction of the human frame; on it alone the infant learns to talk and walk, and develops all the tissues of the system. Adults have lived on it alone for weeks or months, and by it convalescents from grave sicknesses have recovered vitality and strength. Milk is a complex and delicate substance. While composed very largely of water—87 per cent. in an average good specimen—the remaining 13 per cent. contains a variety of substances wonderfully united, chemically and mechanically, in a manner suitable for absorption and appropriation by the economy. It is not the purpose of this paper to discuss the value of milk as a nutriment, nor to study its composition or chemistry, but only to present fully a practical theory in regard to the physiology of its *absorption*, under proper circumstances, as opposed to the commonly received notion that it must undergo *digestion* before it is assimilated in the system; and to this we will immediately proceed.

Some years ago a number of observers reported the intravenous injection of milk. It is not necessary here to recount the experiments and experiences, suffice to say that reliable men have succeeded in introducing pure milk directly into the veins of patients,

where it has mingled with the blood, going first to the lungs, without any thought of digestion, such as takes place in the alimentary canal. These patients lived and thrived under the process.

This intravenous injection and assimilation of milk-food first called the writer's attention to the fact that milk could be thus appropriated by the system without digestion, and led to the study and development of the theory to be propounded, and which he has put in practical application for ten or fifteen years, in hundreds and perhaps thousands of cases, and which daily experience confirms in a most substantial manner. I may say that the theory has been partially presented from time to time before medical societies and to friends, and also casually mentioned in writing; and while objections have been raised, these have generally been satisfactorily met and the plan proposed has been adopted successfully by very many, who, I am sure, would gladly bear witness if they were present. I may mention that the late Drs Marion Sims and Frank Hamilton accepted the theory and acted on it during the later years of their lives, and that the late physiologist, Dr. John C. Dalton, entirely acquiesced in its correctness, and Dr. Wesley Mills, professor of physiology at McGill University, Montreal, lately acknowledged the truth of the proposition.

Recognizing that milk could enter the system without passing through stomach digestion, I began to consider under what physiologic conditions this could be effected other than by intravenous injection. An analogy to the absorption of milk was found in the chyle and its discharge into the venous blood in the subclavian vein and vena cava on its way to the pulmonary circulation. When examined microscopically the chyle is hardly to be distinguished from rich milk, and it was argued that the milk globules could pass unchanged by the same channels through which the elements of the chyle were absorbed from the stomach and intestines; the problem was to present the milk in such a manner to the absorbents that it could be taken up immediately without having it undergo the process of coagulation, caseation and subsequent gastric digestion. Remembering that the blood was alkaline, the chyle alkaline, and normal milk also alkaline, it was suggested that if the milk could be presented to the absorbents in an alkaline state, and at a proper temperature, absorption might take place immediately without the intermediate process of digestion.

The activity of the stomach is such, as shown by the well-known experiments of Alexis St. Martin and others, that with the least excitation gastric juice is immediately poured out, which would, of course, at once coagulate some portion of the milk, and from this it would continue until all the milk was attacked, coagulated and digested. The problem was, therefore, to introduce the milk in such a manner that there should be no stomach activity and no secretion of gastric juice. Plainly then, it must be given quite apart from all solid food, or any substance or condition which could excite gastric juice. Even the least amount of acidity from a preceding meal would coagulate some of the milk and so start on the whole process of caseation and digestion.

Physiologically it is well recognized that the stomach in health does not ordinarily secrete gastric juice except under the stimulus of food. At a varying period after the taking of food, the time being dependent upon the amount and quality of the food taken and the powers of digestion, the stomach has finished its task,

absorption of certain elements has taken place, some portions have been passed on to the intestine, for further action, and the stomach is found to be empty, awaiting further cause for activity. At this period the stomach loses its turgid red color, becomes paler and more or less flaccid, and its surface is bathed with more or less of an alkaline secretion, this constituting the alkaline tide. As stated, this occurs at varying periods of time after the ingestion of food; it may occur in an hour or so after a very small amount of very digestible food, or not for four, five, or even many more hours after a very heavy or unusually indigestible meal, or with very weak or sluggish digestion. This should constantly be borne in mind in connection with the plan of treatment to be proposed, otherwise failure is sure to result. It is only when this alkaline tide is perfectly secured and utilized that the real beneficial results of this plan can be secured.

The idea, then, is to introduce the milk, pure and alone, and at the body temperature, just after this alkaline tide has set in, or during its continuance, and to avoid food or any substance which could call forth gastric secretion until after its absorption has been fully accomplished. It is believed, then, that the warm alkaline milk is absorbed directly by the lacteals and carried at once by the thoracic duct into the subclavian vein, and so reaches the blood and is acted upon in the lungs before it is submitted to liver action.

In contrast to this stands the physiologic process which takes place when the milk is taken with other food and submitted to ordinary gastric and intestinal digestion. Here after being acted upon by the gastric and intestinal juices its casein passes through the state of proteose into peptone and thence through the portal circulation into the liver, to be transformed into urea.

It is difficult to present absolute physiologic proof of the mode of *absorption* of milk here claimed, as opposed to its *digestion*, under the circumstances detailed, but strongly corroborative evidence is furnished in some experiments made by Dr. Andrew H. Smith of New York, who has kindly consented to my mentioning them. Some years ago, while experimenting on kittens to determine certain facts in regard to blood pressure, he accidentally wounded the jugular vein. To his surprise, the blood from it appeared of a lighter color than expected, and in marked contrast to that obtained from the saphenous vein. Taking another kitten from the mother's breasts he opened the jugular vein and found the same condition, and, I believe, he did the same with a third nursing kitten. He says that he could never explain the phenomenon until I propounded to him the theory of milk absorption, in full, which he at once accepted and regarded as an explanation of the condition found in the kittens; the milk being absorbed at once by the lacteals was poured by the thoracic duct into the subclavian vein and found ready exit on the opening of the jugular. I remarked to him that he had supplied the one missing link in support of my theory. It would be interesting to test the condition of the stomach, after taking milk on this plan, by means of the stomach-tube, but possibly this procedure might of itself excite gastric activity, which would confuse matters and vitiate the value of the experiment.

It would lead us too far from the practical object of this paper to attempt to enter at all fully into the

physiology of digestion and assimilation or to elaborate any of the physiologic chemistry of the subject. Suffice to say that this difference in the course which milk can take under varying circumstances becomes clearly evident, clinically and practically, with close and sufficient observation. Proof could be furnished by hundreds of cases in which the present writer has carefully directed this plan of taking milk and has observed and recorded the facts. Constantly those who have been quite unable to use milk in the ordinary way, have followed the plan proposed, with the most satisfactory results. In the writer's own person, milk taken in the ordinary manner and with food invariably disagrees, causing sick headache and functional liver disturbances, whereas, following the plan proposed, he has taken a quart of milk daily for ten and more years with the greatest benefit.

A few words may be added in regard to the practical features of the subject. It has constantly happened to the writer that patients have returned, after full directions had been given, as was believed, with the statement that the plan was not successful, and that it was impossible for them to take milk, as had always been the case. In some instances undoubtedly there may be such an aversion to milk, or such an idiosyncrasy in the patient, that even this plan does not succeed. But almost invariably it has been found that the want of success was due to some failure in carrying out the plan proposed; for it must be clearly understood and most strongly and forcibly declared that unless the theory is perfectly acted upon and the plan absolutely carried out as to all its details, the results claimed can not be expected. But after an experience with it of ten or fifteen years, and with the most varied and often difficult class of patients, and with many temporary failures, I again assert that when perfectly carried out results can be obtained which are of the greatest and most lasting benefit; there is hardly a single fact in medicine or feature in therapeutics of which I am more confident. It is sometimes difficult, however, to succeed at first in getting patients to carry out the plan exactly, for it must be remembered that the smallest possible amount of gastric juice or acidity will cause some portion of the milk to be coagulated; and when this digestive process is once begun, even in the slightest degree, it must go on until all the milk has been attacked and digested.

In many instances I have found that patients had taken with the milk a small amount of food, as a cracker, following the advice of a former physician or that of friends. Again, some will put an egg in the milk, or add whisky or brandy, and in many ways I have had the correct operation of the plan interfered with. It repeatedly happens that the milk is taken too soon after a meal, or perhaps even when a long enough interval of time has elapsed, it has happened that owing to a sluggish digestion, it has come upon the products of a former meal, and not during the alkaline tide. Thus, patients will often take milk at half-past ten or eleven in the morning or at three or four in the afternoon, because at that time they had felt a faint and "gone feeling" and mistook the uncomfortable sensation of delayed digestion for hunger. It will, therefore, often be very difficult to be sure that the stomach has reached the alkaline condition, when only the milk can be taken with advantage. My rule is not to have it taken longer than an hour before the coming meal, but under proper conditions it may often be taken

even up to thirty minutes before eating, although this is rare.

Sometimes, if the digestion is sluggish, it is necessary to administer pepsin or other digestives very freely and repeatedly, to secure an empty stomach early enough; and at times when there is any doubt, I have taken one or more doses of bicarbonate of soda half an hour or so before taking the milk. It is also often advantageous to put a little bicarbonate of soda into the milk, if there is any question as to its perfect alkalinity or as to the alkaline state of the stomach. But these measures will not be successful if there is food or any remains of an acid digestion.

The temperature of the milk is also an element of importance. If taken iced cold the perfect action of the plan is frequently interfered with; the effort to warm the milk in the stomach, which is necessary before absorption, will often seem to give occasion for an attempt at stomach digestion, and a sensation of pressure and discomfort will follow, which is far different from the agreeable sensations accompanying its proper use. My directions, therefore, are that the milk shall be made of the body temperature, by heating it carefully in hot water, if possible; if boiled so as to produce the slightest scum on the surface, and this is taken, it acts prejudicially by exciting gastric action, and the aim of the process is defeated. It is often desirable to warm the milk by the addition of hot water, as absorption is even more readily affected thus than when the milk is too rich and thick.

I have also often seen harm done when cream had risen, and had been stirred into the milk, forming flakes; these small solid particles being incapable of immediate absorption may result in causing the secretion of gastric or pancreatic fluid in the process of digestion.

Many of these points—and more could be mentioned—may seem trivial and unnecessary, but long experience in following the plan proposed under the most diverse circumstances has convinced me that in this, as in so many other medical matters, attention to details is of the utmost importance; and, as reiterated here more than once, it is essential that the plan be perfectly followed in every detail, in order to obtain perfect success.

When prescribing milk according to the plan proposed, pure, warm and alone, one hour before meals, patients often object that it would destroy what appetite they have. But it is an interesting fact, based on physiologic reasons, that when thus taken successfully it not only does not impair the appetite, but greatly increases it. If a particle of food, as a cracker, is taken with it, or if for some reason or fault it does not act exactly rightly, then the appetite is impaired; naturally so, because there is a process of digestion which takes a longer time than the hour, or rather half hour required for its absorption, and the stomach can not be ready for fresh food again so soon.

The physiologic basis for the improvement of the appetite is simple. The process of secretion from the glands of the stomach and elsewhere, depends largely upon osmosis and blood pressure. By the quick absorption of milk the pressure of the blood in the capillaries is increased, and a richer blood is offered for the secretion of the gastric juice. This improvement in the appetite under this plan of treatment has been observed by myself and others in dozens of instances.

A common time of administering milk with me,

especially in poorly nourished females, is in the morning, one hour before breakfast, the directions being that the patient shall lie still for a quarter of an hour thereafter; it is often found then that instead of rising fatigued, with no appetite for breakfast, the patient gains in strength and enters on the day with a vigor quite unknown before. I also very commonly have weak females lie down in a darkened room for a half-hour nap after taking the milk at 12 and 5 o'clock. I could give many, many instances where the transformation of the patient by this simple procedure has been really marvelous. The soporific qualities of warm milk at bedtime or in the night are sometimes remarkable.

I trust I may be pardoned for my seeming enthusiasm in regard to the plan proposed, for it is presented after mature thought and very extensive experience, dating back many years; and I only wish to make this theory and plan so clear and plain that many may be led to adopt it in daily practice, feeling sure that if properly understood and faithfully carried out their experience will be the same as mine and that of many other physicians who have accepted and worked upon it.

4 East Thirty-seventh Street.

DISCUSSION.

Dr. ROBERT H. BABCOCK, Chicago—I desire to add my testimonial to the efficacy of milk taken in accordance with Dr. Bulkley's method. Since having learned of this way of drinking milk two years ago, I have so prescribed it to many patients, and with but one exception, I think, they have experienced no difficulty in its assimilation. On the contrary, it has been well borne, and, what was almost incredible to me at first, it has been found not to interfere with appetite for, and digestion of, the following meal. I am at a loss to explain why milk taken in this manner should agree better and apparently be absorbed or assimilated differently from when drunk at meal-time, but I am convinced that some difference does exist. So firmly rooted are the teachings of physiology in my mind that I am not able to accept Dr. Bulkley's explanation of its absorption directly, as unaltered milk. It may be that being bland and warm the milk is allowed by the empty stomach to pass through into the duodenum; but how it can escape the action of the milk-curdling ferment of the pancreatic secretion, I can not understand. Of course, the cream, or fat of the milk can be taken up by the lacteals at once, since it is already in a state of fine emulsion, while the water and the salts in solution might be quickly and directly absorbed; but I confess I can not understand, as yet, what is done with the casein if it is not subjected to digestion in the small intestine. However, my failure to understand the mechanism of its digestion, or absorption without digestion, offers no barrier to my acceptance of its clinical value when taken in the manner devised by the distinguished author of the paper.

Dr. H. W. SCAIFE, Chicago—My objection to Dr. Bulkley's theory is this: He asks us to believe milk is absorbed by the lacteals as water would be by a sponge, and is conveyed to the veins unchanged. His theory is entirely groundless; his idea of assimilation old-fashioned. The walls of the intestines do not act like inanimate membrane. "The act of seizing food," says Binet, "belongs to living tissue. It is not a chemic nor a physico chemic, but a physiologic phenomena." So it is entirely inadmissible, that by his method of administration or any other method, milk can pass through the living tissue without change. His clinical facts are good, his theory to explain which is entirely false, and if he injects milk into the veins of any animal, he will not feed it, but kill it.

Dr. C. B. VAN ZANT, Denver—Dr. Bulkley's paper, based as it is, upon such a large amount of clinical experience, the value of the method which Dr. Bulkley advocates, can not be gainsaid. With his theoretic explanation, however, of the physiology of this process we must heartily disagree. It is contrary to all the present teachings of physiology to suppose that milk can gain access to the blood-current unchanged and without previous coagulation and digestion. In the first place, we can not believe that milk in any form, or temperature, or in any manner of administration will fail to evoke an outpouring of gastric juice. The experiments of Beaumont showed that it invariably follows the ingestion of fluids, and even the gentlest

titillation of the gastric mucous membrane led to its discharge. If this be true, coagulation of the milk in the stomach is certain, no matter when or how the milk be given. If, however, we grant the possibility of the milk running the gauntlet of gastric juice coagulation and a partial digestion, what assurance have we that it would fail to excite the pancreatic secretion, by which it would inevitably be coagulated and digested? It seems to me totally untenable to suppose that the milk can enter the absorbents directly and without change. While I gladly admit that the method of milk administration which Dr. Bulkley advocates seems to have the weight of clinical experience back of it and to be valuable, the theory as to its action seems to me out of accord with the present accepted beliefs of the best physiologists.

Dr. BULKLEY, in closing, said he was glad of the criticisms which had been made, as he believed that only by frank and full discussion could truth be brought out. He had purposely presented the paper before the Section on Physiology because he wanted the theory proposed to be scientifically considered and criticised, and he should endeavor to benefit by the remarks made, and should study the subject still further.

But he would say that in spite of the objections that had been raised he should still adhere to theory as proposed until a better working hypothesis was obtained. Because, however the ultimate course of the milk may be considered physiologically, there was somehow a vast difference, greater than he could express by words, between the behaviour of milk when taken in the ordinary way carelessly, or with food, and when administered absolutely according to the principles and methods laid down. This clinical difference, which he had observed for many years—from ten to twenty—and in hundreds of instances, must have some scientific reason back of it; and, for his part, he would prefer to accept the accumulated evidence of years as demonstrating some physiologic difference than accept the statements or arguments that had been brought forward to show that the theory was untenable. Possibly the physiology was wrong—for this is a somewhat changing science—and we can not explain just how milk or indeed other aliments act under perfectly normal conditions, for it is to be remembered that experiments, on which physiology is based, always introduce an abnormal element themselves. He should, therefore, adhere to his theory as an excellent working basis, because it furnished the means of aiding in carrying out intelligently the system or plan described, which with him and others had yielded such exceptionally beneficial results.

WHAT IS THE FOOD VALUE OF ALCOHOL?

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY E. STUVER, M.Sc., M.D., Ph.D.

Member Colorado State Medical Society (Vice-President 1894); Rocky Mountain Inter-State Medical Association; American Medical Association; International Medical Congress, etc.

RAWLINS, WYO.

Food is described by the Standard Dictionary as: "That which is eaten or drunk, for nourishment, aliment; nutriment in the scientific sense; any substance that being taken into the body of animal or plant, serves through organic action to build up normal structure or supply the waste of tissue, nutriment; aliment as distinguished from condiment;" and Webster gives substantially the same definition.

While these definitions give what I desire to designate as the positive side of the question, there is also a negative side which should be considered in arriving at a true estimate of the food value of any substance ingested by man or animals for the purpose of nutrition. By this negative side I mean that the food substance, while containing the elements necessary for tissue-building or heat-production, should not interfere with the normal organic processes of digestion, assimilation or excretion. Nor should it interfere with the normal oxygen-carrying power of the red-blood corpuscles or impair the healthy activity of the enveloping membrane which surrounds all the tissues and cells of the body, and on whose unimpaired dialyzing power the *endosmosis* of nutrient

material and the *exosmosis* of broken-down, retrograde products or toxins depend. As you are all well aware, recent investigations have demonstrated the immense importance of auto-intoxication and the very serious consequences that may result from retained toxins or waste materials. On this subject Dr. Thomas Oliver speaks as follows: "Bouchard" clearly indicates to us that man is constantly standing, as it were, on the brink of a precipice; he is continually on the threshold of disease. Every moment of his life he runs the risk of being overpowered by poisons generated within his system. Self-poisoning is only prevented by the activity of the excretory organs, chiefly the kidneys, and by the watchfulness of the liver, which acts the part of a sentinel to the materials brought to it by the portal vein from the alimentary canal.

In view of these facts free elimination assumes a very important place and must receive careful consideration in arriving at conclusions concerning the relative value of nutrient materials. We should inquire, not only as to the tissue-forming or heat-producing power of any particular food substance, but also ascertain how it affects digestion, assimilation and excretion, and then we will be in a position to arrive at a true estimate of its value to the system. On this basis, let us now try to ascertain the food value of alcohol. I shall confine what I have to say to ethylic alcohol (C_2H_5HO), the kind in common use.

Ever since the earliest historic times until within recent years, it has been believed that alcohol is a true tonic; that it stimulates mental activity, increases muscular force and the powers of endurance; that it enables man better to endure the rigors of extreme cold and the fervor of intense heat than he could without it; that it protects him against the invasions of disease and helps him to counteract their effects and throw them off when contracted—in short, that it elevates his thoughts, increases his powers, blunts his pains and sorrows and enhances his joys. Even twelve or fifteen years ago it was believed by many eminent authorities that pure alcohol possesses a positive food value. T. Cranstoun Charles² says: "As to the rôle played by alcohol in the economy there is still some difference of opinion, but the weight of evidence is in favor of the theory that it acts more or less as an aliment. When ingested in excess much of it traverses the system unburnt and is then found in the urine, sweat and expired air (Lallemand, Perrin, etc.); but when taken in a moderate dose the amount eliminated by the urine forms but a small proportion of that absorbed (Dupré); some even maintain that the quantity thus excreted does not amount to more than 0.7 per cent. (Thresh). The chief portion of the alcohol in the latter case, therefore, undergoes consumption in the body (Anstie, Thudicum, Schullimus, Baudet, etc.). We shall see elsewhere that a little alcohol is generated in the organism itself (Bechamp). Alcohol does not appear to increase the production of heat as a chemic agent (E. Smith), rather, in large amount, lowering temperature by checking some of the oxidation occurring in the body, particularly when abnormal, as in fevers. It also, when given in a state of health, tends to diminish muscular power, but indirectly the effect may be to increase it by improving the tone of the system

¹ Bouchard: Preface to "Auto-Intoxication in Disease," page 8.

² Elements of Physiologic and Pathologic Chemistry, 1884.

through the appetite and digestion of food. While the carbonic acid exhaled is slightly diminished when wines and beer are taken in moderate quantity, the secretion of gastric and pancreatic juices is favored, and there is a gentle excitation of the nerve centers, and at the same time an undoubted addition made in the form of salts, fats, glycerin and albuminoids—beer being not only stimulating and tonic, but also nutritious. Indeed, of the alcoholic drinks beers occupy the first place as foods; then come cider and perry, then wines, and as they sustain and increase vital action, they must be regarded as true foods (E. Smith). According to Voit, also, alcohol must be regarded as a food, as under its influence fewer substances are decomposed in the body."

"Considered dietetically," says Pereira,³ "beer possesses a threefold property: it quenches thirst, it stimulates, cheers, and if taken in sufficient quantity, intoxicates; and lastly, it nourishes and strengthens. The power of quenching thirst depends on the aqueous ingredient which it contains, assisted somewhat by its acidulous constituents (carbonic and acetic acids), its stimulating, cheering or intoxicating power is derived either wholly or principally from the alcohol which it contains (2 or 3 per cent.—in some stronger, 5 to 7, and exceptionally 10 per cent.); lastly, its nutritive or strengthening quality is derived from sugar, dextrin and similar substances contained in it; moreover, the bitter principle of hops confers on beer tonic properties. From these combined qualities beer proves a refreshing and salubrious drink if taken in (scrupulous) moderation, and an agreeable and valuable stimulus and support to those who have to undergo much bodily fatigue."

The above quotations are given because they tersely show the opinions held by many leading physicians fifteen years ago as to the tonic and nutritive properties of alcoholic beverages. As you have doubtless perceived, however, the statements are very vague and general, and when closely scrutinized it will be observed that those beverages for which the greatest thirst-quenching, tonic and nutritive properties are claimed are the ones which contain the smallest percentage of alcohol. This fact in itself should create the suspicion that the opinions expressed were influenced to a certain extent by inherited or acquired appetites or cravings, preconceived opinions or in extenuation of existing habits.

Let us now glance at the physiologic effects of pure ethylic alcohol as determined by careful, accurate and painstaking investigations, with the aid of modern scientific instruments of precision. It is generally conceded that alcohol is almost immediately absorbed into the blood. Here it exerts a most pernicious effect on the red-blood corpuscles, dissolving their iron and devitalizing them (Dr. Wm. Hargreaves), arresting their development and hastening their decay (Drs. Virchow and Becker), as well as diminishing their oxygen-carrying capacity by lessening their power to absorb oxygen from the air in the lungs; by its strong affinity for water it absorbs a part of their moisture, causes them to shrink, harden and may even make them adhere in masses and so hinder their passage through the tiny capillaries (Dr. B. W. Richardson). While in the stomach, instead of aiding digestion, as was formerly supposed, it has been shown by many careful observers that alcohol in very small amount actually retards the

digestion, especially of proteids, very much. This retardation reduces the amount of nutrient pabulum to be taken up by the blood, whose functional or selective activity as we have before seen is likewise impaired by the alcohol directly absorbed. Nor do the evils end here, because the alcohol contained in the circulating fluids on coming in contact with the enveloping membranous sheaths which surround all the tissues and cells of the body, coagulates the albumin contained in their secretions, forming a thin white film over their surfaces, thereby impairing their dialyzing power and interfering with the free ingress of nutrient material for the upbuilding and renovation of the tissues and cells as well as obstructing the free egress of retrograde products or toxins on whose prompt elimination and destruction the healthy activity of the body depends.

With the digestion retarded, the oxygen-carrying capacity of the blood lessened and the assimilation of nutrient materials as well as the elimination of retrograde products and toxins greatly impaired by the clogging of the dialyzing membranes, we would logically infer that alcohol exerts a pernicious influence on the development and functional activity of the muscular and nervous systems, besides perverting and impairing the special senses and mental activity of those who use it (effects diametrically the opposite of those produced by true foods!), and this inference or conclusion we find fully sustained by incontrovertible facts. As cogently stated by Dr. Bunge: "Thousands of experiments on large bodies of men have been made and have led to the result that, in peace or war, in every climate, in heat or cold and rain, soldiers are better able to endure the fatigues of the most exhausting marches when they are not allowed any alcohol. A similar result is observed in the case of the navies, and on thousands of commercial vessels belonging to England and America, which put to sea without a drop of alcohol. Most whalers are manned by total abstainers." Arctic explorers endure the severe cold much better when they abstain from alcohol than when they use it, even in moderation. Nor is this knowledge confined to physicians and physiologists, but the great business interests of the country are beginning so thoroughly to appreciate the fact that alcohol unfits men for doing the best work that many railroads and large manufacturing and mercantile establishments will neither employ nor retain in their employment persons addicted to the use of alcoholic beverages. That alcohol lowers muscular force and endurance is very conclusively shown by the fact that those who engage in athletic sports must stop drinking if they expect to excel. No prize fighter, ball player, oarsman or any kind of athlete can keep up drinking habits without so injuring himself in a few years that he is relegated to the rear as a back number. The careful experiments made on a number of persons by Dr. J. H. Kellogg, several years ago, showed that muscular strength is diminished more than 30 per cent. by the use of alcohol, and substantially the same conclusions were reached by the elaborate experiments of Prof. C. F. Hodge, on dogs, as detailed in the *Popular Science Monthly* of March and April, 1897.

EFFECTS ON THE NERVOUS SYSTEM.

But while alcohol retards digestion, impedes assimilation and excretion, reduces the oxygen-carrying power of the blood and inhibits the nutrition of the

³ *Columbian Encyclopedia*, Vol. xii.

cells and tissues of the whole body, still it is on the brain, or indeed the whole nervous system, that its most far-reaching and malign influences are exerted.

The preliminary stimulation accelerates the heart's action, thereby increasing the amount of arterial blood sent to the brain. This produces the stage of exhilaration, excitement, brilliancy and sometimes frenzy and delirium.

"Owing to the loss of contractile power of the vessels, the increased blood-supply can not be returned to the veins from the brain with sufficient rapidity, and thus there is a block, causing impediment of the circulation, which ought to be free and unimpeded, to allow duly aerated fresh arterial supplies. This is the stage of depression, of depression and collapse, when the memory fades, speech is thickened, voluntary movement ceases, sensation is dulled and consciousness fails. This process frequently repeated sets up permanent tissue changes. The covering envelope is so thickened and otherwise injured that proper nutriment can not be conveyed to the brain, and thus that organ is badly nourished. The shape of the brain cells is altered, and the physical degradation of the cerebral substance sadly impairs the intellectual and moral faculties." (Dr. Norman Kerr.)

I believe the correctness of this picture can be vouched for by nearly every physician. Indeed, good illustrations of it are constantly seen, sometimes even at medical banquets. Nor is this all, for under the influence of alcohol the brain begins to think awry. It can not think straight (Dr M. S. Holbrook), and its influence on psychic processes is curious, for while it renders them much slower, the individual under its influence believes them to be much quicker than usual (Dr. Lauder Brunton). Indeed, experiments made in Heidelberg University show that the consumption of alcohol, whether in large or small doses, produces a tendency to paralysis of the mental faculties (Dr. Adolph Barr).

In view of these facts, I am led to believe that the so-called tonic or strengthening effects of alcohol are due more to its anesthetic and paralyzing power than to any true nutritive or tonic properties it may possess. As Dr. Kellogg has very felicitously said, alcohol is a "*nerve-fooler*." It makes the person who indulges in it believe his condition is very different from what it really is. If he gorges himself with too much food, alcohol may quiet the protests of his digestive organs and paralyze him into the belief that it is aiding his digestion and increasing his strength, whereas it is doing nothing of the kind.

While he may believe that his senses are keener and his powers of endurance greater, experiments with scientific instruments of precision have demonstrated that his acuity of vision is lowered, his power of hearing reduced, his sense of smell blunted and his taste so obtunded that he can swallow fiery and even caustic liquids without wincing, and his muscular strength, which he believes to be greatly augmented, is shown by the dynamometer to be materially reduced, and even his soul-stirring eloquence and poetic flights are largely discounted in the estimation of the man who has not been imbibing.

Since alcohol thus deceives the person who uses it, and as most of the beneficial results claimed to arise from its use are based on the subjective sensations of those using it, I believe we are justified, after a careful consideration of all phases of the question, after examining the arguments for and against and apply-

ing to alcohol the same tests that we use in determining the utility of other substances used as food, in concluding that if it possesses any food value at all, it is to a very limited extent, and that the dangers connected with its use are so great and far-reaching that it, as every other narcotic poison, should only be used after the greatest possible precautions have been taken to guard against its untoward effects.

DISCUSSION.

Dr. STUVER, in closing the discussion—I do not wish to be understood as claiming that alcohol does not have any food value. The point on which I wish to insist is, that in view of the great possibilities of doing harm, every case should be carefully investigated, and alcohol should not be prescribed in any form unless we are fully satisfied that its dangers and disadvantages will be more than compensated by its good effects in the patient's case. In short, alcohol should be used with as much care as morphin, strychnin or any other poison, and not in the careless, indiscriminate manner in which it has been in the past.

ALCOHOL IN HEALTH AND DISEASE.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY V. D. MILLER, M.D.

NEEDHAM, MASS.

It is with some hesitancy that I present this subject for your consideration, knowing, as I do, the extreme differences of opinion in regard to the effects of alcohol upon the human system, especially in disease. It is over sixty years since the composition of alcohol and its effects upon the human body have claimed the special attention of chemists, physiologists and philanthropists. Since this time very many investigations and observations have been made, and numerous important and scientific works written by investigators whose names stand high in the annals of chemistry and physiology.

Among the seventy-six known elements, there is one called carbon (chemical symbol C). This element is termed an organic substance, as it occurs abundantly in living matter; it is a waste product of animal and a reconstructive product of vegetable life—that is a food for plants and an effete matter of animals. The atomic weight of this element is 12, and its quantivalence is 1, 2, 3 or 4, making it twelve times as heavy as our standard—hydrogen (H). It may replace atom for atom, or 1 for 2, 3 or 4. Owing to its great latitude of power it unites very readily with hydrogen, nitrogen, oxygen, sulphur (H, N, O, S) and their radicals, forming a great number of chemic compounds, among which are many of the new therapeutic remedies. We also have sugar, fat, oils, ether, chloroform and alcohols.

In forming these different classes of compounds carbon follows out definite and fixed laws from which it does not vary. Through the decomposition of vegetable matter a gas is generated known as marsh gas (C_2H_6)—methane. To this gas add OH and you have an alcohol. There are many gases to which if you add OH alcohols are formed. The alcohol ($\text{C}_2\text{H}_5\text{OH}$)—ethyl alcohol—is the one used for medicinal purposes, and is one of the best solvents we have. It readily unites with gums and resins, dissolving them; it coagulates proteids, because of its eagerness to unite with water (H_2O), generating heat sufficient to cook the contained albumin. This is what takes place in the human tissues which contain albuminoid matter. The heat generated by contact of alcohol and living albuminous tissue first coagulates

the albumin and renders it unfit for chemic reaction.

Professor Hodge of Clark University says that alcohol retards, prevents and is destructive in either large or small doses to normal growth and development; it lowers the working power.

Dr. Chittenden of Yale University says amounts of alcohol equal to 5 per cent. are markedly injurious and retard digestion.

Drs. Zimmerburg of Germany and Marvaud of France by their experiments proved that small doses of alcohol increase the frequency of the pulse, that large doses increase at first, then diminish the heart's action; very large doses depress at first.

Professor Martin of Johns Hopkins University, in his demonstrations of alcohol on the action of the heart, says that an ounce of whisky or brandy always lessens the force of the heart, but generally increases its frequency. The habitual use of alcohol is certain to work a change in the muscular structure of the heart and arteries.

Dr. Woodbury of Philadelphia (Board of Health) says nothing in clinical medicine is more certain than that the continued use of alcohol stimulates the development of connective tissue all over the body, therefore it is a prolific source of disease.

G. Newton Pitt says 75 per cent. of the cases of alcoholic neuritis and 20 per cent. of cirrhosis of the liver was found on postmortem to have tubercular lesions; these lesions assume the fibroid form.

Dr. J. F. Pain of St. Thomas Hospital, London, says that one of the effects of alcohol is to produce an accumulation of fat in the liver. In speaking of its effects upon the nervous system he gives cases of paralysis of the phrenic and pneumogastric nerves, also changes in the peripheral nerves producing hyperesthesia, paresthesia, anesthesia, with loss of knee jerk at every stage, this symptom constituting the symptoms of alcoholic ataxia.

Dr. N. S. Davis says when alcohol is taken into the human stomach it is rapidly absorbed, carried directly into the blood, consequently it undergoes no digestion or assimilative change in the digestive organs and is not converted into elements capable of contributing to the growth or repair of the organized structure of the human body. It has been many times detected as alcohol unchanged in the blood, liver, brain, lungs, kidneys and all the other structures of the body.

Chemistry shows us that alcohol is not a tissue builder, containing none of the elements from which the tissues are made. Its use in health can not be of any value. It is true the grains from which it is made contain gluten, fibrin, etc.—elements of great importance in the development of the human system—but in the production of alcohol a chemic change is produced, so that there is nothing which the tissues of the body can appropriate to their use, consequently, from a physiologic standpoint, we are forced to admit that its use in health even in small doses is deleterious. Take, for example, a sensitive, intellectual young man, a specimen of anatomic and physiologic perfection, note the deleterious changes which the habitual use of alcohol has upon him. The blood becomes impure, as evidenced by the red nose, pimples and blotches on the face; his nervous system deranged, as evidenced by his coarse language, irritable disposition and high temper, often abusive to the mother to whom in former years he gave most reverential and respectful attention. To the wife, whom

he once adored and would have given his life to protect, he becomes cold, harsh and abusive, often treating her with contempt. The children, once his pride, he neglects or often robs, and to his best friends he even becomes insulting. Will some advocate of the "social glass" explain to us the physiologic and beneficial effects of alcohol upon the brain in this case? If alcohol is of no benefit, but decidedly deleterious in health, can we find a use for it in disease?

Dr. Samuel Wilks, F.R.S., consulting physician Guy's Hospital, London, says: "I found it necessary to withstand the use of alcohol in medicine at an early period of my practice. It lowers the functions, causes degeneration of the nerve centers and produces general paralysis, trembling lips, shaky hand, unsteady walk; muscles undergo a change; heart becomes fatty, nerves hardened and thickened from neuritis. Digestive organs morbid, loathing food. Ulceration, thickening of the walls of the stomach and intestinal tract."

In speaking of alcohol as a drug I do not hesitate to say that those who give it believing it to be a stimulant are totally mistaken in its action. In mitral disease of the heart it adds fuel to the fire. There was a time when brandy was the universal medicine in fever. At the present time its universality is abandoned. A number of medical men hold fast to the old notion that brandy supports. For my part, the reasons for giving it are erroneous. At present its employment by judicious men is almost ignored, and they are certainly better practitioners than those who give it to every patient who had a weak pulse. Our knowledge of the action of alcohol in disease is almost empiric, having so few principles to guide us. So far as my observation goes, those physicians who use it in typhoid fever and pneumonia lose a large per cent. of their cases, while those who treat these diseases without alcohol seldom lose a case.

The effect of alcohol is to stimulate the heart to increased action and increased circulation and respiration. In fever we have too rapid circulation and respiration with high temperature. Why, then, give something to increase this condition? Some of our best physicians with large experience, while noting the increased action of the heart from the use of alcohol, find that its force or power is diminished. May this not be the principal cause of the so-called heart failure which many practitioners give as the cause of death? Alcohol being chemically a hydrate, must, on physiologic principles, increase the heat of the system, which contraindicates its use in all fevers. Some physicians use alcohol in their practice because their preceptor or some writer used and recommended it; others because their mothers believed in and used it, and they, perhaps without being aware of it, inherited an affection for it. In fevers we have a variety of remedies which have a tendency to lower the temperature and shorten the disease, of far more value than alcohol. Our list of tonics (not stimulants) is numerous. With a chemic knowledge of the elements of food and their different combinations we can feed and care for our patient so that very little medicine will be required. Let us banish tradition and treat our patients upon common-sense principles, then we shall have little use for alcohol.

DISCUSSION.

Dr. C. B. VAN ZANT, Denver—The question as to the status of alcohol in health and disease is a large one, and one that is arousing the greatest attention throughout the country. Like

every other question it has its extremes and a happy mean. There can be no question that the pendulum is swinging away from the indiscriminate use of alcohol as practiced in former days. This is true in our own profession, as evidenced by the fact that a large number of our best men are earnest members of the American Medical Temperance Association, which stands for a restricted use of alcohol in disease. In my judgment, we ought to deal with alcohol as we would with morphia, recognizing that it is an agent both for good and evil. I have long accepted as a maxim the terse statement of Austin Flint, Jr., that "whenever a sufficient quantity of food, to meet all the needs of nutrition, can be taken and digested, alcohol is not only unnecessary but injurious." This statement applies both in health and disease. I think it is taking up an extreme position to say that alcohol never has a legitimate use either in health or disease, and in this respect the author's views fail to meet my own. In moderate quantities it is surely oxidized, and if oxidized, it must be a producer to some degree of animal heat and force. In disease, where a "sufficient quantity of food can not always be ingested and digested," the importance of the use of alcohol is apparent, as a temporary prop to the vitality of the patient. It is only in these temporary conditions that we find its highest value in disease. As an article of diet in health it is certainly unnecessary, if not immediately and tangibly injurious.

Dr. H. R. SLACK, Lagrange, Ga.—I regret exceedingly that the author of this paper is not present, for I would like to inquire whence the quotation of Dr. Martin was obtained. It was my good fortune to have studied under Professor Martin at the Johns Hopkins University, and he taught: "According to circumstances alcohol may be either a poison or useful; when useful it may be regarded either as a force-generator or a force-regulator. It is sometimes a valuable medicine, but does no good in a healthy body. Its proper use is as a whip, to stimulate the flagging energies, and it enables the physician to win many a race for life that otherwise might be lost." Dr. Osler recommends its use strongly in typhoid fever, and in pneumonia says: "It is the only remedy in many instances capable of tiding the patient over the dangerous period." There is no substance in the whole range of medicine concerning the uses and effects of which there is a greater diversity of opinion than alcohol, some as the writer, holding that these are wholly bad and that "no good thing can come out of Nazareth," while to others it is an ideal stimulant, tonic and food. I hold an intermediate position, one that I consider the golden mean, and the position of Dr. Martin as stated before. I have seen many cases where its beneficial effects were marked. It is a well-known fact that the mortality from typhoid fever in the London Temperance Hospital has for the last twenty years been 15 to 16 per cent.; much greater than in other hospitals where alcohol is used. I believe that at present we have no medicine in the pharmacopeia that can replace alcohol as a stimulant, and in some cases its use is necessary.

DIETETIC CAUSES OF INEBRIETY.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY T. D. CROTHERS, M.D.

SUPERINTENDENT WALNUT LODGE HOSPITAL,
HARTFORD, CONN.

Inebriety is one of the most complex neuroses and obscure border-land diseases known. To the average practitioner the inebriate is simply a weak, wilful, vicious man, who has full power to do different but will not exercise it. When the inebriate is examined carefully, and all the facts of his inheritance and of his nutritional, and also mental life and growth are grouped, a uniform progressive line of disease is found. The pathologic conditions which precede alcohol and the conditions which follow from the use of alcohol, are marked in different degrees. The former are not recognized and the latter only recently have come into prominence. The use of alcohol is followed by conditions which differ very widely, and are unexplainable except by a study of preceding conditions before spirits was used. One of these conditions is heredity, that is the transmission of defects and predispositions to degenerate in certain directions, with or without special exciting causes. Another is nutrition, a third

is disease and traumatism and its sequelæ, a fourth is culture and environment, and so on through a long list of causes. In all cases, it may be said that the nerve centers suffer from practical starvation, and the narcotism from alcohol is grateful in covering up the irritation and pain demands for help. In my studies the nutrition of childhood has been found to be an active cause in many cases. I have divided these into the *overfed* and *underfed* cases. In the former the clinical history would follow these general outlines: The nursing child would be surfeited both at the breast and by infant foods. The central thought of the parents would be the danger of starvation and the need of constant ingestion of food. When indigestion followed, another nurse and changed foods in equal quantities would be given. Later, when the child was able to occupy a place at the table with his parents, all discrimination was left to his own tastes, the parents reasoning that the appetite was the best guide and the child's food inclinations should be followed. Anything the child called for as foods or fluids were given freely. The disturbances of digestion which follow are usually treated as weaknesses and tendency to diseases. Consumption, rheumatism, disease of the liver, stomach and kidneys, and other formidable diseases are discerned in the horizon by the worldly-wise physician. Patent foods, climate cures, changes of school and culture and many remedies are tried. Finally puberty is passed, and the digestion is permanently impaired. The appetite is lawless and without control. The body is ill-nourished. Already fatty deposits have begun. The demand for foods and fluids are mere impulses. The taste is disordered. Large quantities of certain classes of foods are taken, then abandoned. The same of fluids, teas, coffees, mineral waters, beers, wines and anything used at the table.

Indigestion and obscure or well-defined nerve failures, nerve disturbances, irregularities of sleep all follow. Then finally comes the subtle tonic bitters containing from 20 to 40 per cent. of alcohol, or the wines or whisky, and inebriety has come. The relief which spirits brings is so marked that it is continued, and then follows a rapid, sharp degeneration, and the inebriety is chronic and complex mental and physical changes appear; opium and other narcotics follow, changing from one to another. This picture is not confined to children of wealthy persons, but occurs in all the various circles of society, in the families with moderate means, and occurs among children who are obliged to begin the serious work of life at an early age. The dietetic delusions of parents are engrafted and graven in the minds of children and the end is inebriety. Some of these cases take on paroxysmal forms, after spirits are used. Thus, an attack of acute indigestion is followed by a drink craze which after a certain time subsides, and breaks out again after a free interval. They become periodic drinkers, and when they die show in the postmortem remarkable stomach degenerations. It is found that the sudden, unreasoning outbreaks of what is called alcoholism, or the use of spirits to prolonged intoxication, occur in those delusional dyspeptics who, from infancy, have had no dietetic or food control. Such morbid eaters occur often among prominent men, and when they begin to use spirits they have no power of control and are soon pronounced inebriates. In these cases digestion is early strained and stimulated far beyond the needs of the body, and the food, non-

assimilable or in excess of the demands of the organism, accumulates and becomes sources of degeneration. Overgrowths, retarded growths, defective growths, with functional derangements both of physiologic and psychologic control follow. Excessive nutrition in childhood is a cause of inebriety in later life, both with and without special exposure, and often among persons who by environment would naturally not use spirits.

The second class of cases I have called the underfed. By that I mean persons who have been practically starved in many ways the first twenty years of their lives. The starvation has come from exclusive diets used from necessity or from theory, or from carelessness and neglect. In very poor families the food from infancy would be potatoes, corn meal or pork almost exclusively, or fruits in more tropic climates, in some form of liquid foods, no variety and one article almost exclusively. In other families, from theory, children would be forced to use one class of food and no others, as for instance meats, or grains, or fruits, to the exclusion of every other class of foods. In the larger proportion of cases, carelessness prevails. Children are supposed after the nursing period to eat the same foods as the rest of the family, and are given without discrimination anything which is prepared. No care is taken of their diet, no judgment is exercised as to quality, variety or nature of foods. At one time fruit is used to excess, or vegetables, or meats, or grains, according to the supply. In the family of a country grocer three boys, after a protracted period of indigestion, became inebriates. I found that the diet of the family was largely dependent on the surplus of perishable food which accumulated in the store. At one time it was eggs, then fruits, then grains, then meats. This diet was insufficient, and states of starvation and defective growth followed which led most naturally to the narcotic of alcohol. In another case two sons of a clergyman began to use alcohol to excess without any apparent reason. The theory of the parents that excess of quantity and variety of food was dangerous, had been carried out from infancy. A limited and always insufficient quantity of potatoes and bread had constituted the daily food. When these children grew up they ate to great excess away from home. This, with starvation at home, broke up the normal nutrition, and the relief from alcohol was so great as to be irresistible. In a case of unusual mental ability where the user of spirits was of an exceptional character, and the effort to recover was of equal intensity to the craze for drink, it was found that regular, uniform diet of moderate variety of foods was medicinal. As long as his diet was mathematically uniform and unchangeable he could keep from spirits, but the slightest deviation in time of using food and their quantity and quality would destroy his mental control. It was ascertained that his mother, during pregnancy and lactation, entertained some opinions of foods and their value and put them in practice in her own case. The result was a very sensitive nutrient organization in the child, with anemic sick headache throughout childhood, great excesses at puberty in foods and drinks and continued nutritive disturbances up to manhood. Then a period of drug-taking and periodic inebriety. Now he is able to be a total abstainer only by the most careful attention to diet. There appears to be a close relation between the excessive use of meat in childhood and inebriety in early middle life.

While the facts are not sufficient from which to draw any general positive conclusions, there are many reasons for supposing that often they are as cause and effect. This appears clear in this case: The parents in a family entertained very strong confidence in the value of meat as an ideal food. It was used and urged upon the children in all forms. One boy began to drink in college and died after a short period of great excess. A sister was hysteric and became a drug-taker, and died early. Later the parents abandoned meat for grains and fruits, and three children brought up on this diet have continued well and healthy. The conditions and surroundings are the same, but the vigor of the children varied widely. Beef-eating foreigners who bring up children on this diet are astonished that their children turn to beer and wine so early. The reason is the early and deranged digestion which, calling for relief of some kind, finds it in alcohol. This question of the value or injury from meats and grains is yet to be studied and settled. After alcohol is taken to excess, the complications of nutrition are many and serious. One of the first essentials in treatment is the elimination of toxins and proper nutrition.

Foods of easy digestion with moderate variety and quantity, and taken at regular intervals are required. Concentrated foods may be useful in some cases and injurious in others. Frequent use of food and in large quantities is to be avoided.

Two conditions exist, impaired and defective nutrition and congestion from over-accumulation of toxins and waste unassimilable foods and starvation. The treatment is not by routine or specifics, either foods or drugs, but by the use of many and complex measures to meet the special conditions called for. Inebriety is not confined nor traceable to any special cause, and its treatment can not be successful by any one measure or form of drug. The unexpected outbreak of the drink craze in early life and the persistence of the use of spirits is unmistakable evidence of some central defect of nerve centers and neurons. These defects are most likely to come from nutrient degenerations in what way no one can tell, yet the facts point out a distinct relation.

The drug poisoning from alcohol, opium and other narcotics most clearly affects the nutrition, and in all cases is followed by veritable starvation and failure to assimilate the food required. Where causes are traceable to early life the degeneration is greater and the symptoms more complex. The same nutritive problems appear in all cases. The use of tea, coffee and wines at meals in early life is a starting point for both degeneration and inebriety later. Many of the most intractable cases of pronounced degeneration where the alcoholic symptom was maniacal have a history of early tea and coffee drinking. The facts fully sustain the assertion, that a large number of cases of inebriety are traceable to defective nutrition in early life. This may be both starvation and poisoning, and the extreme persistence of these states is remarkable. Thus the bad living of childhood with its defects of nutrition may appear in later life as in the following: A child of healthy parents who were killed by accident, was kept six years in the family of a German and wine drinker. He was over-fed and given wine freely at the table, and was considered sickly. Then he was taken by another family and brought up very carefully and abstemiously. After a long temperate life he retired from business at sixty, and soon after began

to over-eat and drink wine at meals, and finally became an inebriate. Many cases are traceable where inebriety began at or before puberty, or after then subsided and later in life broke out again without any special causes. The expression "sowing wild oats" often describes a period of excessive use of spirits and nutritional disturbances, and then a full subsidence and a long period of temperate living. Far down in middle and later life a recurrence of this excess period appears again and often death follows. Here there is a persistence of nutrient and poison effects, which breaks out like some masked fire which has been dormant for a long time. The appearance of inebriety is usually sudden and without any exciting causes, and the change in conduct and manner of living is unexplainable. The same methods of using spirits and the same food impulses and tastes, and same surroundings as far as possible, appearing after a lapse of a lifetime, show that early defects are not affected by time. I conclude at this point with a summary of what I have intended to make clear in this study:

1. Inebriety is a most complex neurosis. The causes are equally complex, and include all the various states of degeneration which influence and disturb nutrition.
2. Obscure indigestion begins, and for this drugs and bitters containing alcohol are used. The narcotism which follows is so grateful that it is continued.
3. Dietetic delusions are fostered in the minds of parents and children, and from this many different forms of inebriety begin.
4. Often the most maniacal and chronic inebriates are from these delusional dyspeptics.
5. Starvation is present in many of these cases. The quality and variety of foods are deficient and defective nourishment follows.
6. The uniformity of taking foods and the quality and variety are essential. This and nutritional rest and mental anxiety are important factors.
7. The inebriety following these conditions is successfully treated by elimination of the toxins and special correction of the nutrition.
8. Nutrition is a very active cause in the production of inebriety, and should receive a careful study in all cases.

DISCUSSION.

D. R. BROWER, Chicago—I am pleased to have heard the admirable paper of my distinguished friend, Dr. Crothers. No man can speak with more authority than he can on the etiology and treatment of inebriety; and what he says is as sensible as it is learned.

It is very gratifying to see so much interest being manifested by the profession on the subject of dietetics, for there is no more powerful agent in the causation and cure of diseases. The recognition of the fact that imperfect digestion leads to auto-intoxication, and this to development of diseases of the nervous system, and the further fact that inadequate or improperly cooked food will produce the same result have been of much benefit to all concerned.

The publication far and wide of further facts that tea and coffee in childhood will develop a taste for stimulants that later along will produce inebriety, will save many from this dreadful state. The use of tobacco by the young may also be an important factor in this same pathogenesis.

Dr. CROTHERS (in closing)—The special object of my paper was to call attention to the injuries which always follow the use of alcohol in children. A very large amount of experimental evidence from the laboratory, in the use of alcohol on animals has been gathered for other purposes, which makes the facts conclusive. The disability and defects of children in all circles of life who have used spirits freely in childhood are to be seen in every town and country. I am pleased to most heartily agree with the speaker who preceded me, in the statement of the skill in promoting the growth of animals, in fattening them, in developing their best qualities, so highly developed among stockmen and farmers, while the develop-

ment of children physically through food channels, is totally neglected. We are on the frontiers of a new field of much important work, prominent of which is to clear away the delusions which infect our conceptions of child growth and dietetics. One of these delusions is the food value of spirits and its harmlessness in early life. Our foreign population have strong views of alcohol or beer in childhood. Many others cling to the idea of stimulation and increase of vigor from spirits. These delusions must be overcome and a clearer conception of dietetics as a whole must follow, then we shall do with children what farmers do now with animals.

TUBERCULOSIS: ITS HYGIENE AND DIETETICS.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY A. T. CUZNER, M.D.

GILMORE, FLA.

Tuberculosis in some form or other may fairly be considered the almost universal disease of man. "Schlenker made 100 consecutive postmortems on adults and children. He carefully examined every part of their bodies and found 65 per cent. tuberculous. In over 4000 successive postmortems made in Breslau in 1893, one-third of the bodies contained gross tuberculous lesions. If the microscope had been used, probably enough lesions could have been discovered to make 2500 infections. Babes found lesions of the bronchial glands in more than one-half of his postmortems on children. Biggs could demonstrate characteristic lesions in the lungs alone in 60 per cent. of his postmortems. Grawitz found primary tuberculous deposits in the lungs in 152 out of 221 cases, being nearly 70 per cent. of all infections. Loomis found the bronchial glands infective to rabbits in eight out of thirty bodies apparently free from tuberculosis during life."

Upon examination of the death records of thirteen prisons located in different parts of the country, we find the deaths from tuberculosis to be 59.9 per cent. Doubtless tuberculous deposits could be found in the 40.1 per cent. remaining.

In an article in a September issue of the *Illustrated American*, Prof. Fletcher W. Hewes publishes a dial illustrating the ratio of deaths in the United States from the most prevalent diseases. This is a reproduction of the dial.

In proceeding with our investigation of this disease, it will be as well to consider as briefly as we can: 1, the cellular pathology of the human tissues, and then in addition, what is known of the pathogenic germs thought by many to be the main cause of the disease: 2, the nature of tubercle, from which the disease takes its name; and 3, the hygiene and dietetics of this complaint.

CELLULAR PATHOLOGY.

Animal tissues are resolvable into an aggregation of morphologic units or cells, each having a life history of its own. At their death they are resolved into effete material, very deleterious to healthy cells, if retained in the tissues. Many tissues when diseased become the home of minute forms of life—pathogenic bacteria. All cells are the result of the life of previous cells, "*omne vivum ex ovo*."

In the course of its development, every cell proceeds from the condition of a unit, in which it resembles every other morphologic unit, through a series of stages of gradually increasing divergence, until it becomes an element or part of a special tissue. The vital functions of the cell may be enumerated as follows: Contractility, irritability and automatism, reception of nutritive material and its assimilation, metabolism, secretion, excretion, and finally reproduction. All cells are sensitive to and influenced by their environment. They are repellent to deleterious influences in proportion as they possess that force or principle which we call vital. On the contrary, as they lack this force, they are open or subject to the invasion of disease. This may be in the form of toxins, or pathogenic germs, or both combined.

The healthy cells of animal tissues are antagonistic to the invasion of disease. All cells, whether of animal or vegetable origin, fulfill alike the law of their being; derived from a parent cell, they are nourished, develop, reproduce and die. During their life history they are favored or injured by their environment and circumstances over which they have but slight control.

Take, for example, cells of animal tissue exposed to contact with the atmosphere and subject to its vicissitudes, such as low temperature and sudden changes, their force (we call it vital) being reduced to a very low ebb for the time being; in contact with such cells is brought the ubiquitous microbe and there is at once inaugurated a conflict; which will come out victorious depends on various circumstances. If the animal cell has sufficient resistance, then the microbe is a failure. On the other hand, should the vitality and resisting power of the cell be very low, and other circumstances favorable, then the microbe is rampant. This may be called the irrepressible conflict sung of by the poets.

BACILLI

Bacteria, microbes, schizomycetous fungi, are minute vegetable organisms causing the different known fermentations, and found associated with certain diseases, of which they are considered by many to be the cause.

"Bacteria in shape show three varieties—*bacillus*, pencil or rod; *coccus*, a ball, and *spirillum*, a corkscrew." Tubercle bacilli are in length one-half to one-third the diameter of a red-blood corpuscle, and their breadth is about one-fiftieth of their length. (See Fig. 1 a.)

BACTERIUM.

There is a cycle of changes in the life of a bacterium that is shown plainly in the illustration. First, *a*, the spore is seen to lengthen to *b*, and forms a rod *c*. This by elongation and by fission produces more rods, *d*. These remain apart, *e*, or join together to form a chain, *f*. Some of the rods lengthen into filaments, *g*. These develop spores, *h*. The spores being set free, *i*, the series of changes begins again.

"For thirty-five years observers have noticed the bacillus of Koch living with the vinegar yeast. Botanists were divided in opinion whether they were inseparably a part of the life history of the *mycoderma aceti*, though nearly always found associated. Some botanists thought they were indispensable parts, and some thought not. They are the babies of the vegetations, and can be propagated as babies." (Ephraim Cutter.)

"I have long ceased to regard all the bacilli, micrococci and bacteria as the ultimate forms of animal or vegetable life. I look upon them as simply the embryos of mature forms, which are capable of propagating themselves in this embryonal state." (Salisbury-McNaughton's prize essay on Malaria.)

Microbes play a very important salutary part in the science of agriculture. They act as nitrogen suppliers to the soil. They are very useful to the dairyman, causing as they do that peculiar fermentation that renders cheese so palatable. They are ubiquitous. The air we breathe swarms with them. This is proved by Professor Tyndall. The food we eat, the water we drink, alike furnish them an abiding place.

The writer's view of the functions of the microbe is as follows: The cell formation of our bodies is constantly dying, as the life force leaves it and its work is done. The same principle holds good through-

Fig. 1.—Bacterium.

out organic nature. All organic tissues undergo three distinct phases in their history—growth, decay and disintegration, and these three processes may go on simultaneously. In consequence of the dying of the cells, there is a continual accumulation of dead matter that must be disposed of by some process or processes. As one of these, the microbe gets in his work. Each microbe has his own particular work to do. In certain stages of tuberculosis we find more than one microbe associated with the disease. I do not think microbes deserve the ill repute in which they are held. When the human organism is diseased, microbes are found to be much more abundant, the dead matter to be changed and eliminated requiring much more work on their part. Like the buzzard, they are always ready to remove dead and offensive animal tissues. They also act as media of disease, just as flies do. They have likewise the power to impose upon the cell a certain amount of force, that tends to produce a condition most favorable to their disintegrating work.

Dr. Austin Flint admitted the importance of the tubercular bacillus in disease and, as quoted by Dr. H. B. Weaver, said: "You take away their lives, when you take away the means by which they live."

Dr. Andrew H. Smith, quoted by the same writer,

said, in speaking of phthisis: "The fact should be recognized, that tubercle bacilli never become implanted in the healthy system. There is always an abnormal anterior condition that should receive our attention. . . . By sufficiently improving the nutrition, you lift the patient above the plane on which the bacillus flourished."

Solis-Cohen, also quoted by this same author, says: "To make our conception of the disease sufficiently comprehensive, we must include other elements than the bacillus and the changes in cellular structure or chemic constitution of solids and fluids brought about by its activities. . . . That condition which makes the human tissues a 'receptive soil,' a favorable 'culture medium' for the tubercle bacillus—that condition which of old was called a 'diathesis' or 'susceptibility,' is *itself* a disease, a departure from the *norm*, and I believe it to be the most important element in the morbid complexus termed tuberculosis. . . . It is the element requiring the greatest care in the prophylaxis, the most intelligent and faithful treatment."

Dr. Weaver says: "We believe this cachexia, this predisposition, which may be inherited or acquired, is a defective nutrition, superinduced by a want of vital energy, which has its correlative in the histologic expression, in the place of normal tissue, elements of abnormal condition and lowered vitality. We know that tuberculosis is not the product of a truly inflammatory process, neither is it a neoplasm, for it tends

deposition of tubercles in the cells and tubes of the lung tissues, and the changes this material "suffers and works." While this position has not been wholly abandoned at the present time, it is now considered by a majority of the profession, that the tubercular bacillus of Koch is the main predisposing and exciting cause of consumption. The endeavors of the bacteriologist are, therefore, mainly directed to the destruction of the germs within the body and preventing access of fresh germs from without.

The following synopsis of tubercle is from the works of Charles J. B. Williams: "Tubercle presents the following characters: When first deposited it is a clear viscid, albuminous substance, becoming more and more solid by coagulation, as does fibrin, but differing from it in being incapable of organization. When more or less solidified it loses its transparency, becoming grey, yellow or drab. Usually it is friable and of caseous consistence. Tubercle may be variously deposited in small, isolated points termed "miliary"; in granular masses, distinct or confluent; infiltrated diffusely into parenchyma; or aggregated in a mass, and enveloped by a cyst composed of surrounding tissues, thus constituting a tumor. [*The formation of this substance is merely a perversion of nutrition.*—Cuzner.] This is the commencement of the change to which the lowest forms of tubercle tend—that of maturation and softening."

Rokitansky thus describes the softening of tubercle: "After the tubercle has existed for some time in a state of crudity, it becomes, as it were, loosened in the textures, and breaks up on slight pressure and becomes more moist, then changes into a yellowish dissolving casein—like fatty and viscid matter. In the different changes in tubercular matter, as well as in the original deposition of this matter, the adjacent living parts have considerable share. A miliary tubercle from its first formation may become a cause of irritation to contiguous textures. The amount of this irritation and obstruction will depend on the natural excitability of the part, its functions, situations and size of tuberculous deposit."

The following is from the JOURNAL, from the pen of John McFarlin, M.D.: "Tuberculosis is primarily an inflammatory process. Every tubercle begins its history as a single inflammatory node, not very different from those produced by the introduction of foreign particles in the tissues. In the early stages of the disease there is rarely any marked symptomatic involvement, and many cases progress to the considerable destruction of organs before constitutional symptoms are observed. Up to a certain stage, therefore, tuberculosis is not essentially different from any ordinary or non-specific focal inflammation. It is as the disease progresses that the difference is observed; for as the cause of the disease is alive and engaged in growing and propagating its kind, there is a progressive tendency of the disease-producers to disseminate and new inflammatory foci to form; and, as growth means metabolism, there are waste products of the growth to be absorbed and eliminated.

"This is by no means all of the pathology of the disease. The tubercles develop at the expense of the organs whose tissues, transformed into or replaced by the tuberculous tissue, are unable to perform their functions or do these so insufficiently that disease must result from their incomplete action. Lastly, the tuberculous nodes, in which no blood-vessels are

Fig. 2.—a, yellow tubercle; b, gray miliary tubercle.

neither to resolution and repair, nor to proliferation and persistence. Its tendency is to destruction without subsequent repair. It is necrosed coagulation without blood-vessels, without cell organization, without life—it is death."

Dr. Weaver goes on to say: "Therefore, we conclude with Cohen, that when, in the course of ordinary wear and tear, or extraordinary wear and tear, or following inflammation or injury, or from any cause or combination of causes, degraded tissue elements have been produced, it is highly probable that the tubercle bacilli or other microbes, finding therein a favorable soil, modify by their activity the further evolution of the disease."

Consequently, in summing up the facts, as reflected by both observation and experience relative to the causation of tuberculosis, we think we are warranted in the following conclusions: 1. Malnutrition is the starting point of tubercular process. 2. While the bacillus of Koch is, perhaps, the most important of the several microbes that influence the progress of the lesion in the various forms of the disease, yet it does not itself originate the disease in any form. 3. Both factors—the dyscrasia and the bacillus—must exist in combination before there can be tuberculosis."

TUBERCULOSIS.

In the days of my student life, it was held and taught, that phthisis pulmonalis was caused by the

formed, constantly soften and disintegrate with the frequent formation of holes or cavities, in which, if they communicate with the outer air, saprophytic bacteria are likely to grow and the harmless, or oftener harmful, results of their metabolism are absorbed into the blood. Death is more often the result of destruction of organs, suspension of vital functions from local lesions and profound secondary anemia, than from any poisonous principle in or produced by the bacillus."

INEBRIETY AND TUBERCULOSIS.

Dr. T. D. Crothers, in an article in the April JOURNAL, on the subject, "Inebriety and Tuberculosis," says: "Alcohol acts on the body psychologically, physiologically and pathologically, and is literal paralysis and dissolution. No other substance known, in common use, has such profound destructive action on waste and repair of the body. This opens the door for many diseases by destroying the power of resistance and enfeebling all the powers of life." Speaking of inebriates, he further says: "In my experience

with 2000 cases, fully 20 per cent. are associated with tuberculosis." . . . "The use of alcohol results in deranged functions and disturbed energies. The two central processes of life—waste and repair—are affected, the first increased and the last diminished."

As we stated before: "All cells are sensitive to and influenced by their environment. The microbe has the power to impress upon the cell a certain amount of influence that tends to produce a condition favorable to its disintegrating work. To illustrate how it is possible for one organism to influence another so as to minister to its wants, we will state the result of some studies we have made in natural history. We will examine a common gall called "oak-apple," the result of the puncture made by a small fly called "Cynips," of the order *hymenoptera* (see illustration). Galls are vegetable deformities or excrescences, due to parenchymatous hypertrophy, and according to the

definition of Lucaze-Duthiers, comprise "all abnormal vegetable productions developed on plants by the action of animals, more particularly by insects, whatever be their form, bulk or situation." The Cynips appear to prefer to puncture the limbs, twigs or leaves of the plants subject to their ravages, *that are not possessed of as great a degree of force or vitality as the remainder of the plant.* The influence of the puncture of these insects, or of the poison they inject, or of the egg they deposit by means of their ovapositions, or of all three combined, has such an effect on the infected vegetable tissue as to cause them to become hypertrophied and take on a further growth and development, by means of which the egg, larva and future fly are provided with a home and sustenance until such time as the fly is prepared to quit the gall. In addition to this (as will be seen in the illustrations from life) the grub and future fly are incased in an egg-shaped cell which is inclosed in a cavity in the interior of the gall. Leading from this cavity to the rind of the gall, so to speak, is a canal. In the ovoid cell in the interior of the gall, the grub is so placed that the future fly has its head always pointed toward the canal leaning to the exterior covering. When the fly is fully matured, it gnaws through the thin ovoid cell, and crawling through the canal until it reaches the exterior covering, punctures the same and escapes.

CAUSE OF DISEASE.

In summing up from the above examination, I think we may reasonably conclude *that tuberculosis is a disease of malnutrition of the tissue elements of the body*; that the bacillus, while it has considerable work to do and has great influence over the course of the disease, *is not the prime factor or cause.* We may further conclude from the vast clinical experience we have in evidence that there is no known germicide that is capable of destroying the microbes without causing destruction of the tissues or the life of the patient, and that all measures adopted in the past to destroy the bacilli have not obtained sufficient success to warrant us in looking in that direction with much hope for the future.

The bacilli, as we said before, are ubiquitous. If we destroy those in the body today, we have our work to do over again tomorrow. We can not continue indefinitely to act the part of executioners. Are we then to abandon the field as beaten scientists? Not while there is so much to encourage us in the clinical experience of the past.

Since writing the above, we read a curious account of the death of five out of the six Esquimaux Lieutenant Peary brought to the United States. They all enjoyed good health as long as the blubber they brought with them lasted. After it was all gone they began to pine, and successively became affected with coughs and lung troubles; finally they all died but one; this last was also expected to die, if not sent back to the arctic regions.

CURABILITY.

Notwithstanding the great mortality from the disease, overwhelming testimony is accumulating daily to the effect *that if taken in its earliest stages, before the system is exhausted by its inroads, it can, and has been, cured in numerous instances.* Again: Who that has made many autopsies but can testify to cicatrices found in the lungs, the result of the cure of a former tuberculosis? The late Austin Flint used to

teach in Bellevue, over thirty years ago, that the disease was curable if taken in its earlier stages.

The following is from the pen of E. B. Borland, M.D., and is taken from the JOURNAL. "Tuberculosis, uncomplicated with sepsis, may be considered a curable disease, in the sense that it may be held in abeyance, that is to say, kept in a latent condition for a lifetime, providing the vital resistance of the individual is kept up to the normal standard. Nature has been known to completely eradicate in a limited number of cases."

There are without doubt many more recoveries from tuberculosis than the average physician or the laity have any idea of. The postmortems of Schlenker, Babes, Biggs and Grawitz demonstrate this, as is shown in the beginning of this article. It is a common belief that *no one has consumption who does not die of it.*

Continuing, Dr. Borland says: "The scientific physician will endeavor to imitate nature as far as he can interpret her methods. Investigations in search of an antitoxin have demonstrated that there is no immunity against tuberculosis when the three essential factors of infection, viz., debility, abrasions and bacilli are present. [*If there is anything in the theory of immunity a child born of an infected mother ought to be less liable to infection, other things being equal, on account of its being almost constantly inoculated with toxins during intra-uterine life.*—Cuzner.] The question arises, can tuberculosis in its latent stages be cured in all, to all intents and purposes? It has been demonstrated that two-thirds of all infections either disappear or remain quiescent during an average life. If nature can accomplish so much under the reign of empiric medicine, what will she be able to do when the physician concentrates all his energy on building up and maintaining the vital resistance of cell-life, and keeping septic germs, as well as tubercle bacilli, away from the latent infection?"

The following is also from the JOURNAL, by John Hey Williams, A.M., M.D.: "Eighteen years ago I was myself an invalid, suffering from supposed tuberculosis. I say supposed, having then no means of positive diagnosis. I was advised by such eminent authorities as Da Costa, Weir Mitchell and the lamented Pancost, that I could not live a year longer in Philadelphia, and that a change of climate was necessary. My attention was drawn to North Carolina by the writings of Hon. E. J. Aston and the reports of Dr. J. W. Gleitsman. A few months' residence in Asheville, and a more thorough knowledge of its climatic attributes, decided me to take up my residence there. With passing years came confirmed health, and I have remained eighteen years with pleasure and profit."

The careful reader of what has already been written, will doubtless arrive at the same conclusion as the writer, viz., that *this disease is caused by, or is the result of, malnutrition of the tissues involved*; that the microbe takes an active part in its manifestations, and that the disease is curable.

As to the treatment indicated: Shall we endeavor to destroy the microbe, and with this object in view continue to experiment with *serum therapy*, or shall we by a rational system of hygiene and of nutrition, build up and fortify the system against the inroads of the bacillus?

As to hygiene: There can be no doubt that an abundance of pure air and sunlight go a great way

toward arresting this complaint, therefore those afflicted with this disease in its earliest stages, should by the advice and direction of their physician, seek that country where the largest amount of each can be obtained during the year.

CLIMATE.

There has been considerable difference of opinion, and much discussion as to the most desirable climate for preconsumptives. The writer prefers Florida as a place of residence for such, for the following reasons: 1, in Florida there are more days in the year in which it is possible for a patient to be out in the open air and enjoy the sunshine, than can be found in any other State; 2, the climate and temperature are more equitable than in any other State. This is my personal experience of ten years, and is in accord with the reports of the U. S. Weather Bureau. However, each patient has idiosyncracies of constitution which render him or her a law unto themselves in this respect as to climate. Some patients do better in mountain air, while others receive much more benefit from a voyage on the ocean. Some are better served by a dry air, others by a moist one. I think it may be safely affirmed that the average individual but seldom uses over 75 per cent. of the air-vesicles, 25 per cent. remaining in a collapsed condition. These unused vesicles are prone to take on disease. I hardly need remind any one that failure to use means partial paralysis. Again, the object of respiration being to obtain a supply of oxygen to be used in the vital functions, any diminution of the supply means low vitality.

There is a very instructive article in the *Medical World* for October, 1897, of which the following is a synopsis: "Dr. W. F. Ball, Mountain Station, Ohio, writes that in 1851-2, he contracted a dry, hacking cough, with morning expectoration; had chills and hectic fever for months, and lost much flesh; was pronounced by several physicians as incurable. At this time an old Canadian doctor visited his father. 'He examined me thoroughly, and said there was only one way to save me, which was to carry out his instructions faithfully. I was to sit up in bed and throw shoulders up and backward, filling the lungs with air to their utmost extent, until pain would warn me to stop; then to press down on the air to make it fill every cell. The closed cells, which were sealed by adhesions so that they could not be opened, were thus surrounded by healthy cells, and the diseased tissue would suppurate and be thrown off. It worked exactly as he told me. I have practiced these inhalations for over 40 years, and I can now, at the age of 62 years, expand my lungs to such extent as to increase my chest measure five inches, and I never have a cough to trouble me.'"

HYGIENE.

It was formerly held that breathing the same air with a consumptive was highly dangerous. It is now believed that only the desiccated sputa breathed into the lungs is infectious. There can be no doubt that a certain amount of morbid material is exhaled with each expiration. Carefully conducted experiments with the condensed moisture from crowded auditoriums prove this. Very highly offensive putrid albuminoid substances have been obtained in this way. Crowding consumptives into large sanitariums, in my opinion, is not good practice. Far better for such patients to live in homes by themselves and attendants.

"Sunlight is nature's disinfectant, and experiments have shown that direct exposure to its rays for a few hours will destroy such germs as tuberculosis. The old method of exposing infected linen, carpets, etc., to the sun has thus been proven of value, and the rays of the sun must often destroy many of the bacteria present in infected hospital wards. This influence is also beneficial in destroying many of the bacteria deposited upon the surface of the earth, and even the upper layers of rivers must be somewhat purified by the agent." (Prof. A. C. Abbott, Philadelphia.)

The sputa should be received into paper receptacles to be afterward burned. We find in nature, that living beings, animals, plants, and living tissues, whether of animal or vegetable origin, are continually undergoing certain processes, viz: growth or development, decay or death. Both these processes go on simultaneously. Professor Hammons says: "If we could perfectly adjust these so as to balance each other, man might live on forever." By a partial adjustment, we have increased the average longevity several years.

If the excreta of any kind are retained in the tissues, they produce disease, which is a slow form of death. If, after they are removed from such tissues, they are absorbed or applied to other living tissues they produce disease. If not thus absorbed such *excreta* undergo further change or decomposition when exposed to the action of heat and moisture in the open air, evolving during such process foul gases very injurious to life. But when placed in that great stomach of nature—Mother Earth—they are so digested that they are capable of becoming, by the absorption of different plants, parts of living organisms. In densely populated communities the sewerage system of disposal of excreta is adopted.

In an editorial in the London *Lancet*, the editor, in speaking of the sewerage system says: "After all, it is not a perfect success. Besides defiling the Thames to such an extent that the stench from it is quite perceptible, the gases that arise from the opening of the sewers at every corner, and are inhaled by the passers-by, are largely the cause of the many cases of diphtheria and typhoid fever which exist in this city."

It is a query in my mind whether it may not be better for us to modify our plans of disposing of the excreta and waste material of cities; whether the sanitary laws adopted by the Jews under the instruction of Moses would not be better. We find that the Jews had their Gehenna, or hell fire located in the valley of Gi Hinnom, outside the walls of Jerusalem. In this fire was consumed all that was vile and likely to taint human life. Without discarding the sewerage system, might we not supplement it more fully than is done at present by the crematory system of disposal of all offensive substances? In the family this process might be more largely used. Let everything be burned in the stove that can not be passed down the sewers, or buried deeply in the ground, if they live in the country. Col. George Waring of New York states that "the foulest sewerage water passed through ten feet of clean sand comes out clean and pure." This brings us to the consideration of a water-supply.

PURE WATER.

It is very important that tuberculous patients should have an abundant supply of pure water. Water being a universal solvent of organic material, it is therefore

very necessary that no filtration from closets or cess-pools be allowed to contaminate the source of supply. I prefer and instruct my patients to drink large quantities of hot water, as I believe this promotes excretion of deleterious substances from the body, and adds to its functional activities. Frequent bathing of the body is of great use to patients. A sponge bath at night will often allay excitement and give patients rest.

EXERCISE.

Light exercise should be indulged in as far as the strength will permit, especially lung exercise. Many individuals with lung trouble have been cured by learning to play the cornet.

DRUG THERAPY.

Every qualified physician will administer such drugs to his patient as may be required by the particular phase the case may present from time to time. Before leaving the therapy of this complaint I will record my experience with those medicines we may properly call reconstructives; viz., nuclein, either Auld's or Vaughn's or the protonuclein of Reed and Carnrick. Either of these should be administered continuously for months, even after the patient has seemingly recovered from the complaint. The administration of these preparations appears to be, to increase and improve the blood elements of the body.

DIET.

We now come to what, in my opinion, is the most important part of the treatment of tuberculous patients, viz., the diet. With regard to diet, it should largely consist of animal foods. Of these, eggs and milk should preponderate. I prefer to give eggs raw when tolerated. The albumin of the egg is similar to blood albumin, and is digested, or rather, it is absorbed into the blood without undergoing an elaborate digestive process. I have found the white of the egg mixed with water, tolerated when the yolk could not be borne by the stomach. Bone marrow of the ox is of greater value than cod-liver oil. Good creamery butter should be used freely, and to accomplish this result it should be spread *thickly on very thin slices of bread*. Heavy meals should be avoided, but food should be partaken of in small quantities between meals.

Beef feeding, as introduced by Dr. J. H. Salisbury, and largely practiced by Dr. Ephraim Cutter and others, is a wonderful power for good in the nutrition of consumptives. Beef-tea made from beef-extract, I consider positively injurious. It taxes unduly the excretive functions of the body, and has very little nutritive value. It is largely stimulating in its action. When I use beef-tea in my practice I have it prepared as follows: Take a small quantity of gelatin, say about one teaspoonful, and dissolve the same in a cup of hot water. When dissolved add a small quantity of extract of beef for flavoring and stimulating purposes, then add a little salt and pepper. Fruit should be partaken of freely. In fact, the aim of the physician should be, to endeavor by means of all the resources that the science and art of medicine has placed at his disposal to add to the digestive and assimilative powers of his patient, and thus give him or her the greatest chance for a cure of the diseased tissues. I might continue this subject of feeding indefinitely, but enough has been written to show its supreme importance.

INFLUENCE OF THE MIND UPON THE BODY AND ITS RELATION TO EDUCATION.

Presented to the Section on Physiology and Dietetics, at the Fortyninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY RANDELL HUNT, M.D.

CHAIRMAN OF SECTION ON PHYSIOLOGY AND DIETETICS, A. M. A.
SHREVEPORT, LA.

Involving, as this subject does, a comprehensive knowledge of the brain, nervous system and body, their relations and inter-relations, connections and nice dependencies, an overestimate of it is impossible. Though its importance has been recognized for centuries in all the great philosophic treatises of the Aryan peoples, the ideas presented in them have been so entirely spiritual and ethical as in no way to suggest the existence of the psycho-physical law underlying the whole.

The first to clearly perceive and appreciate the existence and potentiality of a psycho-physical law underlying the phenomena arising from the influence of the mind upon the body were Unzer and John Hunter. Since their time, the subject has been ably studied by such men as Muller, Elliotson, Laycock, Braid, Carpenter, Tuke and Haidenhain, who have assiduously devoted their lives to the scientific elucidation of this problem upon purely psycho-physiologic principles. Such is the fruit of their inestimable labors, that the medical profession gives to these workers its highest gratitude and respect, and perceives in the future development of man the raising of a monument to them more lasting than stone, for their researches have practically established the fact that no mental modification can occur without a corresponding change in the body.

A primary purpose of this paper is to demonstrate that through Intellect, Emotion and Will the mind exerts an enormous influence for good or for evil upon the sensations, movements, and organic functions of the human body.

Intellect is the power of the human mind that adapts means to an end, guides the feelings, and enables its possessor to find out and act through knowledge. It acts upon the body more particularly through imagination, with which expectation, sympathy, belief, faith, imitation, and hope are closely associated. Attention also plays a remarkable part in consciousness, in its relation to physical phenomena, and though in one form, an act of the will must be included under this head, prolonged attention giving clear consciousness and good memory, while mind, through attention, concentrates and perceives itself—knowing, feeling and willing. The persistent development of attention is one of the most important and practical factors of successful education, increasing, as it does, the natural growth of perception and conception, which are aptly termed by James the very backbone of our thinking.

The production of psycho-physical phenomena through active attention was understood by John Hunter, who says: "I am confident that I can fix my attention to any part until I have a sensation in that part;" while the power of ideational upon sensational centers is affirmed by Muller, who shows that "ideas do not act merely upon the motor apparatus by which they are expressed, but as frequently affect the organs of sense, which then present sensorial impressions or images of ideas." Insensibility to phys-

ical pain occurs when the attention, modified by expectation, is powerfully arrested in a specific channel, the body failing under the circumstances to appreciate even the application of strong stimuli. "During the year 1862," writes Dr. Braine of Charing Cross Hospital, "I was called upon to give chloroform to a very nervous and highly hysterical girl, who was about to have two sebaceous tumors of the scalp removed. On going into the operating theater, it was found that the bottle containing the chloroform had been removed to the dispensary, and on testing the Snow's inhaler, which at that time I was in the habit of using, I found it to be quite devoid of even any smell of chloroform. Then, having sent for the bottle, in order to accustom the girl to the face-piece, I applied it to her face, and she at once began to breathe heavily through it. When she had done this for about half a minute, she said: 'Oh, I feel it, I feel that I am going off,' and as the chloroform bottle *had not arrived*, she was told to go on breathing quietly. At this time, her hand, which had been resting across her chest, slipped down by her side, and she did not replace it. I thought I would pinch her arm gently to see the amount of discomfort her hysterical state would induce her to bear. She did not notice the pinch, and to my surprise, did not seem to feel it at all. Finding this was the case I asked the operator to begin, and he incised one of the tumors, and then as the cyst was only slightly adherent, pulled it away. The doctor then tried the same experiment again, and without any trouble or pain removed the second tumor."

The rejection of the contents of the stomach as the result of expectation is well exemplified by an experiment made by Dr. Durand. He gave sugar-water to a great number of patients at a hospital; then, pretending alarm, said he had made a mistake and given an emetic, the immediate result of which statement was to cause four-fifths of the patients to be really very sick.

2. Emotions are our capabilities to feel in view of ideas; are occasioned by knowledge, and "are strung on ideas as pearls on threads of gold." Some of the emotions look to self and are called "egoistic;" others are termed "altruistic," because they look to others, but the emotions that look to the truth-world and duty-world are called "cosmic," and by physiologists are located in the optic thalamus, quadregemina, pons, and medulla. They act through the cerebrum, upon which they are dependent for ideas, and through the sensory ganglia, by means of which are produced the feelings with which they are associated. That the medulla is the seat of the emotions suggests naturally that undue excitement, in whatever way caused, produces through the vagi and other nerves that arise from it like effects upon the organs to which they are distributed. Emotion may act upon the sensory ganglia and centers of the nerves of sensation, thereby producing any of those sensations ordinarily induced by impressions upon their periphery; and, though really central, these sensations may be referred to the periphery by the terminals, endings of the nerves. Claude Bernard asserts that the same nerve may transmit the sensory current in either direction, to or from the brain. Other emotions occur, due to the influence exerted upon the sympathetic nerves, as in creepiness from fear. Shakespeare describes the effect of shame upon the ear in the following couplet:

Mine ears that to your wanton talk attended
Do burn themselves, for having so offended.

Prof. Ball of Paris tells of an unfortunate fellow that had a quarrel with his mother-in-law and fell into a violent passion. Full of emotion, he went home intending to tell his wife, but to his infinite surprise, found that he was dumb. Treatment, however, soon restored him to a normal condition. Contrast the mild expression of Humility with that of Pride. Fear expresses itself in cries, tremblings, and palpitations, while Courage is bold, quick and firm.

The heart, blood-vessels, and blood are materially affected by different emotions, as are also the lungs, ureters, bladder and urethra. Dr. Beaumont found in case of the man with a fistulous opening in the stomach, that anger caused its inner coat to become red, dry and irritable, always producing an attack of indigestion. It is well known that the menses are arrested by emotions of a violent character, and that infants suckled at the breast of an angry mother, have been known to be made very ill. Jaundice has been caused by the emotions of fear and pain; a fact which can be explained by assuming that the vasomotor dilators have been stimulated, thus allowing, or rather forcing the bile into the blood, its pigment being by this channel disseminated throughout the tissues. Pleasant emotion increases functional activity, promotes metabolism, and actually renews, improves, and invigorates the mental and physical being; though its scientific appreciation consists not only in its recognition, but in its substantial application to the improvement of mankind through educational methods and otherwise.

3. Will is the capability of self-direction, self-termination, and self-action; and makes of man a free agent, subdues the force of violent impulse, and guides the intellectual powers. It acts through the cerebral cortex, striated body, and pons. In health and disease the will can control within certain limits the reflex action of the voluntary and semi-voluntary muscles, while in the early stages of insanity there is often a violent conflict between the will and automatic cerebro-muscular action. All familiar with physiology are aware that by inflating the lungs and by an effort of will restraining respiration, the action of the heart can be almost entirely stopped, producing, however, if too long continued, complete collapse. Colonel Townsend once illustrated his power, through will, to simulate death. Drs. Cheyne and Baynard felt his pulse, and found it sink gradually until, finally, they were unable to detect the slightest evidence of life.

The power of volition over the body cultivated by the fakirs is authenticated by English officers and medical men, Dr. Carpenter giving in his physiology the case of a Yogi that by will suspended the organic functions, was buried for six weeks, disinterred and resuscitated. John Hunter says: "The state of the mind is capable of producing disease; another state of it may effect a cure," meaning by this to imply that one kind of emotion is capable of removing a disease produced by another kind of emotion. Dr. Tuke, therefore, thinks it would be more correct to say "that, as in health certain mental states induce disease, so in disease certain mental states may restore health." Such a statement as the above illustrates the importance of this subject not only to medical men, but to teachers, who will discern at a glance the beneficial

effects of certain ideas, feelings, emotions and volitional impulses upon the minds and bodies of children, as also the detrimental effects of certain others. Practically, the true civilization of future centuries and the continued evolution of the human race seems placed in the hands of mothers and teachers.

Most important is it that we should recognize that through a scientific and judicious observance of nature's laws, in education, in government, in social intercourse, there is attainable a physical, mental and moral perfection that has heretofore been esteemed a mere idealization of the enthusiastic devotee of ethics or religion. That this is a fact is demonstrable through the correlative sciences of physiology and biology, which daily illustrate the dependence and interdependence of mind and body. To the student of nature is proven hereby the absolute necessity of a comprehensive knowledge of these sciences on the part of teachers; through the careful and judicious stimulation of ideas and emotions they may arouse and develop only what is good in the nature of the child.

A realization on the part of instructors of the benefit to be derived from moderate benign emotion, and the contrary effect of malevolent emotion, is bringing about radical changes in prevailing methods of education. All true methods recognize as fundamentally necessary the cultivation of the nervous system through an assiduous observance of hygienic dietetic and physiologic laws, associated with well-regulated efforts toward self-knowledge, self-control and self-perfection. Froebel held essentially the same views, views based on the unity of nature with man, of man with God, of God with all, and the consequent psycho-physiologic building of the inner self. Thus, through the enunciation and demonstration of universal truths, there is being rapidly evolved a new system of sociology and education based upon the grand unity of all, and showing as necessary to the evolution of man the knowledge of mental and physical laws. With such observance will come an era of true manhood and womanhood, showing in lives lived after the pattern of the Master the divine and indwelling spirit of the Father.

DISCUSSION.

Dr. J. F. PEAVY, Atmore, Ala.—Personally, I desire to thank Dr. Hunt for his very excellent paper. I am myself, to some extent, a student of mental phenomena, and am especially interested in this very matter of the mutual relation and dependence of mental processes and physical states. Much of the confusion into which we are liable to fall in the study of this subject, may be avoided by simplifying our conception of mind and body as related to each other. We have been accustomed to regard them as distinct existences, capable of being separated from each other and of pursuing independent activities. Until we rid ourselves of this vagary it is clearly impossible to reach any theory of mental and physical correlation, or any logical explanation of modifications produced in either mind or body by influences impressing the one through the other.

Man is a unit, an organic whole. Certain of his higher physical activities we distinguish as mind. The appetites, the desires and inclinations, the likes and dislikes, the hopes and expectations, are generated in nutritional states of the organism. Upon these are based the higher mental and volitional activities. These affective states are at the same time the cause and the expression of the moving of the organism in the direction of ends in the environment which it deems good. In the pursuit of these ends, innumerable adjustments to conditions are effected in the central mechanism, the brain. Many of these adjustments are performed consciously and intelligently, while others are performed subconsciously and automatically. Those adjustments which involve the element of conscious intelligence are on their subjective faces mental states, yet they are nevertheless expressions of brain action.

Mental states are correlated with definite physical processes in the brain. You can not call up the one without producing the other. Furthermore, these physical processes being affections of the central organ of adjustment, have connections and relationships which make them centers of influence affecting more or less remotely the various organs and functions of the body. Thus the mind, or as I prefer to call it, mental action, influences not only the automatic functions of the brain, but also other bodily functions relegated for the most part to lower centers and controlled only indirectly by the brain through an exercise of inhibitory influence over them. Indeed, influences coming through the psychic life are constantly impressing themselves upon the physical organism and taking the shape of normal physiologic activities. Only the curious abnormalities which now and then arise attract our attention and excite our wonder. In our amazement at these illustrations of perverted action, we are in danger of overlooking the fundamental facts of mental and physical correlation in the human organism.

Certainly there is no more inviting study than that of mental phenomena from the standpoint of the physiologist, nor are there any more important therapeutic questions than those which relate to the proper handling of deviations from the normal in this department of vital activity.

Educators quite generally are now realizing the importance of a knowledge of psychology as part of the mental equipment of the up-to-date teacher. Quite generally, too, is the fact being recognized that the psychology which has value rests upon a physiologic basis. The question of the influence of mental impressions and mental exercise over physical development and activity seems scarcely to receive the attention at the hands of educators which its importance deserves. The alternative question of the influence of physical training and development over mental health and efficiency is receiving, and quite justly too, considerable recognition in modern methods and theories of teaching. Physical culture, drawing and other methods of developing manual dexterity have fully established their value. They serve to develop the motor capacities of the central organ of adjustment. They tend to make men of action prompt to meet the exigencies of life as they arise.

Dr. E. STUVER, Rawlins, Wyo.—Everyone appreciates the great influence exerted by the mind upon the body and the converse influence of the body on the development and integrity of the mind. I shall not enter into any general discussion of this subject, but desire to call attention to one phase of the question which I regard as of very great importance in the application of educational principles. The point which I desire to emphasize is that the child should not be regarded as a little man or woman, but rather as an epitome of the development of the race. If we recognize the fact that its ontologic or individual mental development corresponds to the philogenetic or racial phases of development, through which the race has passed in reaching its present stage of evolution of the mind, we will at once appreciate the fact that, in order properly to direct the evolving mind of the child through its various ages of credulity, inquiry and faith, up to the fully developed age of reason, that the teacher should have, at least, a clear outline conception of the mental evolution of the race. I desire to congratulate the author on his exceedingly interesting and valuable paper.

Dr. L. DUNCAN BULKLEY of New York said that the influence of the mind over the physical frame is an established fact of which it is often very interesting to observe illustrations.

The ready control of the vascular system, as seen in blushing, often upon mental suggestion, or the paling of the countenance from fear, and the cold sweat occurring under mental emotion, are known to all. I have seen a number of cases where localized sweating of the hands or feet occurred most readily upon mental influences. When the mind was diverted the parts remained dry, but when attention was called to the part the perspiration oozed out and even ran off the part. But mental influences can go farther, and even produce direct lesions of structures in various organs, and he mentioned an interesting case reported by Leloir, where fright caused the sudden and severe development of eczema.

Mental influence can also act in an inhibitory manner and arrest secretions, and probably also check nutrition. He mentioned a very interesting case of a perfectly healthy young lady where the shock of a proposed slight surgical operation completely arrested digestion, so that a simple breakfast was vomited unchanged fully seven hours after it was taken, the suggestion of the operation and visit to the surgeon occurring on rising from breakfast.

The influence of the mind has undoubtedly much to do with recovery from disease, and Dr. Bulkley thought that some of the benefit resulting in the practice of specialists was in the influence of the mind in the way of hope and expectation.

SMALLPOX IN CUBA.

THE EPIDEMIC IN THE HOLGUIN AND GIBARA DISTRICTS OF CUBA, INCLUDING A BRIEF REPORT OF THE SANITARY CONDITION OF THE TROOPS IN THE DEPARTMENT.

BY R. S. WOODSON, M.D., U. S. A.

MEDICAL INSPECTOR DEPARTMENT OF SANTIAGO.

The harbor of Gibara is a small, open one and well washed. The town of 10,000 inhabitants, a walled city nicely laid off with cleanly streets, presents a pretty seaport, which, with the assistance of constant sea breeze and sanitation can be made a perfectly healthy spot for occupancy by troops.

The town and vicinity were carefully inspected for a suitable location for camp grounds, and the most suitable site selected, i. e., the open point of land to the seaward of the city occupied by a small Spanish fort—a level promontory in close proximity to the only available water-supply, consisting of a large, well-cared-for public cistern. The camp was nicely laid out, the fort taken as a guard-house and carefully disinfected, and an adjacent empty house designated as a hospital. Inasmuch as smallpox was prevalent in the city the command was placed in rigid quarantine, and it is recommended that no more troops be sent to this district until the sanitary situation can be controlled.

The mayor and health officers were next visited, and I was informed that for the past three years the city had been badly infected with smallpox and dysentery, that there had been over 1000 cases of the former with 250 deaths since Jan. 1, 1898, and that there had been over 800 deaths from all causes during that period. I took charge of the sanitary situation at the request of the military commander and instituted the following reforms and measures:

1. The Red Cross supplies, which were abundant, and which had been withheld from distribution by the Red Cross agents, were seized by military force.
2. An isolation hospital of 100 beds, fully equipped from Red Cross supplies, was established outside the city walls in the direction of the infected district.

Fifteen male and female immune nurses were employed at twenty and fifteen dollars respectively; an immune guard of eight men under charge of Sergeant King (M.D.), Company G, Second U. S. V. Infantry, were detailed as a permanent guard and acting hospital-corps detachment. Captain Massie (M.D.), Company G, Second U. S. V. Infantry, was placed in command. In two days forty patients were isolated and under treatment. The shed building, 300 feet long, was divided and subdivided for white and colored, and male and female. Two efficient cooks were employed and a well-stocked commissary established from Red Cross supplies. A detention hospital was then established in an adjacent building, and a large house on an adjacent hill was rented as a paying hospital for female patients of a better class. All infected houses of present and past cases were marked with a red cross to be disinfected. Just beyond the city wall is a settlement of 350 people in small thatched huts, badly infected and containing many cases, which will be isolated. At the suggestion of the commanding general of this department, these huts will be used for isolating purposes for the entire infected district and afterward destroyed. The Spanish hospital, well constructed and fairly well supplied, was seized and the goods confiscated for the use of the medical depart-

ment. The building is not used yet on account of infection, but is recommended as a general hospital for troops stationed on the north coast of Cuba. It is believed that the city of Gibara will become a health resort when the epidemic of smallpox now in existence there shall have been controlled.

Holguin, the principal city of the district, is similarly infected, and in much worse degree, there being in that town of 10,000 inhabitants, 800 cases of smallpox at the present time, and a correspondingly large number of cases of dysentery, typhoid fever and malaria cases. All civil government has been abandoned in this city, and its sanitary condition can be judged from the fact that 12,000 Spanish soldiers occupying the city have not established privy sinks. The situation in this district is grave and demands prompt and efficient action. The absolute necessities are: thorough isolation of patients and suspects; disinfection of infected foci; quarantine against infected adjacent districts; maritime quarantine; abundant disinfectants; medical supplies; rations for Cuban poor; 1000 cots with sheets, pillows, blankets, etc.; vaccine lymph for vaccinating 10,000 inhabitants; an efficient corps of physicians as a vaccinating and disinfecting committee, and a sanitary corps of civilian employes for thoroughly policing the city.

It is believed that with proper support, the situation in Gibara can be controlled in one month; in Holguin in two months and in the whole district in three months.

On October 29 I proceeded on horseback to inspect the sanitary conditions of the various hamlets along the line of the Holguin and Gibara railroad between these two cities. Parenthetically I will remark that there was an excellent dirt road and a beautiful open, fertile country.

Bahia de Río Blanco, a small hamlet, 30 thatched huts, 200 inhabitants, six miles from Gibara. No smallpox, the disease having exhausted itself; all huts infected.

Arroyo Blanco, eight miles from Gibara, 300 inhabitants. No smallpox at present; 100 cases in past year, with many deaths; all huts infected.

Cantimplora, five miles from Gibara, a town of 600 people. No smallpox, the inhabitants having exercised some precautions against the disease.

Tondinga, 500 inhabitants, ten miles from Gibara. No smallpox in town at present. No history of past epidemic obtainable.

Auras, twelve miles from Gibara, a town of 1000, at present occupied by Spanish soldiers, contained many cases of smallpox of virulent type.

Aguas Claras was next inspected as a probable location for troops, four miles from Holguin, at present occupied by Spanish soldiers. Water-supply very deficient; there were many cases of smallpox; all huts infected; locality as a probable camp site abandoned.

It is advised, first, that the remaining six companies of the Second U. S. Vol. Infantry be temporarily withheld from entering infected districts; second, that the six companies now in Gibara be held in quarantine at that point and that they do not proceed as yet to Holguin.

Having done everything in the premises with the means at hand, I next inspected Sagua de Tanamo. The latter town is somewhat inaccessible, necessitating twelve miles of travel in a row-boat to the landing, Esteron, at head of Sagua de Tanamo Bay; then ten miles on horseback to the city of Sagua. At Es-

teron is located the commissary store-house, under guard of three men. It is a filthy little hamlet of 300 inhabitants, where malarial fever is rife. All men who have been on duty at this place are invariably afflicted with malarial fever. I would recommend that these stores be moved up to Sagua with the company on duty there, to avoid the necessity of the above exposure. The road from Esteron to Sagua is in good condition. Basan, a small hamlet of 250 inhabitants, half-way to Sagua, is a healthy little town, containing no smallpox nor malaria.

Sagua de Tanamo, a town of 2500 inhabitants, situated on a high, well-drained hill, in the midst of a large, fertile valley, now under cultivation, giving the best evidence yet seen of marked regeneration from the effects of the war, is a comparatively healthy town. The water-supply is taken from the Sagua River, a clear, bold stream, running through the valley. The town is garrisoned by Company L, Third U. S. V. Infantry, under command of Major M. W. Harris, of that regiment. Acting Asst.-Surgeon W. H. Reynolds, in charge of the medical department, a faithful, hard-working, practical man, has established a good hospital in a rented building, where men receive careful professional attention. The general police of the camp is not good. All sinks were in an abominable condition, old sinks were not filled up and new sinks were not sunk beneath the level of the ground, but left to drain down into the adjacent valley, much to the detriment of the neighboring population. There were no kitchen sinks. No records have been kept of this hospital. The surgeon was instructed in military hygiene and hospital administration. The ration was complained of, as being deficient in fresh beef, and of proper diet for the sick.

At Sagua is located a 100-bed Spanish hospital, in fair state of preservation. The present occupancy of it was advised against, until thorough disinfection had been put into effect.

Baracoa was next visited—a town of 4000 inhabitants, garrisoned by three companies of the Third U. S. V. Infantry under command of Lieut.-Col. T. S. Wyly, who possesses all the requisites toward the making of an admirable soldier. The sanitary work that Colonel Wyly has done at Baracoa deserves special mention. He has moved his command from a well-selected camp-site into the Spanish hospital, situated on a high hill. All floors have been removed and earth taken away to the extent of two feet and refilled with fresh gravel, and covered over with a half-inch layer of concrete. Water-closets and shower-baths have been established. The water-supply is taken from the Baracoa waterworks, from the Macaguanigua River, piped up into a reservoir and distributed throughout the post. The hospital was in an excellent condition, records carefully kept, rations and cooking excellent; medical officers intelligent and energetic. A complete chemic laboratory of expensive instruments and rare chemicals was found. It is recommended that they be turned in to the U. S. general hospital, Santiago de Cuba, for the purpose of establishing a chemic laboratory at that institution.

Guantanamo was inspected, November 1. The headquarters and six companies of the Third U. S. V. Infantry were found encamped a short distance from the town of Guantanamo, the latter a city of 10,000 to 12,000 inhabitants. The camp was well selected, on a sloping hillside, well ditched and drained. All

privy and kitchen sinks were carefully dug and well policed. The sick report showed 25 per cent. sick, principal affection being malarial fever. The yellow fever outbreak has ceased to exist, no cases being found by the inspector. The water-supply, taken from the Guantanamo River, pumped into a reservoir, an iron tank, is there piped into a large iron cauldron and boiled. General police at camp is excellent. The hospital is carefully constructed and was found to be in excellent condition. The records were carelessly and improperly kept.

The following general impressions have been gathered from these and former inspections:

1. The lack of a hospital corps detachment at most of the regiments.
2. The inefficiency and ignorance of hospital stewards as regards their duties as such.
3. The low grade of the average medical officer, both commissioned and contract, especially the latter.
4. The fact that commanding officers, as a rule, are very much alive to the necessity of rigid sanitary precautions in this climate.

Upon arrival I was ordered to return at once to Holguin and Gibara and to assume entire control of the sanitary administration of the district. The below mentioned able corps of acting assistant-surgeons were ordered to report to me for duty in connection with the work of eradicating the disease: Myer Herman of New Orleans; Guel Dolz of Havana; W. O. Stone of Mississippi; Felipe Veranes, chief surgeon Cuban Army; Vicente Gomez of New York. We now have the city of Gibara under control and are at work upon Holguin.

SOCIETY PROCEEDINGS.

Southern Surgical and Gynecological Association.

Eleventh Annual Meeting, Dec. 6-8, 1898.

Dr. RICHARD DOUGLAS of Nashville, Tenn., presided over the meeting, which was held at the Gayoso Hotel, Memphis, Tenn.

Prayer was offered by Bishop Gailor.

Dr. ALEXANDER ERSKINE of Memphis delivered an "Address of Welcome" on behalf of the local profession, which was responded to by President Douglas, after which routine business was disposed of.

D. WILLIAM E. PARKER of New Orleans, La., presented a paper entitled

GUNSHOT WOUNDS.

He described the hospital conditions in Cuba and the wounds seen by him made by the modern bullet. He spoke of some experiments made under the direction of Major L. A. La Garde, surgeon U. S. A., as to the relative penetrating powers of the Mauser, Krag-Jorgensen and Springfield rifles. With ammunition of the years 1896 and 1897 the Mauser, fired at a distance of three feet from the muzzle into seasoned yellow pine posts, would penetrate 34 + inches; with ammunition of 1895 it would penetrate 32 + inches; with ammunition of the past year, the Krag Jorgensen, fired at the same distance, would penetrate 24 + inches, and the Springfield would penetrate but 5 inches; yet many lodged Mausers were found, and he was told by the Spanish chief surgeon that but six lodged Krag-Jorgensen were found by them. In speaking of wounds of special regions, he said that flesh wounds, as a rule, healed under one dressing. In the few cases that did not, the sloughing was at the points of entrance and exit, and not along the whole track of the bullet. Explosive effects were not seen by any of the surgeons. He stated that he had hoped to present some statistics as to the wounds of the war, but they could not be had. Wounds of the brain did well. He had heard of at least five cases that were still alive and doing well. But one case of wound of the spinal cord was operated upon and he was doing well. This patient had paralysis of both legs and of the bladder and rectum. Some spiculae of bone had been removed from the cord. At this time the

patient has perfect use of the right leg and partial use of the left, and has perfect control of his bladder and rectum. He said that while he had not in any way modified his opinion that laparotomy should be done for abdominal wounds in civil life, with the small modern bullet and lack of proper facilities this operation should not be attempted in the field, unless there should be symptoms of hemorrhage. About 50 per cent. of these cases recovered without operation. Chest wounds did well and caused but little trouble. In cases of wounded vessels, hemorrhage did not seem greater than in cases wounded by other bullets. When nerves were injured, nerve suture was not attempted on account of the rush of work, but he thought it should be attempted as soon as possible. None of the hospitals had a sufficiently large number of surgeons or hospital corps men, but he spoke of the efficiency of those who were there.

Dr. F. W. McRAE of Atlanta, Ga., followed with a paper on
PENETRATING WOUNDS OF THE ABDOMEN, WITH REPORTS OF CASES.

At the outset, the essayist referred to a resolution passed unanimously by the Association at the Nashville meeting in 1896, to the effect that in all cases of penetrating wounds of the abdomen it is the duty of the surgeon to make an exploratory incision so as to definitely determine whether the viscera have been injured or not. Since then a few able surgeons have dissented from this opinion. The propriety of surgical interference in cases of penetrating gunshot wounds of the abdomen will depend on one of three things: 1, the general condition of the patient; 2, dangerous internal hemorrhage; 3, wounds of the stomach or intestines large enough to permit extravasation. He quoted from contributions to this subject by Senn, Nunez, Winslow, Budinger, Vaughan, Woolsey, Robson, Chauvel, Michaux, Klemm, and others, and said, from the conflict of opinion and advice given by these and various other surgeons, one is at a loss to know just how to proceed in many cases. His own convictions, based on sixteen cases, which he narrated, are positive. While he has the greatest admiration and respect for the surgical opinions of Senn, he should be recreant to his convictions were he to accept the proposition of non-interference laid down by Senn in his recent contributions to the subject. In most of the cases which have come under his observation where grave lesions of the abdominal viscera have existed, the symptoms of internal injury were practically *nil*, and the positive signs of grave damage almost entirely absent. In conclusion, he reiterated his firm conviction that every case of penetrating wound of the abdomen, where there is reasonable doubt as to injury of the abdominal viscera, should be subjected to at least an exploratory operation. This enables the surgeon to either absolutely be sure that no injury has been done to the viscera, or to repair, as far as possible, such injuries when they exist. The mortality following a simple exploratory operation *per se* is so small as not to weigh against the much greater mortality that necessarily follows the expectant plan of treatment. In the cases he had seen, the general and local signs have been so misleading and enigmatic that prior to the operation a conclusion on his part as to internal conditions would have been entirely guess-work.

Dr. HORACE H. GRANT of Louisville, Ky., contributed a paper on

PRACTICAL MANAGEMENT OF BULLET WOUNDS OF THE ABDOMINAL VISCERA.

Observation and experience with operators coming frequently in contact with this lesion have determined that penetrating wounds of the abdomen demand laparotomy at the earliest possible moment after diagnosis and thorough inspection of the entire region endangered. It is established that not only is the mortality in untreated wounds of the abdomen almost 100 per cent. where the intestines are perforated, and very high in wounds of the solid viscera, but it becomes less promising every advancing hour, until by the second day peritonitis sets in and destroys the hopefulness of the prospect. Within the past two years the speaker has operated upon four cases. In each case the patient was seen early, in no instance later than four hours. In three, resection of the intestine was necessary. Three of these patients recovered; the fourth died from septic peritonitis due to the escape of a large quantity of fecal matter before operation. Autopsy disclosed a perfect intestine.

These three papers were discussed together.

Dr. W. L. ROBINSON of Danville, Va., said he had seen a good many cases of gunshot wounds of the abdomen, and nearly all of them died, either with or without operation. Early operative interference might save some of them.

Dr. G. S. BROWN of Birmingham said he knew of several cases of gunshot wounds of the abdomen that occurred in and

around Birmingham, that recovered without operation. Personally, he had operated on five cases, one of which recovered. In this case there was no perforation of the intestine. Undoubtedly, diarrhea and starvation, mentioned by Dr. Parker in his paper, have something to do with the favorable results. The intestines are most liable to be perforated when full.

Dr. WILLIS F. WESTMORELAND of Atlanta said the results of gunshot wounds of the abdomen on the battle-field should not be compared with those met with in civil life. It is not a question of operating, so far as fatal results are concerned, but the manner in which the operation is done.

Dr. W. E. B. DAVIS of Birmingham thought that Dr. Parker's paper was not an argument against operative procedures for abdominal wounds. Surgeons on the battle-field do not have the same facilities for operating on penetrating wounds of the abdomen that they do in civil practice, and which are necessary for the proper care of cases. If a man sustains an injury to the intestine, if his abdomen is not opened, death may be expected. In twenty or more cases operated on by him and his brother, all of the cases died that were seen twenty-four hours after the injury. This is not an argument against operative interference, but against late operation. Statistics impress surgeons with the importance of early operation.

Dr. GEORGE A. BAXTER of Chattanooga believes it is not necessary in many instances to open the abdomen in cases of gunshot wounds, and cited a number of cases that recovered without operative interference.

Dr. JOHN T. WILSON of Sherman, Texas, advocated early operation in cases where the surgeon is convinced that perforation has taken place. The character, technique and rapidity of the operation are very important. In operating, the intestines should be exposed as little as possible.

Dr. W. L. RODMAN of Louisville said that while he has pursued the practice of operating on penetrating gunshot wounds of the abdomen for the last ten years, after hearing the paper of Dr. Parker and reading the recent contributions of Senn and others, he wondered whether he as well as other surgeons may not have gone too far in operating in so many of these cases; at the same time, he does not wish to be understood as advising a masterly inactivity where the environments for operative interference are favorable.

Dr. WESTMORELAND said that, given a case of perforation of the intestine, particularly where there is extravasation of contents, instead of being masterly inactivity, it is criminal inactivity for a surgeon not to operate.

Dr. PARKER, in closing the discussion on his part, said that he had tried to make a clear distinction between the plan of treatment of gunshot wounds of the abdomen met with on the battle-field and those encountered in civil life. He is strongly opposed to laparotomy on the battle field on account of the conditions that exist. In civil life, however, the thing to do in cases of gunshot wounds of the abdomen, is to get in and out of the belly as soon as possible consistent with good work.

Dr. McRAE believes that a large proportion of operations undertaken for gunshot wounds of the abdomen late will terminate fatally.

Dr. GRANT stated that practically all cases operated on after twenty four hours perish. It is impossible to diagnosticate perforation of the intestines with any degree of certainty. If a patient is seen within eight or ten hours after the receipt of a gunshot wound of the abdomen under favorable surroundings, whether the bullet has penetrated the intestine or not, the skillful surgeon will not hesitate to make at least an exploratory operation, because it would not hurt the patient, but would probably save his life.

Dr. W. D. HAGGARD, Jr., of Nashville, Tenn., read a paper entitled

A PLEA FOR THE MORE CORRECT APPLICATION OF THE EMMET METHODS IN PLASTIC SURGERY.

The pioneer work of Sims was feelingly referred to. It was a unique circumstance in the annals of surgery that the instruments which made the feat of Emmet possible, and the fundamental principles of his success have remained unchanged. It is not so much the truth of homage to unprecedented genius, as the truth of the great principles enunciated, and the perfection of his devices. The extension of the method of Sims in fistula to the injuries of the adjacent soft parts was made by Emmet. The evolution and perfection of the operation on the cervix was traced. Dr. Haggard described the mechanics of the production of rectocele associated with the common transverse tear of the posterior vaginal wall involving the pelvic fascia, which is the essential pathology of this injury. The rational correction of this complex condition then would not be not to sew the labia together, which is the popular procedure

in one class of operations, nor to denude an arbitrary area of fanciful shape on the rectocele and bring the edges of the raw patch together, after the fashion of another class. It would rather be, in the language of Emmet, "catch up the retracted pelvic fascia at such a point and in such a manner as to take in the slack, as it were, of the fascia throughout the pelvis. By this procedure the displaced posterior vaginal wall is certainly lifted up and drawn forward in contact with the vesicovaginal septum. As the steps of the operation advance the displaced anus is lifted upward and forward, the everted tissues at the vaginal outlet gradually rolled in and the separated levator ani muscles brought together. He accentuated the essential features in detail. The classic operation for the complex tear of the perineum is more amenable to pictorial description and he believes it is more generally understood. He minutely depicted it. In every branch of art there is a troop of imitators who follow so closely the hall-marks of the original that the specimens can scarcely be distinguished from the genuine. So closely are mannerisms copied in literature, art, sculpture and the drama, that the imitators create a distinctive school. This accuracy of duplication is rendered possible by the faithful and scrutinizing study of the original pattern. The unlimited opportunities for the study of models in the arts are obviously impracticable in plastic surgery. We can not all have the privilege of seeing the peerless Emmet, although a distinguished fellow of this Association says that everyone who aspires to do this work ought to. Dr. Haggard regrets that many of Dr. Emmet's pupils do not or can not copy his methods, and he does not hesitate to say that those who do conscientiously strive to imitate him, fall very short in their efforts, but they have at least the satisfaction of having a correct conception of the highest ideals in surgery.

Dr. HOWARD A. KELLY of Baltimore, Md., presented a paper entitled

THE TREATMENT OF COMPLETE RUPTURE OF THE PERINEUM BY DISSECTING OUT THE SPHINCTER MUSCLE AND ITS DIRECT UNION BY BURIED SUTURES.

He said that the results of the best methods of the treatment of complete tears of the perineum are not entirely satisfactory in a large percentage of cases. The control over liquid motions and flatus is as a rule not secured immediately, and it is usually necessary to encourage the patient by telling her that she "will have to learn to control the muscle in the course of time." Such a control, more or less perfect, is gained in the course of several months. This defect in our present procedures is due to a faulty approximation of the sphincter ends which lie buried in a pit, and are therefore difficult to bring into accurate, firm apposition by sutures embracing a considerable quantity of tissue surrounding the sphincter ends. Dr. Kelly proposes, therefore, the deliberate dissection and freeing of the sphincter ends, drawing them out about one and a half centimeters from the tissues, cutting off the scarred ends, and affecting a direct union of the freshened ends by two or three catgut sutures. He was led to do this operation by his experience in a case which had been operated upon six times with a result, which, judged by superficial appearances, was perfect, and yet the patient had no control over her bowel functions. He made a semi lunar incision around the anterior periphery of the anus and found the right sphincter end buried in scar tissue in the median line, while that of the left side was ectopic and attached out under the ischial tuberosity. The sphincter ends were united directly by buried catgut sutures, and the skin wound closed and union took place *per primam*. In addition to these buried catgut sutures a splinting suture of silkworm gut is passed through the middle of the sphincter near the edges of the wound and on up through the septum splinting the ends together and taking the tension off the catgut. He has since taken the hint given by this case and adopted a similar procedure in six cases of complete tear of the perineum due to confinement. Two additional cases were operated upon by Dr. W. W. Russell and one by Dr. Ramsay. In each instance there was a surprising difference between the new and older methods, noted at once in the earliest stages of the convalescence, and the patient was immediately conscious of perfect control of her functions. The bowels should never be locked up. Great care must be taken not to leave any dead spaces in closing the remainder of the wound in the usual way, in order to avoid all risk of infecting the buried sutures. He only recommends this operation to those who possess considerable skill in doing plastic operations and in securing a snug, accurate adaptation of the parts.

In the discussion Drs. George H. Noble of Atlanta and J. Wesley Bovee of Washington, D. C., added their testimony to the usefulness of the method described by Dr. Kelly, but certain features of the technique of which they modified,

Dr. LEWIS S. McMURTRY of Louisville, Ky., read a paper on
THE TREATMENT OF CANCER OF THE UTERUS.

He said that the treatment of uterine cancer had not shared proportionately in the great advance of modern pelvic surgery. While other diseases which were long the opprobria of medical and surgical science and art had been made amenable to surgical treatment, the treatment of cancer of the uterus was practically where it was twenty years ago. Cancer of the uterus was a very common disease. Women were more subject to cancer than men and in quite one-third of all cases of cancer in women, the uterus was the seat of the disease. The disease occurred as a rule between the ages of 30 and 50, attaining its maximum prevalence at the menopause. It was rare in unmarried and sterile women, and was most common with the mothers of large families. Race and environment have much to do with its development. It had been the experience of the essayist that the disease is proportionately rare in the negro race. From a careful statistic study, Billings declares that cancer is slowly but steadily on the increase, and that its greatest prevalence is in nations which have attained the highest state of civilization. In 1893 London alone lost 3412 of her population from this disease, a percentage of 3.73 of the total death-rate for the year. Cancer of the corpus uteri is rare in comparison with the common exhibition of the disease in the cervix, but not so uncommon as was formerly understood. Cancer of the cervix originates: 1, in the squamous epithelium of the vaginal portion of the cervix; 2, in the cylindric epithelium of the cervical mucosa, and 3, in the epithelial lining of the cervical glands. Cancer of the body of the uterus originates in the epithelial structures of the endometrium. The treatment of uterine cancer consists in a variety of operative procedures, leading up to the most recent operation of combined abdominal and vaginal extirpation. The names of Verneuil, Carl Braun, Schroeder, Pawlik, Koerberle and Byrne are associated with high amputation of the cervix with ecraseur, cautery and knife. High amputation, as practiced by Schroeder, attained the greatest favor and maintained its position over hysterectomy until 1886. Prior to this time, hysterectomy had such a high mortality (15 per cent.) that high amputation deserved preference. In 1886 the operation of total vaginal extirpation was revived by Martin, Leopold and Olshausen. Since that time this operation has been very generally adopted, and is today the accepted treatment for the radical cure of cancer limited to the uterus itself. With the modern perfected technique the mortality of this operation is reduced to about 4 per cent.

The Doctor referred to the statistics of vaginal hysterectomy as given by Pozzi in the third edition of his treatise on gynecology, an analysis of which does not strengthen or inspire confidence in the ultimate results of this procedure. He said that claims are being made for the permanent cure of uterine cancer by hysterectomy which could not be realized. Of all the cases of uterine cancer which apply for treatment, only a small proportion are within the scope of a clean extirpation by vaginal hysterectomy. The large number of cases in which the disease recurs at the site of operation within a few weeks demonstrates that the operation is in most cases simply a resection, leaving behind sufficient disease for continued activity. His personal experience with this operation has been discouraging. Vaginal hysterectomy for cancer has never been a favored operation with him. During the past year he has done the operation in five cases, which were selected as most favorable for permanent cure. In all the disease was discovered early, and, so far as macroscopic evidence could show, it was limited to the uterus itself. The organ was normally mobile. Of these five cases treated by vaginal hysterectomy, two had recurrence, one in the bladder, the other in the vaginal fornix at the cicatrix, within five months after operation. These were selected cases in which the disease was early recognized; the patients were under 50 years of age and well nourished. The operation was done with a view of going far beyond the region of probable infiltration, and removing the appendages with the uterus. Based on his own previous experience, and that of other operators, it is doubtful if one of the three remaining cases will be living at the end of three years from the time of operation.

The histologic structure of the uterus and adjacent structures is exceptionally favorable for disseminating this disease. The rich lymphatic distribution here is an active means of infection, but the studies of Cullen show that the activity of lymphatic invasion has been exaggerated, and that the common mode of infection is along continuous structures. Extension is most rapid around the vaginal vault, forward and downward under the bladder, and in the base of the broad ligaments. The common invasion of the vagina by implantation

about the cancerous cervix has suggested to Werder the method he has practiced of total excision of the uterus and vagina by suprapubic operation.

In conclusion, Dr. McMurry considered in detail the choice of operation for the several classes of cases of carcinoma of the uterus which are presented to the surgeon for treatment. For advanced cases, where the entire field of evident invasion cannot be removed, he advocated thorough curettage, scraping away necrosed tissue, emptying obstructed pus accumulations, washing out debris and establishing drainage and antiseptics. Such local treatment will reduce septic intoxication, prolong life, and promote comfort. All operations for radical cure should be limited to cases in which the disease is recognized sufficiently early for thorough removal of invaded structures. This will be best accomplished in the majority of cases by abdominal section and removal of uterus from above, including liberal portions of adjacent structures, especially the upper portion of the vagina, where implantation from the cervix is so often found. While liberal excision of suspicious areas of tissue should be done, it will rarely be found necessary to remove the subperitoneal lymphatic glands, since their enlargement has been often found inflammatory in character instead of cancerous. The field of vaginal hysterectomy should be limited to the few cases of early diagnosis in which operation can be done before deep extension of the disease. Efforts for prophylaxis should be most diligent and should be of universal application. All ulcerative and cicatricial lacerations of the cervix should be repaired as a prophylactic measure.

Dr. WILLIAM L. RODMAN of Louisville asked the members to give their experience relative to the frequency of cancer in the black and white races. He was rather surprised to hear of the infrequency of the disease in the negro woman. According to the last census statistics of Billings, cancer of the uterus is more common at all ages in the black than in the white race. This is also the experience of Matas, who has examined the records at the Charity Hospital in New Orleans. An examination of all deaths recorded by the Health Department of Louisville for the past thirty years corroborated the same view.

Dr. ERNEST S. LEWIS of New Orleans stated that while he had not observed a very marked difference in the relative immunity of negro women to cancer of the uterus, still if his experience is not at fault, he thinks, owing to their uncleanness, their mode of living, and to the more frequent accidents to which they are subject during labor, they are particularly prone to cancer of the uterus. With regard to the results of all operations for cancer of the uterus, he endorsed everything Dr. McMurry had said. He could only recall one case of vaginal hysterectomy for cancer that lived for eight years, after which the disease returned, and the patient finally died. The disease is so liable to return that he considers any operation as palliative, and he believes that would be the result of the abdominal operation advocated by Dr. McMurry, particularly in advanced cases, and if cases are met with in the incipency of the disease, in his opinion as much could be accomplished by the vaginal as by the abdominal operation.

Dr. VIRGIL HARDON of Atlanta said during his seven years' connection with the Grady Hospital, he had reason to believe that cancer of the uterus was more frequent in negro women than in white women. He has been led by his experience in the treatment of uterine cancer to the same conclusion as that reached by the essayist, except he had been led to go further. He has operated for cancer of the womb by vaginal extirpation, by the abdominal method, and by the combined method, and he has never yet operated upon a case where recurrence did not take place sooner or later, and for this reason he has lost all confidence in operative measures as a means of effecting a permanent cure. However, he has no doubt on theoretical grounds, that if cases are seen sufficiently early, a permanent cure might be effected by surgical interference.

Dr. HOWARD A. KELLY of Baltimore remarked that he was astounded at the trend the discussion had taken, because he had seen dozens of cases of cancer of the uterus that had remained well for a number of years after having undergone surgical intervention, removing the uterus either by vagina or by the abdomen. He finds carcinomas of the uterus as frequently in negroes as in white women.

Dr. J. WESLEY BOVIE of Washington, D. C., said that his experience in the radical treatment of cancer of the uterus has been more satisfactory than what he had been hearing today. He knows of a good many cases upon which he has operated that have gone on for three years or more without a recurrence of the disease. He has done three operations after the manner described by Werder in the *American Journal of Obstetrics*, last winter, and he is much pleased. In each case he adopted the abdominal rather than the vaginal route, believing a more

radical operation could be performed by this method. He has great hopes for the future treatment of cancer of the uterus by complete abdominal hysterectomy, undertaken early.

Dr. WILLIAM L. ROBINSON of Danville said that when the parts have become infected beyond the uterus, no dissection, however extensive, would ever remove the cause. When the disease has extended beyond the uterus, he believes it is beyond the power of any surgeon to thoroughly remove it. Therefore, unless an operation could be done very early, he would not advise the removal of the uterus.

Dr. W. E. B. DAVIS was profoundly impressed with the position taken by Dr. Lewis as to the ultimate outcome of cases of cancer of the uterus, believing his position is correct. There is no man in America who has had a larger experience in the treatment of cancer of the uterus than Dr. Lewis of New Orleans, and the profession were familiar with his great skill as a surgeon, hence his experience regarding uterine cancer was certainly valuable.

Dr. McMURTRY, in closing the discussion, said he could not endorse the view that Dr. Kelly takes with reference to the ultimate results of the operative treatment of cancer of the uterus. He knows that Kelly's work in this direction has been extensive, and that his reports are sincere and reliable, but there are a great many surgeons, working in the same line, who have done thorough, faithful, skilful work in the radical treatment of uterine cancer, who doubt the future confirmation of Dr. Kelly's views.

Dr. JOHN T. WILSON of Sherman, Texas, read a paper on

FRACTURES INVOLVING THE ELBOW-JOINT.

He said: Fractures involving the elbow-joint are of great interest and always cause more or less anxiety because of their liability to ankylosis, partial or complete: to deformity, or to some interference with the perfect function of the joint as a result. Fractures without the capsular ligament are not so grave, are under better control, give more satisfactory results, and cause less apprehension. Fractures within the ligaments are always troublesome, give rise to more inflammation, demand greater care in their reduction, in the dressing, and in the after-treatment. Ankylosis in various degrees is generally looked for when union has taken place; it is extremely difficult in many cases to avoid this result, but with care, patience and perseverance on the part of the surgeon and patient, this complication can be remedied wholly or in part in nearly all cases. It is necessary to remember that the muscular attachments to the region around the joint are very great. It is difficult to conceive of a fracture here where the fragments do not involve a muscular attachment, and are more or less displaced by it. A knowledge of these attachments is sufficient to indicate the difficulty of confining the broken bones in perfect apposition. In fractures of this joint there is usually considerable inflammation ensuing, the cartilage of the articular surfaces being wounded and the investing ligaments lacerated. The amount of callus thrown out is considerable, it hinders motion, and is generally slow of absorption.

To get the best practical results in these fractures it is of supreme importance to keep the parts at absolute rest. To do this, the joint must be put up in a suitable fixation dressing and patient kept in a quiescent state; in order to do this it is necessary to confine patient to bed for a week or more, and a fixation dressing is applied in the beginning of the treatment. Eminent surgeons differ in regard to the position of the forearm. The different fractures and the different degrees of fracture require different positions of the forearm, require different positions in pronation, supination and the angles. Either extreme strikes him as being irrational. He is guided by that position which favors best the coaptation of the fragments and the relaxation of the muscles, giving the least deformity, and the flexed position in some degree has been the one usually employed. After an aseptic scrubbing of the joint, arm and forearm, under an anesthetic the diagnosis is made, if possible, and the dressing applied. After a nice application of the spiral reversed roller, not too tight, a firm pad of sterilized gauze is placed in front of the joint opposite the broken fragments, thick enough for a firm support, and not as thick as to interfere with the functions of the splint. The anterior splint is then put in place, one with a ratched hinge much like that of Dr. Agnew, which can be placed at any angle desired and extending from near the wrist to above the insertion of the deltoid. A pasteboard trough is then moulded to the posterior surface of the limb extending from the axilla to the ends of the fingers and confined by a roller. If no contraindication this dressing is not disturbed for three or four days, or longer, if deemed advisable; it is then carefully removed, the joint examined and if the inflammation has subsided the permanent dressing is applied.

The correct position is maintained by the anterior splint and a carefully moulded plaster of paris trough is fitted posteriorly; this must be adjusted nicely in order to support the fragments, keeping them in place posteriorly and laterally. This should also extend from the axilla and support the hand, should not be heavy and cumbersome, but firm enough to thoroughly fix the joint and arm. This can be done by having some strips of heavy gauze or cheese cloth measured by the sound arm and carefully cut to the proper size; the plaster is thoroughly rubbed in these and they are then applied, the arm being well protected, layer by layer, a solution of plaster rubbed in between each layer until of the thickness desired. This dressing can be controlled at will, and if nicely applied is not so cumbersome as it would seem. If it becomes desirable to change the position or angle, the plaster trough can be taken off by simply removing the roller, the position changed and a new trough applied. He prefers to have the anterior splint of wood broad enough to cover the joint, and yet not extending quite to the ends of the epicondyles, the joint fitting closely down to the bend of the elbow, the ratched notches changing not more than the eighth of an inch at each movement. If properly made, this splint is light enough and yet firm enough for all practical purposes, and much of its usefulness depends upon its fitting well, and so with the plaster trough. If extension and counter-extension are necessary, these can be had by extending the plaster trough under the axilla and the anterior splint will make sufficient counter-pressure by means of the roller. This gives a firm, fixed dressing, keeping the parts in place and at rest, so necessary in all inflammatory conditions of the joints. The patient is seen frequently, the joint examined at any time when there seems to be an indication for it; this should never be done, however, if there is no special indication for it after the permanent dressing has been applied and the surgeon satisfied that the fragments are in place. If kept in this position and joint at complete rest, danger of ankylosis is not great.

After three or four weeks, not earlier unless there is special indication for it, dressings can be renewed, the joint examined with care and, if any stiffness, passive motion gently instituted under an anesthetic, if necessary. If only fibrous bands exist, they can be broken up. Violence should not be used. Gentle motion, frequently repeated and persevered in, will often accomplish more than sudden forcible separation with shock attending it. Rubbing and systematic massage at this stage is of great value, and if stiffness is not readily overcome, persistence in the gentle efforts continued; after five or six weeks patient is instructed to gently exercise the joint twice daily with Indian clubs and dumb-bells, neither of which should be too heavy. He is advised to use the hand and arm constantly, and in time, in the great majority of cases, will be rewarded with success. In some cases improvement may take many months or two or three years before the function is restored. If there are several fragments of bone and some so small they can not be kept in apposition, their removal would save time and trouble and give a more favorable chance for a better joint. If ankylosis has supervened upon a fracture and many months of patient effort at restoring the function of the joint proved futile, an operation is justified. If a fragment is causing the trouble, it can be removed. A resection will often give a good useful joint.

Dr. J. WESLEY BOVEE of Washington, D. C., read a paper entitled

THE USE AND ABUSE OF NORMAL SALT SOLUTION.

The term "normal salt solution" has been used interchangeably with artificial serum. Various compositions and strengths of the constituent elements of the blood have been used with the name—normal salt solution. According to Kirke's "Hand-Book of Physiology," salt exists in the blood plasma in the proportion of 5.546 parts per 1000 and .6 per cent. is a good practical formula. Other ingredients, i. e., egg albumin, have been added to the salt which really make an artificial serum instead of normal salt solution. Of the five different routes through which it is introduced, the intra-arterial, suggested by Dawbarn, is considered unsafe in all conditions and should not be practiced. The subcutaneous is the most useful for general use. In emergency work the intravenous method will often be needed in severe hemorrhage and the rectal enema of solution will be found of great advantage in nearly all cases where no bowel lesion is to be combated. In abdominal surgery the peritoneal cavity will be the place selected for its introduction, and even in vaginal opening of the peritoneal cavity as in hysterectomy from this way the author has thrown considerable quantities into the peritoneal cavity, the hips being elevated at the time and the peritoneal opening closed directly afterward. The intravenous route, usually the most

rapid, may be rendered slower than the subcutaneous by difficulty of finding a vein and successfully introducing the canula. The physiologic action of normal salt solution is as a powerful stimulant to the cardiac ganglia and the nerve-centers. The skin, kidney and intestinal functions are stimulated markedly and other organs are likewise affected. Osmosis is markedly promoted by it and as a result of increased arterial tension the blood supply to the heart muscle is much increased. It has a hemostatic effect when supplied locally to raw surfaces, lessening oozing by stimulating and contracting the smaller vessels. According to Hayem and others, it augments the number of red-blood corpuscles. It is eliminated by the skin, changing the chemic reaction of the perspiration and heavily loading it with salt. The kidneys also carry away an enormous amount of it when large quantities of it have been introduced into the tissues. The lungs remove it freely, it having been noticed in crystals on the lips after its free use. Autopsies after its use under the skin have shown a considerable quantity of it in the intestines, demonstrating it is thrown off by this route.

The essayist then spoke of its use in general medicine. In surgery the principal indications for its use are shock, hemorrhage and sepsis. In shock it should be employed early, on the table during operations, or even before the operation has been undertaken in bad cases, or after operation in milder ones. Severe hemorrhage is to be treated in the same manner, though only after the flow of blood has been checked. If the hemorrhage be severe, the intravenous route may be employed, it being about the only indication for this method. In the author's abdominal work he almost invariably leaves a considerable quantity of salt solution in the peritoneal cavity. Its salutary effect is produced by its action on the abdominal viscera with which it comes in close contact. To prevent adhesions in the pelvis, one or two liters suffice. It hastens absorption of stray or concealed blood-clots, septic foci, or escaped fluids, by carrying them well up into the abdominal cavity in cases of pelvic surgery. In hemorrhage it is probably best to infuse small quantities and often rather than one large quantity. Judging from the reports of experimenters, the use of salt solution is not a harmless procedure. It is contra indicated in such conditions of the blood as hemophilia, dyscrasias, deficient fibrin, etc. It would seem not unreasonable that such a strong stimulant coupled with its dilation of the blood vessels, when used in large quantities, and especially when thrown directly into them, would be very harmful in such conditions of the circulatory apparatus, as myocarditis, pericardial effusion, atheroma, arteriosclerosis, cardiac degeneration, bad valvular lesions, thrombosis, and recent cerebral apoplexies. Chronic diseases of the lungs, kidneys or liver, especially if malignant, are apt to be aggravated by it. Active hemorrhage in any location is aggravated by it. The presence of toxins in the blood has been found to retard the elimination of normal salt solution, and for that reason small quantities at a time only should be employed.

It is necessary to avoid certain accidents and mistakes in using normal salt solution. We must know the solution is sterile when it enters the tissues of the body, except by the rectum, in which case it is of no moment. Avoid air-bubbles entering into blood-vessels or cellular tissue. The fluid must be of sufficiently high temperature when it reaches the body. Chills occur from a cold solution and are dangerous to very weak patients. The vessel containing the solution as well as the tube and needle conducting it must be aseptic and thoroughly pervious; the tube should have a glass window that the rapidity of the current and the presence of any foreign body may be noticed. When the solution is to be introduced through the skin, either into cellular tissue or vein, the local surface should be cleaned as much as the limited time will permit. Probably not more than a half liter should be injected into the tissue through one puncture, as localized necrosis and aseptic inflammation have resulted from over distention of the tissue spaces. Ordinarily not more than one ounce per minute should be injected into tissue or vein. Pulmonary edema, dyspnea, headache, vertigo, mental excitement, delirium, hallucinations and severe pain in the left side occur from over distention of veins from too large infusion.

In the discussion, Drs. Parker, Johnson, Noble, Farham, Cartledge, Tiffany, Kelly, McMurtry, Baxter, McRae, and Brown, spoke favorably of the use of normal salt solution.

Dr. JOSEPH TABOR JOHNSON of Washington, D. C., presented a paper on

THE CONSERVATIVE TREATMENT OF THE DISEASED OVARY.

The difference between the radical and conservative treatment of the diseased ovary is somewhat difficult to define, inasmuch as the most radical treatment under some circumstances is really the most conservative, while in other cases,

to conserve the best interests of some particular diseased ovary requires the most radical surgery.

In the early part of the present decade, quite a conservative wavelet swept over the country, and considerable harm was done to pelvic and abdominal surgery in the mild and gentle name of conservatism. Incomplete conservative operations were done, some of which had to be completed later on by radical operations. Some of the men who claimed to be the most conservative, and attracted the timid doctors and frightened patients, were actually removing more ovaries and tubes than many of their so-called radical friends. Much credit has been claimed for saving a part or the whole of one ovary and tube, when only a simple catarrhal salpingitis existed, by an operator posing before the profession and community as a conservative, when the surgeon designated a dangerous radical, to be avoided, would actually not have operated at all, and would probably have cured his patients by other means. In some instances genuine, successful conservatism was practiced with lasting beneficial results, but not always from the highest and purest motives. Again, it has been charged that actual radicalism has successfully masqueraded under the name and guise of conservatism to the injury of the trusting patient, and the discredit of good surgery. So much has been learned by accumulating experience, as the domain of the gynecologist has undergone so much expansion, that real conservatism is gradually gaining ground over real radicalism to such an extent that he who presents ovaries and tubes or a fibroid uterus to a modern up to date medical society, has to state very good reasons why he sacrificed these important organs in their entirety to escape criticism and possibly censure. Sacrificial surgery is gradually giving way to more conservative and humane methods. He believes there is a maxim in general surgery in favor of saving every inch of the human body possible, and another that it requires a higher order of skill to save a mutilated or diseased member than it does to cut it off or to cut it out. With his present experience in abdominal surgery, he is free to confess that he can now save ovaries and tubes which he formerly thought it necessary to totally remove. The increasing skill of our abdominal surgeons and their accumulating experience in actual conservative work, go to show that we are approaching nearer to that true conservatism which is the offspring of increased skill and experience. In abdominal surgery it requires a higher order of skill and a greater experience to save an organ or part of an organ than it does to remove it. It is important to save a portion of one ovary, when the other has been removed on account of a tumor, an abscess, or for any other cause. The disagreeable symptoms accompanying the artificial and premature change of life are often stormy and protracted; in some rare instances threatening, if not resulting in actual insanity. These women are happily prevented from falling into such a condition by saving one or a portion of one ovary; menstruation is then not interrupted, and the sexual and other feelings of the patient undergo none of those sudden and peculiar revulsions which unfortunately sometimes follow the total removal of both ovaries and tubes. In conclusion, Dr. Johnson said that if growing experiences in the abdominal cavity and accumulation of evidence continue in favor of more conservative and less sacrificial operative work, he feels sure that the deep debt of gratitude now felt toward abdominal surgeons by suffering women will be tenfold increased and intensified.

Dr. RICHARD DOUGLAS of Nashville, Tenn., delivered the presidential address. He made a departure from the usual or stereotyped address and selected for his subject

ACUTE GENERAL PERITONITIS.

Before considering his subject proper, he spoke of the growth of the association and the excellence of its scientific work, saying that the association owes its existence and high standing to the indefatigable efforts of Dr. W. E. B. Davis, the permanent secretary.

A bacteriologic classification of peritonitis is beset with many difficulties, and while the speaker is free to admit that for all practical purposes peritonitis is of bacterial origin, yet there occurs a respectable percentage of cases in which the most rigid examination fails to disclose the presence of micro organisms. Hartmann and Moreau recently reported such a case in detail. Of 110 cases bacteriologically classified by Flexner, there were twelve cases which he was obliged to consign to the idiopathic group. It is true that in all of these patients there existed conditions predisposing to peritonitis, such as cardiac, renal or hepatic disease. In the intensely septic mycotic form of peritonitis their absence may be accounted for by the fulminant type of the disease, death occurring from intoxication before the colonies of bacteria are well established.

Any effort to individualize the effect of a specific bacterium,

to connect its presence with a definite pathologic phenomenon and characteristic symptomatology is as yet futile. Mikulicz avers that all forms of peritonitis run the same clinical course regardless of the bacteria that cause it. There is a law laid down by Maloz to the effect that if the peritonitis is of intestinal origin, the colon bacillus will show it; if it is of uterine origin, that is, connected with abortions or labor, we will find the streptococcus. It is asserted that the colon bacillus constitutes nine-tenths of the bacteria of the digestive tract, the colon is its natural habitat, but its behavior upon gaining entrance to the peritoneal cavity depends upon many circumstances, and this bacillus has many morphologic conditions, many forms and stages. The constancy of its presence in peritonitis, since the demonstrations of Welch and others of its capacity of transmigration through the bowel, has led many to attach to it great significance as an etiologic factor, but its association with other forms of micro organisms renders the first proposition of Maloz null and void. If we interpret Maloz' law correctly, the absence of streptococci would eliminate the possibility of peritonitis being of puerperal origin. In rebuttal of this idea, Dr. Douglas quoted from Winckel, who says, "Kroenig examined all parts of the uterus of a woman dead from infection and found not only the superficial thrombi at the placental site thickly filled with bacteria, but also the serous lining of the peritoneum." This case shows that a woman may have a peritonitis following abortion without streptococci, and it further shows that the colon bacillus without an intestinal lesion may produce a fatal peritonitis. No doubt too much importance has been ascribed to the colon bacillus, and it is interesting to note that Tavel, who was among the first to emphasize the pathogenic powers of the bacillus coli communis, thinks now the bacillus coli should be considered merely a collective name of many varieties of bacteria.

No better argument against bacteriologic classification can be adduced than the words of Simon Flexner, who says: "In order that pathogenic bacteria introduced directly into the peritoneal cavity may cause a peritonitis, general or circumscribed, evanescent or fatal, the normal conditions of the peritoneum must in some way be modified." It is clear, then, that in the human being, as in experimental animals, some other condition than the mere presence of pathogenic micro organisms in the abdominal cavity is necessary in order that peritonitis may be produced. Bacteria alone and unaided by physical conditions are comparatively innocuous.

Restricting consideration entirely to acute general peritonitis, it occurs from traumatic or consecutive causes. Under the head of traumatic peritonitis is embraced all infective inflammations arising from wounds of the peritoneum, whether accidental or operative, penetrating or non penetrating. Consecutive, secondary or symptomatic peritonitis may be subdivided into peritonitis by continuity, and perforation peritonitis.

Under the head of traumatic peritonitis all forms of peritonitis must be embraced that are due primarily to a trauma. The destruction of tissue, the retention of blood clots and natural secretions, prepares a suitable soil for microbic invasion, and this essential infecting element may be introduced from without, as through penetrating gunshot, stab or operative wounds, under which circumstances it is usually a poly infection, the streptococcus predominating. There are also contusions of the abdomen without an external wound which so injure and lower the resistance of the tissue as to favor the migration of the intestinal micro organisms and their infection of the general cavity.

The supervention of acute general peritonitis, as secondary to pre-existing disease processes, embraces in its etiology infective inflammations not only of all intraperitoneal viscera, but all organs or tissues contiguous thereto, and it does not appear to him to be too broad, if there be included within its scope those peritonitides of hematogenous or metastatic origin, for it is well established that the specific germs of diphtheria, scarlet fever, pneumonia and erysipelas have produced acute general peritonitis.

Peritonitis by continuity is the uninterrupted extension of the inflammation from an infected area to the peritoneum and is accomplished by the invading army of micro-organisms through the lymphatics, blood-channels, or by direct penetration of tissues. The reactionary inflammation which determines the localization or diffusion depends upon the virulence of the bacteria, the resistance of the tissues, and, what is too frequently overlooked, the individual resistance of the patient. Puerperal peritonitis of streptococcus origin conspicuously illustrates inflammation by continuity.

Perforation peritonitis is the next subdivision of secondary peritonitis. The sudden opening of a focus of suppuration and the discharge of its contents into the peritoneal cavity, whether it be from hepatic abscess, a pus-tube or mesenteric

gland, is a true illustration of perforation peritonitis, yet the inflammation and systemic infection following is not necessarily so conspicuous. The duration of the primary disease, the virulence of the micro-organisms, the preparedness of the peritoneum by fortifications of adhesions, the general condition of the patient are all circumstances which may modify and circumscribe the peritonitis. It is more common for perforation peritonitis to occur as a result of ulceration of the wall of some of the hollow viscera as in peptic ulcer, typhoid and dysenteric intestinal ulceration, duodenal and appendicular ulceration.

The conclusions that may be drawn from an etiologic study of peritonitis may be thus summarized: Traumatic peritonitis, especially the post operative variety, is essentially a grave condition, not only because there is immediate or primary inoculation of the peritoneum, but the conditions are all favorable for germ culture and dissemination. Peritonitis by continuity may become general and prove rapidly fatal, but this is not the rule except in puerperal cases. Contrary to the expressed opinion of more than one writer, there is nothing peculiar about the peritoneum, or the cecum, or appendix, or the true pelvis, which accounts for the more frequent localization of inflammation in these regions than in other areas of the abdomen. The method of invasion, the activity of the process and resistance of patient alone determine the local or general type of peritonitis. Visceral perforation, whether traumatic or pathologic, is an ideal condition for germ culture and the elaboration of toxins. Their rapid absorption and general diffusion throughout the peritoneum sufficiently explain the grave state into which the patient is precipitated. It may be asserted that the clinical course and pathologic expression depend largely upon the nature of the exciting cause, the character of the pre existing disease or injury, and the mode of invasion.

Without attempting to formulate any definite pathologic classification of general peritonitis, and to adapt each to its special cause, he prefers to direct his efforts to simplifying and dispelling the confusion that exists. He accepts, with slight reservation, the now almost universally conceded idea that acute general peritonitis is and must be septic, that is, of bacterial origin. But he maintains that surgeons do not understand each other, nor have they all a clear conception of what is meant by septic peritonitis. It has been a race for life between the practical surgeon and bacteriologist as to who should claim the honor of naming the pathologic phenomena in this great serous bursa. He maintains that the surgeon is alone competent to define, classify and prognosticate the protean types of this disease. That men are honest, painstaking and accurate, goes without saying, yet how can surgeons reconcile the report of McCosh's last series of eight cases of general septic peritonitis and six operative recoveries with the experience of Senn "of many cases of diffuse septic peritonitis without a single successful result"? The answer certainly is not in the superior skill or special technique of the operator, but it is to be found in an analytic study of McCosh's cases, six of them were purulent peritonitis and two serous peritonitis, not the class of cases referred to by Senn at all. Tietze defines diffuse septic peritonitis to be "that form of peritonitis in which there is little or no exudate, severe symptoms of intoxication and terminating rapidly fatally." Some four years ago, Dr. Douglas reported eight cases of general peritonitis subjected to operation with four recoveries and four deaths. He dealt with them all as cases of general septic peritonitis from a misconception of the term. Two of them only properly belonged to this class and they terminated fatally. The others were cases of general purulent peritonitis with two deaths and four recoveries. He is very well pleased with his percentage of recoveries, but disgusted with his classification. He did not discriminate between diffuse septic peritonitis, the patient dying in twelve hours with profound toxemia and dry peritoneum after perforation of the appendix, and one of perforation with enormous purulent effusion, but mild symptoms of sepsis. This error of his is the common one with the profession, and it is the outcome of an attempt to classify peritonitis by the character of exudate.

The etiologic classification of peritonitis places it as subsidiary to the primary lesion which produces it and its practical import is its local origin. A painstaking investigation into the clinical history will usually determine the origin or structure primarily involved. The symptoms and physical signs, if the case is seen sufficiently early, will still further aid in incriminating the part under suspicion. This valuable diagnostic evidence does not conform to any stereotyped expression; the symptomatology of peritonitis is as varied as its causes. By the presence of any striking symptom or group of symptoms, physicians can not arrive at a decision in a doubtful case, but from the whole picture they must form conclusions.

(To be continued.)

Chicago Medical Society.

Regular Meeting, Nov. 30, 1898.

Dr. ARTHUR D. BEVAN officiated as chairman of the meeting.
Dr. F. KREISSL read a paper entitled

WHY IS GONORRHEA STILL A MUCH-DREADED DISEASE?

Speaking of the cause of failure in successfully dealing with gonorrhea, the author pointed out superficial diagnosis, incorrect conception of the gonorrheal process, improper selection of the remedies, and the almost universal tendency to begin with an effective treatment too late and to discontinue it too soon, and last, but not least, the lack of individualizing cases. He stated that hard and soft chancroidal ulcers, and the presence of mucous patches in the urethra during the secondary stage of syphilis, furnished a secretion which is mistaken for gonorrhea and is treated as such, until the appearance of local symptoms on the skin and other parts of the body direct attention to the real character of the discharge. The same applies to herpetic eruptions and tuberculosis of the urethra, leading to tubercular ulcerations, which may, in rare instances, be partially symptomatic of a more or less generalized urogenital tuberculosis or, in rarer cases, it may start primarily in the urethra. Simultaneous infection with gonorrhea and syphilis is not a very rare occurrence, and the same is true of a urethra affected with secondary syphilis, in which the gonococcus may become implanted.

The treatment of gonorrhea, in order to be effective, should be commenced as early as possible, to prevent the gonococcus from penetrating the tissues, and should be kept up until the physician is satisfied that all gonococci are annihilated. Silver salts still rank highest among the antigonorrheals, and their value in destroying the vitality of the gonococcus is being more and more appreciated. For the past fourteen months he has used protargol, a silver salt, which is highly recommended by Neisser, and which favorably compares with argonin in its prompt effect and total lack of irritation of the tissues. It has a strong penetrating power, and is therefore also applicable in the more chronic cases. But in treating a case with the silver salts the physician should not forget that more or less reaction follows each application, which manifests itself as a secretion lasting for from four hours to several days, according to the concentration of the solutions used.

A point of importance is that the silver salts in a certain concentration do not check the catarrh, and they ought, therefore, not to be expected to dry up the canal after having annihilated the gonococci. Astringents must be used to do this, which accomplish the desired result within a very short time. When this does not take place; when even a scanty secretion appears at the meatus, or filaments in the urine, the physician must look out for complications. The most common complications are strictures, or their forerunners—glandulitis or periglandulitis—or the disease may have invaded the posterior urethra, the seminal vesicles and Cowper's glands. By stripping the parts and making a microscopic examination of stained specimens, valuable information is gained as to the nature of the secretion, and any doubt is removed if the case is one of urethrorrhea, prostatorrhea or gonorrhea. The physician rarely has occasion to see posterior urethritis in those cases of acute gonorrhea which are treated with the silver salts from the start, provided the patient observes instructions in regard to diet and habits. As to the Valentine and Janet irrigations and the Oberlander-Kollman treatment with dilatation and flushing of the canal, either following each other or simultaneously, he remarked that reports as to their efficiency in cases of acute gonorrhea are contradictory. He would not recommend either. They might perhaps, by simply washing out, do good in a very mild case at a time when comparatively few gonococci appear on the surface of the urethra, but he believes they do much harm by causing traumatism in an acutely inflamed canal. In chronic cases, where the process is confined to a limited number of follicles, the combined treatment of cauterizing by the urethroscope or dilating and irrigating by experienced hands will be found gratifying. In closing, the author quoted a remark which is attributed to Ricord, namely, that "gonorrhea is a disease which starts as a slight burning on urination, but of which only the Lord knows when and how it will end."

Dr. THOS. J. WATKINS followed with a paper on "Gonorrhea in the Adult Female."

Dr. I. A. ABT contributed a paper on

GONORRHEA IN CHILDREN.

He said that gonorrheal infection of children manifests itself primarily as a vulvo-vaginitis, a urethritis of the male child, a purulent ophthalmia, stomatitis, or rhinitis of the new-born. He discussed genito-urinary gonorrhea and complications in

children. So frequently has the gonococcus been found in cases of vulvo-vaginitis, that no doubt can be felt that gonorrheal infection plays an important rôle in this disease. Cohen-Brach examined twenty-six children suffering from vulvo-vaginitis, and in every case but one gonococci were found. W. Fisher examined the secretion in fifty-four cases, in fifty of which he found gonococci. The disease occurs in children from one to 12 years of age, though it is most frequent in children under 6 years of age. As to the constitutional condition of the little girls, weakly or rachitic children are not particularly susceptible; on the contrary, the children as a rule are well developed and well nourished. As to the clinical course and symptomatology, on the inner surfaces of the thigh and on the perineum one usually observes an eczematous condition of the skin covered with a dried greenish-yellow pus. The labia majora adhere to one another. If they be separated, it is noticed that the mucous membrane of the vestibule is red and swollen, as is also the hymen, and a quantity of pus is to be seen; pressure upon the perineum will frequently cause pus to exude from the vagina. In the majority of cases the urethra is involved. It is not unusual to find the ducts of the Bartholinian glands involved, and a small quantity of pus can sometimes be pressed out of these ducts. Fisher reports a Bartholinian abscess. In many cases the inguinal glands are enlarged, particularly in those cases where eczema or excoriation exists. As a rule, the temperature is normal, though slight elevations during the first few days of the illness have been recorded. As a general thing, the subjective symptoms are trifling or absent. The intertrigo may cause itching, or there may be pain upon urination or vesical tenesmus. The disease may last for weeks or months. The urethritis may persist after the vulvo-vaginitis has terminated. Exacerbations and relapses are not uncommon. The endometrium is said never to be involved.

In children, as in the adult female, the tubes or ovaries and peritoneum may be involved. Gonorrheal pus in the tubes has been found at autopsy in five cases of girls from 7 to 9 years of age. The genitalia of little girls may be the point of entrance for the organisms which cause peritonitis. The bladder is seldom involved in little girls; a temporary vesical tenesmus, or in rare cases a temporary vesical catarrh, may occur.

Epidemics of vulvo-vaginitis have been frequently described; they occur particularly in hospitals and institutions, among the children of the poor, though none are exempt. Skutch describes what is probably the largest epidemic which has yet been reported in the city of Posen. During the month of August, 1890, 236 cases were reported, and probably many more occurred that never came to notice. These cases all developed in the course of eight to fourteen days in little girls from 6 to 14 years of age—school children. In a number of the children it was noticed that the disease occurred after they had visited on one or more occasions a free public bath. The common use of towels, soap, and the bath water may have carried the contagion from one child to the other. In the majority of cases gonococci were demonstrated. Purulent ophthalmia developed in a few, not a stated number of cases. The vulva and urethra are most often attacked primarily; the vagina, if involved, becomes so secondarily; the gonorrheal virus may be conveyed through sponges, towels, bed linen, by manipulations of the parts with unclean fingers, fever thermometers, or the contagion may, in rare cases, be conveyed by criminal assaults on little girls.

In a general way, it may be said that the prognosis in little girls is more favorable than in adults. In a majority of cases the disease terminates in three months, though there are cases recorded where a chronic urethritis resisted all forms of treatment.

The symptoms of gonorrheal urethritis in male children present much the same picture as is seen in the adult. Koplik has seen children in arms suffering from this condition. Bokai observed 109 cases of urethritis in children, many of whom, he points out, suffered for weeks or months from a urethritis. Most of these were probably gonorrheal. Twenty-seven occurred during the first year, 36 from the first to the third year, 32 from the third to the seventh year, and 14 from the seventh to the fourteenth year. Holmes has not infrequently seen cases of gonorrhea in male children. Rona says that in his fifteen cases the process was in every case a urethritis totalis, the disease becoming chronic, and usually lasting for months. Moncorvo has seen many cases of gonorrhea in small boys. Von Arsdale has frequently observed gonorrheal urethritis in young boys. One case was in a child ten months old; two cases were in children from one to four years. Dr. Abt has notes of two cases.

In private practice, as well as in hospital and dispensary practice, it is in most cases difficult to accurately elicit the mode of infection, though it can not be doubted that most

cases are due to actual sexual contact, a lesser number to manipulations of the parts with infected hands, linens, and the like. The recorded cases show that the majority of children acquire the disease from servants, or from little girls suffering from vulvo-vaginitis.

Strictures occur the same as in adults. Kammerer reports a case in a child two and a half years old, who, six months after an attack of gonorrhea, developed a stricture which did not permit the first catheter to pass. A suprapubic puncture was made to empty the bladder. Two strictures were found in the anterior urethra, and one impermeable in the membranous portion. The deep stricture was treated by performing an external urethrotomy. The anterior strictures were relieved by dilatation. Cystitis has been observed by Viger and Moncorvo. Rona encountered the complication in two cases. In one case it continued, and persistent hemorrhage occurred. It has been supposed that epididymitis and orchitis do not occur as complications, owing, perhaps, to the functional inactivity of the organs. True, the condition has been seldom observed, though Rona reports a child fifteen months old suffering from a urethritis totalis. In about twelve days after the beginning of the disease it was observed that the scrotum was swollen, and both testicles were painful. After fourteen months the patient was dismissed as cured, though a little hard nodule, the size of a pea, remained in the left epididymis. Lymphangitis of the penis, balanitis and balanoposthitis occur commonly. Rectal gonorrhea has not been observed in any of the cases previously reported.

The diagnosis presents but few difficulties, and differs in no important detail from that of adults. The specific must be differentiated from the non-specific variety. This differentiation depends on the presence or absence of the gonococci, and also upon the duration of the disease and the occurrence of complications. The gonococcus must be found in considerable number, and arranged in groups within the leucocytes. It must decolorize readily by Gram's method of staining. The best culture-medium is made from the blood or serum fluid of man. The treatment of vulvo-vaginitis, which the author considered at length, consists of cleanliness, antiseptics and rest of the parts.

Dr. D. N. EISENDRATH followed with a contribution on

PATHOLOGY OF GONORRHEA AND TREATMENT OF SOME SURGICAL COMPLICATIONS.

He said: The history of the gonococcus dates from 1879, when Neisser first found it in gonorrheal pus. It is a coccus occurring in pairs, generally in the interior of leucocytes, with a clear interspace between, with adjacent sides flattened (his cuit shaped). Its size varies from .8 to 1 in length and from .6 to .8 in width. In the tissues and pus its size is uniform; in cultures it varies. It is neither a strepto- nor a staphylococcus, but has a grouping of its own which is quite characteristic. It is non-motile and divides longitudinally. It is best stained with an alkaline methyl blue or gentian violet solution. It is decolorized by Gram's method. This serves to distinguish it from all other cocci except the so called pseudo-gonococci, and the meningococcus of Weicheelbaum. Lustgarten and Mannaberg described the former (pseudo-gonococci) as occurring in healthy and gonorrheal cases. It is a lemon-yellow diplococcus, decolorized by Gram's method and occurring in about 5 per cent. If all the well-known points, as to the morphology, staining reactions, enclosure and arrangement within cells be observed, a mistake in diagnosis is possible in only a small number of cases. The meningococcus, in its morphology, intracellular position, appearance in culture-media, decolorizing with the Gram stain, more completely resembles the gonococcus, but in this case as with the pseudo-gonococci, the culture-test is the only reliable one in doubtful cases, namely, the gonococcus will only grow on media in which some albumin taken from the human body is present and will not grow upon ordinary media; whereas the other cocci spoken of will grow well on all media. Bumm was the first to obtain successful results in the cultivation of the gonococcus by using human blood serum. On account of the difficulty of obtaining this serum Wertheim suggested a far more practicable medium in the shape of human blood-serum agar. Some human serum seems necessary, but ovarian, pleuritic, ascitic and hydrocele fluid can be substituted for the blood-serum. Many other media have been suggested, but none have proven satisfactory. If none of the above fluids can be obtained, a convenient method is that of Pfeiffer, namely, to allow a number of drops of blood from a previously sterilized finger to flow over the surface of a tube of nutrient agar. Surface colonies are pale, grayish, translucent, finely granular, with finely notched borders. The gonococcus is exclusively aerobic and is very sensitive to temperature.

One of the most interesting contributions to our knowledge of the gonococcus, since its discovery by Neisser and its cultivation by Bumm and Wertheim, has been made by de Christman, published last year in the *Annales de l'Institut Pasteur*. He isolated the toxin of the gonococcus from pure cultures growing in rabbit serum bouillon containing glucose, which he found better than the Wertheim medium. The injection of the toxin obtained from filtered cultures produces the same results as the cultures themselves. This toxin placed upon the human urethra, caused, after one hour had elapsed, a drop of thick yellow pus, which contained a large number of mono- and polynuclear leucocytes and epithelial cells, but no gonococci. The toxin acts first upon the epithelial cells, and the leucocytic emigration is secondary, because in the first drops taken the former greatly exceeded the latter in number. This artificial urethritis was accompanied by pain and the other typical symptoms, and disappeared gradually. It resembles the true gonorrhea in the fact that the secretion continues long after the inflammatory symptoms have disappeared. In cases in which there is a doubt as to the nature of the process, the injection of such a toxin would clear it up. In animals the injection of the toxin causes rapid loss of weight and high fever. Locally it causes abscesses, with thick sterile pus, no tendency to spread, and which heal by resorption. There are no lesions to be found postmortem. Heat has no effect upon the toxin; it can be precipitated by alcohol and extracted with glycerin. The toxin is formed in the bodies of the gonococci themselves. Injected into the anterior chamber of a rabbit's eye it produces great irritation and early pus formation. Injected into the pleural cavity, it produces rise of pulse and respiration and all the evidences of a pleuritis, with the formation of thick yellow pus. Animals can be immunized by intravenous injections of the toxin in thirty days, so that injections of pure cultures, or the toxin, have no effect. This may have a future in the treatment of some internal complications of gonorrhea.

In man the favorite ground for the gonococcus is upon mucous membranes, preferably those lined by cylindric or transitional epithelium, not excluding squamous, as Bumm claimed. It readily penetrates between the cells into the connective tissue and between muscle fibers. It grows most luxuriantly, however, upon the surface, and it is probably through the destructive action of its toxin, as de Christman has shown, upon epithelial cells and leucocytes, that pus is formed. The localization of the gonococcus in the joints and tendon sheaths may take place almost from the very beginning of the disease, and not necessarily from the time the posterior urethra is invaded, as was formerly thought, depending more upon the invasion of the deeper layers of the tissues of the urethra and bladder. They are greatly favored by trauma, excoriation, or irritating therapeutic measures. It is a frequent complication of the gonorrhea of pregnancy, or of the puerperium, of ophthalmia neonatorum, or of the vulvo-vaginitis of children. No joint can be said to be free from it. It does not generally involve, or wander from one joint to another, as acute articular rheumatism does, nor does it seem to be as polyarticular. In men the knees are most frequently affected, in women the wrists and finger-joints. The disease in the joints may be acute, sub-acute or chronic. Of the former there are three varieties: the acute gonorrheal hydrops, in which there is a serous or seropurulent effusion; a second variety in which, in addition to the effusion, there is extensive thickening of the capsule and involvement of the para-articular tissues. In this variety the exudate may at times be purulent, cause perforation of the capsule and peri-articular abscesses. A third variety resembles the ordinary pyemic arthritis, with destruction of cartilage and capsule. The second variety is the most deplorable, because in spite of all treatment it leads frequently to ankylosis. In general, the tendency of gonorrheal arthritis is through the early adhesions and capsular thickening, as well as particular infiltration, to lead to stiffness, subluxation and contractures. Examination of gonorrheal joints shows as the principal changes, loss of endothelium, and under this formation of granulation tissue, it is the change to connective tissue of the latter which leads to the above results.

Gonorrheal tendo-vaginitis and bursitis are not at all rare affections. The former occurs most frequently in the tendon sheaths of the extensors in the hand, and of the tibial muscles in the lower extremity; the latter in the bursa between the insertion of the tendo Achillis and the bone. The treatment of acute hydrops should be rest and compression with or without the application of some local remedy like guaiacol carbonate. The internal administration of salicylates, etc., is of but little avail. In the second variety, with extensive capsular and para-articular involvement, if a cast or a splint does not succeed within a short time, an early puncture of the joint with wash-

ing out with some antiseptic solution, e.g., bichlorid of mercury or lactate of silver with injection of iodoform emulsion, followed by massage, active and passive movements, will give the best results. If these latter means are not employed, fairly early, even in cases in which the joint is not washed out, ankylosis is almost certain to result. When the exudate is purulent, with high temperature and threatened destruction of the joint, arthrotomy is frequently necessary. The treatment of gonorrheal tendo-vaginitis is comparatively simple. It is rarely necessary to open the tendon sheaths in order to evacuate the pus, but even here the tendency to stiffness of the fingers and toes must not be forgotten, and early massage and movements should be insisted upon.

Dr. BERTRAM W. SIPPY contributed a paper on

GNORRHEA FROM THE STANDPOINT OF INTERNAL MEDICINE.

He said: The following etiologic factors are to be considered in the production of the metastatic inflammations of gonorrhea; 1, the presence in the part of the gonococcus; 2, the action of gonotoxins produced either at the site of the inflammation, or possibly conveyed by the blood to the part from the seat of primary infection; 3, secondary infection with various microorganisms; 4, mixed infection. Arthritis occurs as a metastatic complication of gonorrhea in from 2.5 to 3 per cent. of all cases. The clinical picture of the disease varies greatly. The most common form begins with pain in several joints. In a short time one or more of the painful articulations, the knee joint, usually, begins to swell rapidly. Pain may be intense or moderate. Soon fluctuation is present. During the first few days, a temperature of 102 of 103 degrees, and other constitutional symptoms attend the local process. In a few days, the acute symptoms subside, but the effusion remains. The subacute stage continues a few weeks, until the fluid is gradually absorbed. Real suppuration rarely takes place, and when it does, undoubtedly mixed infection with pus microbes is nearly always present.

In other cases, phlegmonous inflammation of the synovial membrane, ligaments, and peri-articular tissue may be accompanied by an exudate largely fibrinous in character. Stiffness of the joint is a marked feature from the beginning. Deformity may develop rapidly, and it is in this form that ankylosis is most likely to take place. Another form is characterized by peri-articular inflammation only. At times, the disease manifests itself as an acute polyarticular affection, resembling acute articular rheumatism. Chronic hydrops, involving usually one joint, may result from repeated exacerbations of the ordinary form of gonorrheal arthritis, or the process may be subacute or chronic from the beginning. Above all, that which characterizes gonorrheal arthritis is its appearance as a complication of gonorrhea, the fluctuation of the joint affection, with that of the primary gonorrheal disease, and the tendency to ankylosis. Endocarditis complicates gonorrheal processes much more rarely than arthritis. The left heart is more frequently affected. There is nothing characteristic in the symptomatology, aside from the etiology.

The prognosis is always doubtful. The most favorable cases are those in which the temperature is low or normal, and the physical signs of the disease not pronounced. Cases which were clinically ulcerative endocarditis, have recovered with chronic heart lesions.

Diseases of the brain, spinal cord, meninges, cranial and peripheral nerves have been reported on good authority, in which gonorrhea was regarded as the etiologic factor. Anatomic disease, however, is rare. Relatively, the peripheral nerves are most frequently affected. The condition is either a neuralgia or neuritis. Thirty-five or forty cases of spinal cord lesions, including several autopsies, have been reported. A myelomeningitis, involving the lumbar cord, is the most common lesion. The disease may be acute, but is usually chronic. Functional disease of the nervous system is much more common. The neuroses may be general or local. There is nothing specific in the symptomatology of nervous disease complicating gonorrhea. A relatively large number of cases of myelomeningitis have recovered. Bacteriologic research has been attempted a few times. Thus far the gonococcus has not been found.

Chicago Gynecological Society.

Regular Meeting, Nov. 19, 1898.

Dr. NICHOLAS SENN, the president of the society, occupied the chair.

The society discussed the subject of

CYSTITIS IN THE FEMALE.

Dr. SENN opened the discussion by dealing with the etiology and classification. He said that the recent great advancements

in the prevention and more successful treatment of infective surgical diseases are the direct outcome of the vast increase of our knowledge concerning their etiology. Surgical bacteriology paved the way for rational surgery. It is now very generally conceded that inflammation of any tissue or organ is invariably caused by microbic invasion, and that all other causes only act by determining or favoring infection. If this be true, it is apparent that the successful treatment of cystitis presupposes an accurate knowledge of the nature of the microbic origin of the inflammation. Suppurative cystitis and tubercular cystitis are so entirely different in the nature of their bacteriologic origin that the method of treatment successful in one would almost with certainty aggravate the other. Inflammation of the bladder is often the result of a mixed infection, and it is of paramount importance in all such cases to gain accurate information by bacteriologic examination of the urine concerning the part which each kind of microbe plays in the causation and continuance of the inflammatory lesion before an intelligent and successful course of treatment can be devised and carried into effect. It is of special importance in the successful management of cystitis and conditions mimicking cystitis clinically to make a sharp distinction between the cases in which the symptoms are caused by inflammation and those in which they are due to non-inflammatory pathologic conditions. It will be seen from what has been said that the modern etiologic study of cystitis is based largely on a carefully conducted bacteriologic examination of the urine. The exercise of patience and perseverance is often required, as in many cases the urine has to be examined repeatedly before the necessary information is gained.

Predisposing causes do one of two things or both: 1. They effect tissue changes which determine the localization of microbes from the bladder, adjacent organs or the general circulation. 2. They furnish a nutrient medium for the growth and multiplication of microbes. The most frequent of all predisposing causes of cystitis is retention of urine from any cause. Abnormally increased muscular action of the bladder as occurs in cases of central or peripheral irritation of the nerves which preside over the muscular structure of this organ, or in consequence of the action of local irritants, as acetone, foreign bodies, tumors, chemic or toxic substances, is a recognized predisposing cause of inflammation of the bladder. Abnormal conditions affecting the quality or quantity of urine frequently precede inflammation of the bladder, and must be regarded in the light of predisposing causes. Tumors of the bladder, malignant and benign, frequently precede and complicate cystitis. A calculus or a foreign body becomes a predisposing cause of cystitis by the production of local lesions and vascular changes favorable to the localization and growth of bacteria, which are the essential cause of the inflammation. Compression of the bladder from within and from without is a potent predisposing cause of cystitis. Pressure from either direction diminishes the vascularity and nutrition of the bladder wall, and in this way increases the susceptibility of the tissues to invasion by disease-producing microorganisms. Venous stasis is a local predisposing cause of cystitis. To trauma has been assigned for centuries a direct influence in the causation of cystitis.

The essential or exciting cause of cystitis is invariably the presence and pathogenic action of microbes in the tissues of the bladder, the seat of inflammation. In the study of etiology of cystitis it is important to consider in detail the routes of infection. Under the head of exciting causes, Dr. Senn dealt with infection through the urethra, infection by the urine, infection from adjacent organs and infection from the blood.

Coming to the classification of cystitis, he said that a rational classification is essential in discussing the etiology, symptomatology, diagnosis, prognosis and treatment of this disease. He gave both Guyon's and Rovsing's classifications of cystitis. In the anatomic classification, pericystitis, paracystitis, interstitial cystitis and endocystitis were enumerated and dwelt upon at length. Under the head of pathologic classification he gave catarrhal cystitis; suppurative cystitis; ulcerative cystitis; exudative cystitis; exfoliative cystitis and dwelt upon each of these forms at considerable length. In the clinical classification he gave acute cystitis, and chronic cystitis, and in the bacteriologic classification: 1, bacillus coli commune infection; 2, saprophytic (mixed) infection; 3, staphylococcus infection; 4, streptococcus infection; 5, streptococcus erysipellatus infection; 6, typhoid bacillus infection; 7, diplo-bacillus infection; 8, Gonococcus infection, and 9, bacillus of tuberculosis infection. The bacteriologic classification of cystitis is the most modern and certainly the most important. It has a direct bearing on the etiology of the disease, and suggests to the surgeon the most rational course to pursue in its treatment. In long-standing and obscure cases of inflammation of the bladder, examination is not complete without examination of the urine

with sufficient care and thoroughness upon which to base a correct bacteriologic classification. Surgeons must learn to appreciate the value and importance of this part of the examination before they can expect material advances in the treatment of cystitis. If the surgeon has not the necessary knowledge or equipment to make these examinations satisfactorily, he should assign this part of his task to a competent bacteriologist.

Dr. JOHN A. WESENER followed with a paper on the
CHEMIC AND MICROSCOPIC EXAMINATION OF THE URINE, WITH
SPECIAL REFERENCE TO THE DIAGNOSIS OF CYSTITIS.

He said that very little had been done on the microscopic and chemic examination of the urine in cases of cystitis. It is true, we are told to differentiate cystitis from pyelitis by the character of the epithelium present. In the case of females, in whom cystitis is suspected, the urine should be obtained by the catheter. If this rule be followed, it will avoid the possibilities of contamination from the vagina. Cystitic urine may be either acid or alkaline. If the infection is by the bacillus coli, it is acid; if in addition it becomes infected with the bacillus vulgaris, it becomes alkaline. Of 200 cystitic urines examined, 68 per cent. were acid and 21 per cent. alkaline. Of the alkaline urines found, decomposition took place in some after voiding. The reaction of the urine no doubt depends on the character of the bacteria present. The works of Rotoski, Krogin and Müller justify the above assertion. Müller found cystitic urine acid in 75 per cent. of all cases examined by him; while Melchoir showed from an analysis of sixty-two cases, that ammoniac decomposition is only a subordinate circumstance in cystitis, depending solely on the microbe present. The most important of these is proteus vulgaris.

To differentiate cystitis from pyelitis, Dr. Wesener proceeds as follows: In cystitis there is always more pus than in pyelitis, and for this reason kidney epithelium is found more readily in pyelitis because of the smaller amount of pus present. After centrifuging the urine, it should be tested for the amount of albumin it contains. In cystitis it is found absent or present, depending on the amount of pus; whereas, in pyelitis, a considerable quantity of albumin is always found. The explanation for this difference is due to the fact that the kidney is a much more vascular organ than the bladder; therefore, exudation takes place more easily. Red-blood cells are found more frequently in pyelitis than in cystitis. In pyelitis casts are often found. Clinically, we might succeed in distinguishing these two conditions by washing out the bladder with sterilized water immediately after urination; examine the urine collected, and also the washings for pus. If the water contains a considerable amount of pus, it is probably cystitis.

Dr. WILLIAM T. BELFIELD then discussed

INSTRUMENTAL EXAMINATION OF THE BLADDER IN CASES OF CYSTITIS.

He said that twenty years ago cystitis was a clinical entity characterized by the presence of three symptoms—retention, frequent and painful urination, and pus in the urine. To day it clinically had receded from the rank of an entity to that of a symptom. The symptoms considered characteristic of inflammation of the bladder today, such as frequent and painful urination and pus in the urine, are now known to be caused, not merely by inflammation of the bladder as a whole, but also by infections, injuries to certain limited parts of the bladder, etc. Now, other parts of the urinary organs are involved, such as stricture of the urethra, and morbid conditions of the pelvis or the kidney. The reason why the cystitis has thus receded from the first and second ranks from that of an entity to that of a symptom has been especially set forth by Dr. Senn, viz., that cystitis is always to be considered in the nature of a bacterial infection, and that the bladder is not susceptible to bacterial infection when it is in a normal condition. The reason why so much advance has been made in the matter of cystitis is because of the improvement in means for the mechanical examination of the bladder. Twenty years ago the sound was the only instrument in use. It revealed the existence of stricture, of foreign bodies in the bladder encrusted with urinary salts, and with the aid of the finger, prostatic hypertrophy in the male. It is true, the finger was sometimes used for the investigation of the female bladder, but it was not generally recognized nor a universally employed measure. Dr. Belfield then referred to the value of the cystoscope as affording means for inspecting the entire wall of the bladder. There are instances on record in which stones have been entirely cut off from the general bladder cavity under diverticula, but they are rare. There are plenty of others which present a free surface to the bladder cavity, but in such localities as to be entirely beyond the reach of the sound. He related a case in which the ordinary symptoms of chronic cystitis were present,

and likewise symptoms strongly indicative of stone in the bladder. The man had had the matter of castration strongly urged upon him, but fortunately refused. An examination without an anesthetic failed to discover stone; the cystoscope at once revealed a stone near the protruding part of the prostate, just above the urethral orifice. A couple of weeks later the man was operated upon. When the patient was chloroformed, sounds were introduced with curvature likely to lead to the locality where the stone was known to be located. Dr. Belfield was unable, however, to touch the stone. A suprapubic incision was therefore made and the stone removed. Cases of this kind show the extreme value of the cystoscope.

Dr. M. L. HARRIS followed with a brief paper entitled

INSTRUMENTAL EXAMINATION OF THE BLADDER IN THE DIAG- NOSIS OF CYSTITIS IN THE FEMALE.

His remarks were confined entirely to instrumentation of the bladder as bearing upon diagnosis, and were still further limited to a consideration of his own instrument—the urine segregator—which possesses the following advantages:

1. It collects the urine, so that it may be analyzed.
2. It does this without entering the ureters, thus obviating the danger of infecting the kidneys.
3. It not only enables the physician to differentiate bladder from kidney disease, but to determine the exact condition of each kidney, which is so essential in all diseases of the urinary tract.
4. Its use is so simple that extraordinary skill is not required.

Dr. JAMES H. ETHERIDGE read a paper entitled

REMEDIAL TREATMENT OF CYSTITIS IN THE FEMALE.

He said that the treatment of cystitis is conveniently subdivided into constitutional and local. The constitutional treatment consists chiefly of the use of remedies to increase the functions of the alimentary canal, of the skin, of the use of agents whose action so changes the character of the urine that it shall be unirritating to the diseased organs, and of medicines that can relieve pain and vesical tenesmus. Diet also falls under this heading. A soluble condition of the bowels should be maintained daily by salines, taken on the empty stomach, before breakfast. It is of prime importance to bear in mind that a glass of hot water taken immediately after the saline will energize the latter wonderfully, so that a diminished quantity of the drug will suffice. For example, a glass of hot water will make one-half or even one third of the dose of Hunyadi water that will move the bowels, effective and satisfactory. It is a matter of therapeutic experience that three daily bowel movements contribute to relieve the sufferings of an inflamed bladder. Diversion of the blood-current toward the intestinal canal under saline laxatives tends to diminish the amount of blood in the walls of the bladder. He recalled two cases of hypercatharsis in women with cystitis, one from physic and the other from a poisoned food product, wherein recovery in one and great temporary relief in the other case followed. The diet of cystitis patients should be carefully regulated. Milk is the most universally used agent. For the relief of pain and tenesmus, analgesics are demanded. Opium is the supreme agent for the relief of vesical suffering. It can be used as Dover's powder, with camphor, also in rectal suppositories. It has its drawback, most decidedly, in the way of deranging the secretions and excretions. Its chief objection is the induction of the opium habit. Other agents, as chloral hydrate and the bromids, very often bring relief from pain. They are without the objections of the opium. The indications for the medical treatment lie chiefly in the reaction of the urine. If the urine is too acid, or very acid, it should be alkalized. If it be alkaline, remedies must be given to change such reaction. Remedies can be given by the stomach to accomplish these ends. The treatment of all cases of cystitis involves two classes of remedies—those for use by way of the stomach, and those for use in the bladder. The second subdivision of the remedies used internally in cystitis is the class called germicidal agents. Their name is legion. Many of them have been used for generations. The older germicidal remedies include creosote, used especially where tubercle bacilli are found, cubebs, copaiba, oil of sandalwood, tar water, uva ursi, buchu, sodium salicylate, pareira brava, and the sulphocarbolates. Under this division come the balsams and the terebinthines. These remedies are all old, but they are reliable.

The essayist next dwelt on the important remedies for local use in the bladder. Before using medicines in the bladder, this viscus must be washed out with a normal sterilized salt solution, a dram to the quart, or with a saturated solution of boric acid. He uses the latter wholly. The injection must be small in amount, usually an ounce or two in severe cases, and given slowly. The selection of the remedy for intravesical application depends somewhat upon what the urinalysis reveals.

In all cases of simple cystitis the sovereign remedy is silver nitrate .1 to .5 per cent. In obstinate cases, this is one of the most reliable agents in strong solution, say twenty grains to the ounce. Of this five or ten drops only are used. The smallest amount should be used at first, larger ones later. Its use is not very painful; only exceptionally is it so. One to three or four drams can be used. At first it can be used once in two days; later, daily, till its further use can be discontinued. Simultaneously with its use, needed remedies by the stomach must be given for acting on the urine. The local treatment of the bladder should be performed with complete antiseptic precautions. The first thing done should be to wash out the bladder as completely as possible with saline solution or with a saturated solution of boric acid. In the majority of cases of cystitis this line of daily treatment is sufficient. When no improvement occurs in ten or fourteen days, the mild solution of the silver nitrate can be used with every expectation of a successful issue. Many physicians use this agent to begin with, claiming that since silver nitrate is the chief of all remedies for inflammation of mucous membranes and that days of time are gained by commencing all treatment of cystitis by using it. Such a claim sounds well, and it seldom disappoints the physician. Cases that resist all local and general treatment combined fall under the surgeon's hands.

Dr. ALEXANDER HUGH FERGUSON made some remarks on

THE SURGICAL TREATMENT OF CYSTITIS IN THE FEMALE.

He thinks chronic cystitis demands surgical treatment. In cases of cystitis in the female, local applications can be made through the cystoscope, and curettage could be performed. The application of nitrate of silver, and various topical applications, can be made to inflamed areas and ulcers of the bladder. Suprapubic cystotomy in the female has been done and there may be some cases calling for its performance, still he believes there is very little benefit to be derived from drainage suprapubically. Colpocystotomy, as practiced in cases of cystitis in the female, needs only to be mentioned to be condemned. Draining the bladder through the vagina, causing great discomfort and discharge of urine through that avenue, necessitates subsequent operation to cure the vesicovaginal fistula. He only did this operation once, and he always regretted it because he had to do three subsequent operations before the vesicovaginal fistula was closed. A careful examination should be made of the uterus and tubes. Examination of the kidneys should receive attention before the bladder is treated, sometimes after. If there is a tubercular condition of the kidney, it had better be treated surgically before the secondary vesical condition, because extension of the disease to the kidney is much more dangerous than extension of the tubercular disease of that organ to the bladder, which can be treated secondarily.

Dr. G. A. KLETSCH of Milwaukee, in the general discussion which followed the presentation of the above symposium, by invitation, read a short paper on

THE PREVENTION OF CYSTITIS IN THE FEMALE.

He said: An irritated condition of the bladder producing a congestion is frequently present in the female; but as soon as the cause of the irritation is removed, the bladder symptoms disappear. This was best illustrated to him in his hospital days by a demonstration of Dr. Emmet's. In a posterior parametritis, he would fix the cause of an irritable bladder, which would have eventually ended in a cystitis, in inflammation of the uterosacral ligaments. He contended that the inflammation in them soon led to contraction and shortening, and consequent dragging of the uterus into the hollow of the sacrum. This made tension on the neck of the bladder at its fixed point under the symphysis pubis, the base being attached to the cervix. He buttonholed the urethra to relieve this strain, thereby allaying the frequent desire to urinate, and then treated the seat of the disturbance to overcome the cause of the trouble. This teaches two things in the prevention of bladder troubles: 1, to avoid introducing a cause from which a cystitis might arise; 2, to relieve the patient of the one present without the introduction of another through any action of the physician. One condition alone can long exist without ending in a cystitis. In the autopsy room he has examined many a case, in which a hyperemic condition of the mucous membrane of the bladder was found, this not having developed further than an increase of the vascularity of the part. Frequently the intense vascularity indicated that it must have been of long standing, and still no inflammatory process resulted. The one element alone was present, which in itself was not sufficient to bring about a cystitis.

It is a question in his mind whether infection alone can produce a cystitis. Experimentation on animals has been carried on to decide this point. When the infectious material was carried into the bladder, was there not a lesion produced which

was the seat of inoculation? When called upon to enter the bladder, the one element was present, usually a congestion, and the physician introduces the other from without through the passing of the catheter. This behooves physicians to practice great care when they are called upon to exercise this function. Not only must all infection be removed from the parts under observation, but the instrument used must be thoroughly sterilized. Care must also be observed not to lacerate the tissues; for if the bladder contains decomposed urine, as it usually does, infection would find a fresh nidus by which it could enter and bring about its work of destruction.

Further discussion of the papers was participated in by Drs. F. Kreissl, E. C. Dudley, Albert Goldspohn, William Cuthbertson, Charles S. Bacon, L. L. McArthur and Lester E. Frankenthal.

French Congress of Surgery.

Held at Paris, October 18 to 22, 1898.

GUYON delivered an able and interesting address on

NEPHROTOMY

which, he observed, should aim to destroy the smallest possible amount of the renal parenchyma, bleed as little as possible and expose the maximum of renal tissue. This is best accomplished with a lumbar recto-curved or oblique incision. After having freed the organ from its adipose envelope, it is drawn out as much as possible and the pedicle compressed by an assistant. The organ is then opened with a long incision on its convex edge extending into the pelvis. By introducing a finger into the organ and palpating from the outside with the other hand, a calculus could scarcely be overlooked, although lesions of miliary tuberculosis might escape observation in the cortic substance, and even a neoplasm, as in an instance related, in which the lesions seem insignificant, until the microscope revealed the structure of alveolar cancer in a small fragment of false membrane discovered, and nephrectomy confirmed the existence of a renal neoplasm which had escaped attention. He considers nephrotomy superior to pyelotomy for the removal of calculi, except in the one case when palpation demonstrates a regularly shaped, medium-sized calculus in the pelvis. The best incision for nephrostomy is the lumbar recto-curved or oblique, downward and outward. This incision at once reaches Henle's vertebro-costal ligament, useful in managing the pleura. After having incised the convex edge of the organ and explored the inside, the walls between the different divisions should be destroyed as much as possible, and to avoid purulent peripheral lesions and facilitate future operations, the two valves of the renal tissue should be sutured to the lips of the parietal wound, as close to the integument as possible, thus evacuating and re-establishing the function of the kidney in case of anuria. He called attention to the remarkable tolerance of the kidney for this operation, with or without previous retention. Notwithstanding the free communication of the organ with the exterior and the drainage, infection does not invade the tissues. There is merely a slight sclerosis extending inward more or less from the edges of the wound. The renal tissue is not affected and the urine of a nephrotomized kidney scarcely differs from normal. Nephrotomy seems the superior operation in most cases of calculous anuria, and the only operation in serious cases. Both kidneys are usually more or less affected even in simple primary lithiasis, and in most cases the other kidney is no longer working properly when the anuria appears. It may seem normal in some cases, but is still liable to have lesions of an aseptic nephritis when render it particularly sensitive to the inhibiting influence of a reflex emanating from the other kidney (Guyon's reno-renal reflex). Nephrotomy is far from the ideal conservative operation in uronephrosis. The cause should be removed if possible, with ureteral catheterism, nephrorrhaphy, ureterotomy or ureteropyelotomy. But if the other kidney is destroyed and it is indispensable to retain all of the renal parenchyma that has been spared, then nephrotomy is directly indicated. The advantages of nephrotomy in simple pyonephrosis are evident. The objection of the fistula has been shown to be unfounded, as in many cases it heals in a few months or even several years after the intervention, and the more readily, the greater the destruction of the kidney. In certain cases the fistula can be prevented or healed by simple permanent ureteral catheterism, or by operations re-establishing the normal course of the urine. Secondary nephrectomy always offers a last resource when healing is evidently impossible and the secretion of the kidney has no longer any actual physiologic value. Nephrotomy is almost always preferable to interventions aiming to re-establish the normal course of the urine. These should be made later, after the

nephrostomy, when the general and local conditions are improved. Guyon's experience with nephrostomy in tuberculous pyonephrosis has been unfavorable. The improvement is always transient. The fistula has always persisted and no patient survived over two years. He prefers nephrectomy in these cases, if the other kidney is normal. The mortality of primary nephrectomy as published is 28 per cent. and of secondary nephrectomy 34 per cent. His experience has been sixteen recoveries out of seventeen primary nephrectomies for renal tuberculosis. Summarizing his cases with those of Czerny, Bardenheuer, Küster, Israel, Tuffier and Routier, he has a mortality of 10 per cent. while the mortality was 17 per cent. in 84 nephrostomies for renal tuberculosis. The latter operation is therefore only indicated when there are other advanced tuberculous lesions which would render nephrectomy impossible. In such cases it is well to take advantage of the undoubted palliative relief of the permanent opening of the kidney, although, after several weeks or months, the phenomena return as before. Radiography has not fulfilled the hopes of its application to the kidneys.

LE DENTU recommended multiple punctures all through the organ, and nephrotomy, in case of nephritis with much pain, persisting months and years in spite of medical treatment.

REYNIER's experience has been the necessity of a secondary nephrectomy in every case nephrotomized, and he considers primary nephrectomy no more serious than secondary.

BAZY rejects as useless or impossible the fastening of the renal edges to the skin. He makes his incision from the costomuscular angle to a point two or three finger breadths above the highest part of the iliac crest. After nephrectomy he places a bougie in the ureter through the pelvis, to ensure the permeability of the tunnel and prevent its obstruction by clots or pus after the operation. He recommends cystoscopy and the use of methylene blue as the best means of exploring the condition of the other kidney, observing that catheterism of the ureter may carry the infection into a sound ureter from an infected bladder. He reports only two cases in fifty nephrotomies, in which he had to operate twice, and only three in which a secondary nephrectomy was necessary. Tuffier reported fifty-seven nephrotomies: in three cases through an abdominal incision, with the precaution to suture the prerenal peritoneum to the parietal peritoneum before opening the purulent pocket of the pyonephrosis. He noted in many cases the existence of very small, almost microscopic foci at the nephrotomy, which developed later into multiple abscesses. He considers nephrectomy indicated not only for lithiasis and pain as suggested by Le Dentu, but also for renal hemorrhage and certain forms of nephritis. It should be performed as early as possible. He rejects nephrotomy in cases of hydronephrosis, preferring plastic operations to re-establish the course of the urine.

DOYEN reported a patient cured and in perfect health eleven years after nephrotomy, preceded by an incision of the kidney which showed it invaded by miliary tuberculosis. He avoids the dangers of retrograde catheterism by first carefully rinsing out the bladder and then having each ureter compressed in turn. Pus is then found in the urine after compression of the ureter on the side of the suppuration, but if the other kidney is sound no pus is found after the bladder has been rinsed again and the other ureter compressed.

LEGUEU described a case in which nothing was found at the nephrotomy, and yet the patient was very much benefited by the purely exploratory operation. The trouble had evidently been renal neuralgia in a very nervous woman.

ALBARRAN observed that a fistula is rare in a kidney not distended at the moment of operating, outside of tuberculosis. But when there is retention a fistula is frequent, on account of the constriction, the bending, or the vicious insertion of the ureter in the pyelorenal pocket. When the course of the urine through the ureter is once established, the fistula closes spontaneously; this he accomplishes by inserting a permanent sound. In case of a fistulous opening, if the analysis of the urine indicates benefit from retaining the organ, he inserts a sound, replacing it by larger sizes during the days following, using it for irrigations of the kidney pocket and withdrawing it in a fortnight. If in spite of the closing of the fistula, there are still indications of retention, he inserts the sound as far as it will go, and then incises the kidney, finding the ureter by means of the sound, and performing ureterotomy, ureteropyelostomy, uretero-pyeloneostomy, autoplasmic resection of the kidney or "capitonnage" of the pyelorenal pocket. With a purulent fistula a careful diagnosis should be made with ureteral catheterism. If the kidney secretes pus through the sound, cleanse and open wide the perirenal foci. The kidney should not be extirpated unless it is impossible to empty these foci without ablation of the organ. If the kidney is not secreting at all, nephrectomy is indicated. In regard to operations

to re-establish the normal course of the urine, he advises not operating at the same time as the nephrostomy, but waiting for the inflammation to subside. He also recommends not hurrying the healing of the fistula. After a while the ureteritis may subside and the conditions become more favorable.

PHOCAS reported a case of six months' insanity consecutive to a nephrotomy.

DELBET described the remarkable result of nephrotomy in a man of 60 years, too weak from his tuberculous pyonephrosis to undergo nephrectomy. Five liters of pus and 360 c.c. of cheesy substance were removed. He curetted every three or four days, and injected iodoformed ether every second day. The patient was dying at the moment of the intervention, but recovered, has gained in weight and seems quite well a year later, still keeping his fistula.

LOUVEAU related a case of severe renal hematuria nephrotomized and cured, although no appreciable lesions were discovered.

JONNESCO also emphasized the absolute benignity and unquestionable efficacy of nephrotomy and nephrolithotomy, followed by the immediate suture of the kidney.

CHIBRET reported the unique case of a vigorous man of 55 years, in good health except an attack of nephritic colic and complete anuria. A nephrotomy failed to show any calculi or gravel, but the kidney was nearly twice its normal size, purple, very much congested and so friable that when he tried to draw it out to the wound, his fingers sank into it as into a soft substance, and it was with the finger that he opened it down to the pelvis; smooth recovery.

REVERDIN of Geneva, in his address on

THE SURGICAL TREATMENT OF GOITER,

stated that the mortality in 6103 operations has been 2.88 per cent., but eliminating the older, complicated cases, the mortality would be very little above zero. The mortality from total extirpation has been 26 deaths in 137 operations; from interglandular enucleation, less than 0.78 per cent.; from the combined methods, 2.99 per cent.; from Mikulicz' resection, 6.66 per cent., and from partial extirpation, 3.56 per cent. Several enlarged upon the dangers of chloroform and expressed their preference for cocaine in their operation.

DOYEN inserts a tube in the larynx, by which means he can use chloroform at will. He stated that with his "crushers" he can perform thyroidectomy in five to ten minutes.

ROUX mentioned that he had long ago discarded chloroform anesthesia, but that he found pulmonary disorders afterward, usually attributed to the chloroform were as frequent as without it. Hundreds of enucleations were reported by other members with only one death (paralysis of the heart).

GIRARD operated on one woman in labor on account of imminent suffocation. The child was born dead but the mother recovered.

BERARD mentioned that after partial operations on the thyroid, fever and nervous phenomena are frequently observed, not serious, evidently due to the liberation of substances normally secreted by the gland which produced the "thyroid fever."

PICQUÉ classified "Otitic Suppurations" as osteodural, intradural, pericerebellar and intracerebellar abscesses, the latter either cortical or medullary and requiring more than simple trephining—an osteoplastic operation with a mastoido-occipital flap, retro- and sub-sinuous, which allows full inspection of the cerebellar pocket.

LANDOLT extolled the advantages of his method of treating strabismus—detaching the muscle and attaching it with a couple of stitches near the cornea. In case of extreme strabismus he combines with the advancement, the resection of the tendon end of the muscle, and supplements the operation with orthoptic exercises.

FAURE suggested treating facial paralysis by an anastomosis between the peripheral end of the facial nerve and the end of the spinal nerve—the trapezian branch severed at a convenient point.

COUDRAY recommended resection of the external branch of the spinal as the best treatment for spasmodic torticollis.

CALOT reported many cures of affections of the cervical glands without scars by injecting two or three grams of a fiftieth solution of chlorid of zinc with a very fine needle three or four times, with an interval of two days, completing the cure with injections of camphorated naphthol.

JONNESCO reported six recoveries in sixteen operations of temporary craniectomy (fourteen hemicraniotomies, two partial craniectomies; in four cases resection of the cortex to a greater or less extent. In eleven cases the operation was performed to relieve edema of the brain. One patient died from hemorrhage; two from later development. The six recoveries included two

of traumatic and one of Jacksonian epilepsy, two hysteria with prostration and idiotism, with mania. There were two much affected; six were unaffected by the operation (two epileptics with acute mania and four idiots).

LEGUEU described a case of extirpation of a mammary neoplasm, in which an early recurrence required operating, leaving a large defect. As all the available flaps had been used in the first operation he detached the sound breast and sutured it with the nipple on the median line, as a large flap, with success.

FROELICH reported twelve recoveries in twenty-six cases of Potts' disease in infants, which he treated by strapping the child, dressed, to a board in extreme lordosis. Four died and ten are still under treatment. He noted that the paralysis is localized in the two members, but is never absolute.

TUFFIER announced that his attempts to cause atrophy in inoperable tumors with "atrophy ligatures," had failed to produce the slightest curative effect, although as a palliative measure they procure the cessation of the ichorous and other discharges.

LARGER stated that he had found local or general baths of saturated solution of potassium chlorate extremely effective in relieving the pain in extensive burns. He continues the application of the chlorate in compresses on a superficial burn, and treats a deep burn as an ordinary after the pain has been relieved. The fact was emphasized by several, that patients apply earlier for an operation now than formerly.

ROUX observed in the conclusion to his review of two years of gastro-intestinal surgery, that the Y-posterior-gastro-enterostomy, with a suture in three stages, is not in itself a dangerous operation, notwithstanding its length and the possible escape of a little of the intestinal contents; as in twenty-four gastro-enterostomies for pylorus affections he has not lost a single patient. The operation was completed in forty-three minutes. Almost all were cicatricial constrictions or fibrinous rings from old gastrophtoses.

TUFFIER observed that he did not decide upon the method of "abouchment until after he had removed the tumors and considered the conditions left. His record is, sixty-two operations on the stomach; fifty gastro-enterostomies, with two deaths; nine pylorotomies (three deaths and six cures) and three operations limited to detaching adhesences.

DOYEN advocates the Y-anastomosis, like Roux, but makes the abouchement lateral instead of terminal, which reduces to the minimum the orifice for the passage of the bile into the jejunum, thus avoiding the regurgitation of bile. The gastro-enterostomy should be as far as possible on the face of the stomach and transmeso-colic. This insures the slope and emptying of the stomach contents.

DOYEN was the first to propose surgical intervention for non-cancerous affections of the stomach, not only for ulcer and cicatricial stenosis, but for spasmodic contraction of the pylorus with enlarged or contracted stomach. His method of pylorotomy consists in isolating the tumor, holding the gastro-colic omentum out of the way with a few ligatures, then applying his "crushers" beyond the tumor on the duodenum, reducing the intestine to the single thickness of the serous coat. A double ligature is placed in the groove and the intestine cut between the two ligatures, thus avoiding the escape of any fluid. The resulting stump is pushed back into the duodenal cavity with a double "purse" suture, after having removed, with scissors and thermocautery, any scraps of mucosa beyond the thread. The same operation is then done on the side toward the stomach, which can be pivoted outward. The forceps must be applied twice and a strong thread tied firmly in the groove. If the tumor is small a double purse suture is enough, but if large, a couple of superposed rows of overcast sutures are required. He proceeds to the gastro-enterostomy by perforating the mesocolon, and drawing down the posterior face of the stomach. The edge of the orifice of the mesocolon is overcast to the stomach, preventing the strangling of the small intestine at this point. The loop of the jejunum is drawn up, fastened to the stomach, and a lateral anastomosis made, after which the origin of the jejunum is sectioned with the "crushers" between a double ligature. The two stumps are finished as before with the purse suture. At this moment the stomach communicates with the jejunum laterally anastomosed, the upper end of which forms a cul-de-sac. The duodenum and the origin of the jejunum have become a tube closed at both ends. Nothing further is required except a lateral jejuno-jejunal anastomosis with a very small opening for the bile. The duodenum by this process becomes a prolongation of the common bile and the pancreatic ducts. This method of operating: "crushing," the purse ligature, and Doyen's elastic jaw forceps, realizes the most aseptic conditions, allowing gastro and enterostomosis without any

contamination of the field by fluids from the alimentary canal. He applies the same method to all his operations on the stomach, small or large intestine and especially to the resection of the appendix (*vide JOURNAL*, page 73).

LUCAS-CHAMPIONNIÈRE confirmed the great advantages of his method of mobilizing fractures from the first (*vide JOURNAL*, xxviii, page 1034).

MASSE reported that a number of dogs that had cholecysto-gastrostomy performed on them over a year ago, are still well, with normal digestion in spite of the presence of bile in the stomach. The common bile-duct had been ligated in the middle in most of them. The results indicate that this operation could be applied successfully to man in case of total obstruction of the bile-duct. The tolerance of the stomach for the bile also indicates that the care taken to prevent possible reflux of the bile into the stomach in gastro-enterostomies has been unnecessary.

GUINARD mentioned, as an aid in the diagnosis of perforating gastric ulcers, the appearance of the pain as a sudden sharp stab, near the left false ribs on the nipple line; the peculiar form of the tympanism and the ballooning of the abdomen and, especially, the record of the gastric past. Only two successes were noted in the eleven cases operated reported by several present.

WALTHER has observed the pain in two cases occurring in the lower abdomen, where there was an encysted peritonitis, connected with the perforation by adhesences.

DELAGENIÈRE reported ten cases of surgery of the bile passages, mostly abouching the gall-bladder through the rectus muscle in the anterior fascia of the muscle; one death. The cholecystostomy not only disinfects the bile passages and diverts the course of the bile, at least temporarily, but prevents any increased tension in the passages, thus avoiding rupture of the sutures and the escape of bile. Thanks to the fistula the sutures can be relied upon to hold.

ABADIE observed that section of the cervical sympathetic as theoretically indicated in a number of disturbances in certain organs caused by permanent excitation of the vasomotor nerves, leading to disordered nutrition, and that other affections besides exophthalmic goiter and glaucoma, may be found amenable to the same treatment. He added that we should study the morbid phenomena that may be determined in the viscera of the thorax and abdomen by the vasomotors of the sympathetic in these regions.

TEMOIN related an instance of fetal exaggeration of the symptoms in exophthalmic goiter consecutive to bilateral resection of the cervical ganglia.

JONNESCO reported six cures and four improvements in ten cases of exophthalmic goiter thus treated, adding an account of the excellent results attained in 45 cases of epilepsy and 7 of glaucoma with resection of the cervical sympathetic.

Next year the congress will discuss the questions: "Total Abdominal Hysterectomy," and "Tumors of the Bones," with addresses by Ricard, Pollosson and Berard.

SELECTIONS.

Shall the Consultant Pay the General Practitioner for Cases Referred to Him?—A contributor to the *Colorado Medical Journal* raises this question for discussion and argues for an affirmative reply as regards certain cases. His argument fails to satisfy the positive ideas of ethics of the editor of the *Philadelphia Medical Journal*, whose comment provokes a rather severe rejoinder in the first-named journal, and elsewhere the question is being taken up and discussed. The original proposer of the discussion, who shows his sincerity and earnestness by signing his name to his communication, argues simply that the general practitioner, before referring a case to the specialist, sometimes gives it a certain amount of attention, for which the patient will not pay him; and that therefore the specialist, who is benefited by such reference, should reimburse him. The rightfulness of paying for cases referred in this way must, however, be considered quite apart from the excuse of seeking by secret connivance to extort from an unappreciative patient, what may be rightfully due to his regular medical attendant. It involves more important influences and issues. There is reason to believe that it has been resorted to without any such plausible excuse; and by those who have not the manliness to avow such a practice, although they might hope that an avowal

would bring to them patients from such doctors as were willing to advise patients to go where it would be most to their own (the doctors') pecuniary advantage. While it may be a very small proportion of the profession who are liable to do any loose thinking on this subject, loose thinking does lead to loose practice, and on that account the subject is worthy to be generally discussed and to have its different aspects clearly presented. Even dropping all appeal to what are called higher motives, and considering it solely from the standpoint of selfish pecuniary interests, there is more than one side to the question. From the side of the general practitioner it may well be asked: Will the peddling of the patients prove permanently profitable? While it might be anticipated that there would be lively bidding among rival specialists, and that the young, inexperienced and ambitious would presently be willing to turn over the whole fee for the sake of experience and *eclat*, other things must be thought of. Can the general practitioner always land his patient in the net of the specialist who will charge the largest fee and share it most liberally? Can the transaction be repeated with the same patient or any of his friends? Will the patient so referred ever return to the general practitioner at all? Will not the specialist, instead of regarding the patient as leased, regard him as transferred in fee simple, and be shrewd enough to see that the way to recoup is by himself referring the patient to the next specialist, and so on until the patient can no longer be "referred" (sold), or is not worth "referring"? While the specialist may think it would pay to give a good percentage for patients, and so keep busy, gain experience, and come to be known as a rising specialist, instead of spending years of waiting in hard study of literature and the minute investigation of his few cases; while it may appear probable that the occasional reluctance of the general practitioner to give his patient the chance of benefit by the specialist's "superior knowledge and skill," would pass away under the influence of the proper percentage; while one might hope that the general practitioner with a direct pecuniary interest would be able to discover more cases of cataract, appendicitis or retroversion requiring operation, and even succeed in steering his neighbor's patients to his own pecuniary advantage, it must not be overlooked that the general practitioner who enters upon such a course may become too grasping—may prefer a larger fee to a smaller; and thus become the canvasser for the embryo specialist, or recent graduate who can afford to pay most for the opportunity to gain experience and advertise himself to the community. Then what will one's reputation be worth when the truth leaks out that it is built upon recommendations for revenue only? But when it comes to considering the scheme from the standpoint of the patient there ceases to be anything to consider, for no such plan can be put in operation with the consent of the patient. He will not knowingly pay indirectly through the specialist a fee that he would refuse to pay directly to his family physician; and if he knew that he was advised to go to a specialist who would divide the fee with his adviser such advice would not be worth giving. Only when all the parties directly concerned understand its nature, and agree to it, is a business transaction legitimate or honest. What is taken by stealth is stolen. If you claim that it is not theft to take what property belongs to you, the reply is that taking it by stealth always raises the presumption that it does not belong to you. The payment and acceptance of a fee from the specialist without the knowledge of the patient belongs exactly in the same category as collusion with the apothecary for a percentage on prescriptions. Only when the thing is done with the full knowledge of the patient can the referring physician rise from the level of a bunco-steerer to that of the paid agent or respectable drummer of the specialist. If any physician wishes to serve his patients as a professional adviser he must preserve his patient's respect and his own self-respect by openly demanding a proper recompense for his services, and properly enforcing that demand. He must not seek to obtain secretly and through the aid of another, what he is afraid or ashamed to ask openly. That would be a poor way indeed to dignify his calling and teach a proper respect for his services.—*Philadelphia Polyclinic*, December 3.

Hawking Physicians.—There may have been a time when the physician to some royal court found time and was permitted to engage in the sport of hunting with a hawk upon the wrist. Our present remarks do not apply to this kind of gaming, but to a less ennobling pursuit of crying one's wares upon the street or peddling them out for the highest price obtainable. Several of our contemporaries have had much to say of late upon the subject of commissions paid by specialists to general practitioners for cases referred to them. That there exists any very considerable amount of such reprehensible practice we are not inclined to believe, but that reference cases are at times paid for on the one side and the dividend freely accepted on the other is undoubtedly true. More's the pity. What has been called "bargain-counter" surgery, especially in the realms of abdominal and pelvic pathology, must have some existence in fact, or one would not hear of it from so many different sources. The blame has been placed almost exclusively at the door of the specialist, but one correspondent touches the keynote, it would seem, when he says that "country doctors frequently go about from surgeon to surgeon, seeking the highest bidder." It would not be surprising if equal blame were to be attached to him who has the case to sell and to the one who is willing to buy. It was some years ago that many reputable surgeons in this city were shocked in their finer susceptibilities by a down East doctor who landed in town with six laparotomy cases, which he proceeded to farm out on terms most advantageous to himself. Many of the surgeons approached had not before heard of such shrewd businesslike methods being applied to human existence, and very properly showed the visitor the door. Undoubtedly these surgeons would pursue the same course today. It is at least to be hoped they would. Whether or not this hawkster succeeded in finding an operator sufficiently devoid of ethical honesty to offer the proper "divvy" is not divulged. He may have taken the subjects to one of our neighboring cities, where so great a cry has gone up against the giving and accepting of commissions as to lead one to infer that the practice is much more prevalent than with us. Or he may have gone with his half-dozen protruding females back to his quiet New England village, and by operating upon them himself secured the whole of a smaller fee. Whatever may have been the outcome of the pilgrimage, the lesson must have been learned that because one man "sells" another does not always feel inclined to "be sold." Among the worst medical sins are to be reckoned those of commission. Physicians who indulge in such practices must sooner or later come to grief, and it would be better that both sides take warning before the patients discover for themselves that their welfare is being bartered and that they are likely to fall into the hands of incompetents willing to overcharge in order to pay exorbitant dividends.—*Medical Record*, December 3.

PRACTICAL NOTES.

Local Treatment of Neuralgia.—Apply, two or three times a day, the following mixture on cotton: Menthol and guaiacol, aa 1 gm., alcohol. absol. 18 gm.—*Vienna klin. Rund.*, November 13.

Motet's Operation for Ptosis.—Ptosis can be corrected by utilizing the synergy between the levator palpebrae and the muscles of the globe. Motet cuts a strip in the rectus superior and pulls it through a buttonhole in the tarsal cartilage to suture it to the upper lid.—*Gaz. Méd. de Paris*, November 12.

Scarlet Fever After Laparotomy.—A. Sippel reports a case of scarlet fever appearing in a virgin three days after laparotomy for an ovarian tumor; evidently the infection had occurred previous to the operation. He concludes from the favorable course and lack of complications in this case that it is unnecessary to defer an important operation, herniotomy for instance, in a scarlet fever patient, and that a child could be delivered

without being infected in simple scarlet fever.—*Munich Med. Woch.*, November 15.

Formaldehyde Disinfection.—Fairbanks states in the *Cbl. f. Bacteriologie* that raising the temperature of the room to be disinfected to 70 to 73 degrees shortens the time necessary for the disinfection. He used a Schering apparatus and found that bacteria were killed in eight hours, instead of requiring over twenty-four as previously.

Lupus Erythematoses.—Hebra reports remarkable success in six cases of this affection treated simply with alcohol applied on cotton, with which the surface is dabbed forty to fifty times. In each case the cure was prompt and complete, in spite of the chronic character of the lupus. Kohn has also applied it with success. Kaposi observed that the alcohol may have been the effective factor in the old spiritus sapon. kalin. Soap must be avoided while the alcohol is being used.—*Vienna klin. Woch.*, November 17.

Sign of Sclerosis of the Aorta.—Cherchovsky calls attention to a sign that will reveal sclerosis of the cross of the aorta even in its incipient stages. He has established that the arch of the aorta in normal persons has a variable dimension, as can be determined by tapping the region of the aorta with the percussion hammer five to ten times. The aorta dilates, and its increased diameter can be readily detected with the percussion. But if there is sclerosis the aorta remains unchanged.—*Semaine Méd.*, No. 51.

Heteroplastics for Prolapsus of the Brain.—F. Franke relates (*Cbl. f. Chir.*, November 26) his success with a celluloid plate with projecting ends, which he inserted under the edges of the skull to close the defect after operating on an abscess behind the ear, through which the brain matter was protruding with such tension that no sutures would hold. The celluloid plate held the brain substance in check for several weeks, when it was removed. The prolapsus had disappeared and a bone-skin flap from the regio supra-mastoides was applied with immediate and permanent success.

Potassium Chlorate for Burns.—Lutaud's method of applying chlorate of potassium to burns, for which it is being highly recommended of late, is: Open the blisters and apply cataplasms every four hours until the epidermic flaps are entirely detached. A sheet of cotton moistened with a solution of potassium chlorate is then applied and oiled silk over it. To prevent sticking to the wound a little glycerin is added to the solution or the chlorate is incorporated with lard; or, better still, Declat's glyco-phenique is used instead of the glycerin. The sedative effect of phenic acid on burns is remarkable.—*Jour. de Méd. de Paris*, November 20.

Water Gymnastics.—Von Leyden and Goldscheider emphasize the importance of the effects attained in cases of atrophy of the lower extremities, painful joints, etc., by a series of gymnastic exercises performed under water, which should be at a temperature of 28 to 32 degrees R. The sensation of weight and resistance is removed and the buoyancy imparts both a physiologic and psychic stimulus of great value. An attendant holds the trunk still, if necessary. If able to stand, the exercises are best performed in an erect position, the body supported.—*Deutsche Med. Woch.*, November 17.

Vomiting of Pregnancy.—Barth observes that uncontrollable vomiting in pregnancy depends upon two factors in varying proportions; a nervous influence emanating from the uterus and reflected upon the nerves of the stomach, and an auto-intoxication from defective function of the liver. The clinician should carefully inform himself in regard to the pathologic part of the patient as soon as possible, as temporizing is criminal when there is an evident hepatic lesion. In such a case, if an exclusive milk diet and oxidating medicating do not control the vomiting, then there is but one thing to be done, i. e.,

arrest the pregnancy and at once, before the auto-intoxication aggravated by the digestive disturbances and inanition has time to produce irremediable disorders in the organism.—*Semaine Méd.*, November 16.

Euphorbium in Surgical Tuberculosis.—Pénidres announced a year ago that he had been very successful in curing local tuberculous processes with an emulsion of the gum resin, euphorbium. He now states that experience and time have only confirmed the great value of this simple treatment, particularly in monoganglionic adenitis, which is usually cured with two or three injections. One striking case is a girl of 14 years, who had an enormous poliadenitis on the right side of the neck, almost inoperable. The left side had been similarly affected, but had been operated several times and was seamed with scars. The tumor compressed the ear, causing deafness; its surface was covered with suppurating fistulous openings, and even respiration was impeded, but the case was entirely cured in a few months with a dozen injections of the euphorbium, made very irregularly. The tumors and deafness disappeared, and the skin became white and supple.—*Gaz. Méd. de Paris*, November 12.

Gastrotomy.—Urban reports a case of carcinomatous degenerated stomach entirely removed; smooth recovery; no disturbance in digestion; woman of 35 years (*Munich Med. Woch.*, November 22). Perier recently presented before the Paris Academy of Medicine a patient operated on a year before for a neoplasm requiring excision of the middle portion of the stomach and of the transverse mesocolon. He then united the two cul-de-sac left after this annular excision, with a double suture reinforced by a lining made of the omentum. She has gained 13 kilos in weight, appetite is good and digestion easy. Constipation is controlled with cascara and injections daily. He emphasized the necessity of pushing down and away from the field of operation the fecal matters in the colon. By pushing the contents of the distended colon down to the sigmoid flexure, he was able in the course of three days, with numerous injections and suppositories, to secure a copious passage, after which the patient rapidly improved, although her condition had been quite precarious before. He ascribes to the ignorance of this necessity his failure in another case which promised equally well. He concludes his communication with the advice to push the contents of the intestines during a laparotomy well down into the rectum, when the accumulations indicate any difficulty of evacuation.—*Bulletin*, November 15.

Sulphuric Acid in Infections.—Noskowski states that sulphuric acid is extremely effective in arresting infections, on account of its property of absorbing oxygen. Bacteria in general are unable to live without oxygen, and where it is lacking they procure it by decomposing organic substances, if possible; if not, they die. Sulphuric acid also obtains it from the same substances as the bacteria, and introduced into the organism it absorbs the oxygen, which stimulates the hematoses, respiration, circulation and the organic exchanges, thus depriving the bacteria of the oxygen they require and also stimulating the organism to repel their invasion. He finds that animals can take 25 milligrams of sulphuric acid per kilogram without injury, in a subcutaneous injection. His method with man is small rectal injections of 10 centigrams of nascent sulphuric acid made by dissolving in water a sulphid and an organic acid, fractioning the dose as desired. Infants can take 10 milligrams every two hours, increasing gradually to the age of 8, when the dose can be 10 centigrams, as for an adult. One to six of these injections will certainly cure intestinal infections in young and old. Three to twelve injections are necessary in typhoid fever, eruptive fevers and influenza. Even in advanced tuberculosis they will prolong life many years, and in fresh cases have resulted in a few cures. He has inhaled in a gaseous form in pulmonary affections.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	2 00
Single Copies	10 Cents

In requesting change of address, give old as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, DECEMBER 17, 1898.

STUDIES OF THE COLON BACILLUS.—COLON
INFECTION OF THE URINARY TRACT.

The colon bacillus has been found in connection with a large number of diseases, but whether it can be stated to be the real cause of many of these processes is still an undecided question. There are as yet great difficulties in the way of accurate identification and classification of bacteria, as witness the so long confused relations between the colon and typhoid bacilli. Only recently has it been possible, by means of PFEIFFER's phenomenon (Widal's reaction), to show that there is a fundamental difference between these two organisms.

A large number of the investigations bearing on the colon bacillus are of little value, because of the incomplete descriptions of the forms of growth and other biologic characteristics of the bacilli studied. RAHLFF¹ attempts to draw a clear picture of the typic colon bacillus and its biology. For this purpose he cultivated sixty-two different kinds of this microbe, partly from the feces, partly from pathologic products.

He describes the typic colon bacillus as follows: It is decolorized by GRAN's method; does not liquefy gelatin; it decomposes lactose and glucose, and grows quite luxuriously on different kinds of potato. It does not decompose urea, but among the author's sixty-two varieties there were two which decomposed urea, one of these coming from the feces, the other from urine containing pus. There are numerous microbes that resemble the colon bacillus, but differ in one or more points from the typic organism. Con-

sequently, all investigations concerning this bacillus or allied forms should definitely specify the morphologic and biologic characteristics.

The forms which RAHLFF has studied were obtained partly from normal feces, partly from pus in perforation peritonitis, and also from purulent urine. In many cases one variety was obtained from the normal excretions, and another from the pathologic product. The virulence was determined in a large number of cases by intraperitoneal injections into guinea-pigs. It was found that the colon bacilli from the normal feces, as a general rule possessed the same nearly constant degree of virulence, whereas the bacilli that were obtained from the urine varied very much, some being more virulent, others less virulent than those isolated from the feces of the same individual.

Among the large number of disease-processes with which the colon bacillus is more or less closely connected, the author has selected for more extensive study, infectious processes in the urinary tract and perforative peritonitis. Previous investigations in regard to the infections of the urinary tract are undoubtedly vitiated in many instances by two distinct sources of error: the first one is, that urinary, especially tube, cultures from fluids and organs containing colon bacilli and other bacteria very often yield but one growth, namely of the colon bacilli, which have the power of preventing by overcrowding the growth of other bacteria. In such cases, microscopic examinations, careful study of smears, and various technic aids must be employed in order to demonstrate the possible presence of microbes which the cultures do not bring to light. In these cases the primary cultures should always be made by the plate method. Another source of error is to be watched for in examinations in regard to the presence of colon bacilli in dead bodies. It may be regarded as fairly well established, that the colon bacillus may migrate in large quantities into parenchymatous organs, not only after death but also during the agony, and that when found outside the digestive tract under such circumstances the colon bacillus has undoubtedly incorrectly been regarded as the cause of the perhaps fatal illness.

In agreement with the claims of ROVSING, RAHLFF insists that the colon infection of the urinary tract is essentially a benign process. The colon bacillus but rarely attacks the bladder; the kidney and the pelvis are however, often involved, being the seat of the primary infection, which may descend along the ureter. The colon infection of the kidney and renal pelvis is described clinically as of rather sudden beginning, with fever and chills; at times severe and persistent, at other times less well marked, lumbar pains; and a constant diarrhea. Often the urine is burning: there may be vesical tenesmus, and the urine, which is acid, will be found to contain more or less pus and numerous bacteria. Objectively, there is usually a marked tenderness in the region of the

¹ Studier over colibacillen, 1898.

kidneys. The attacks subside very generally without any treatment, except that the urine may continue opalescent and free of bacteria for a longer or shorter time, while the patients have otherwise apparently regained perfect health. The author believes that the more severe cases depend upon a gastro-intestinal disturbance, which is shown by the very nearly constant diarrhea, and that from the intestinal tract the colon bacilli pass into the blood and become localized in the kidney and the pelvis. In many cases a pre-existing nephrolithiasis seems to favor this localization. It is very probable that the local renal infection occurs during the process of elimination through the kidneys.

OYSTERS AND DISEASE GERMS.

There are probably few persons of any taste who doubt the wholesomeness of oysters, though the question has been raised and extensively discussed in times past. In the light of modern germ theories it again comes to the front, and the possibility of their conveying disease has to be seriously considered. Three or four years ago an epidemic of typhoid among the students of an eastern college was credited to the ingestion of oysters that had been taken from sewage contaminated water, and some similar experiences in Great Britain led to the appointment of a committee of the British Association for the Advancement of Science to investigate the matter and report results. This committee, consisting of Professors HERDMAN (chairman), BOYCE and SHERRINGTON, Dr. C. A. KOHN and Mr. G. C. BOURNE, has this year made the third and final report, the substance of which is given in *Science* of November 27.

In a previous report the committee had already called attention to the presence of organisms in oysters closely resembling the bacillus coli communis, and also of others varying somewhat in their reaction from this species, and strongly suggestive of Eberth's bacillus, and a comprehensive Local Government Board Report of Dr. KLEIN had likewise done the same. Their later researches, which were not solely confined to oysters, but included other edible mollusks, mussels, periwinkles, whelks, etc., as well, are only confirmatory of these earlier ones, while their additional thoroughness and completer methods give them a decidedly greater value. In nineteen samples of oysters from various sources there was found in nine a bacillus closely resembling *B. coli*—in some cases almost a pure culture was obtained with characteristic odor. The reactions differed; in one group they were typic, acid, coagulating milk, giving out indol and gas, and the growth on potato was luxuriant. In another group, however, there was a very actively motile bacillus that did not coagulate milk, gave out indol and gas bubbles only occasionally, and had in three cases an alkaline and in two a slightly acid reaction. Serum tests were negative, and from all the

facts the committee concluded that it could hardly be identified with the true typhoid bacillus.

In the earlier reports of the two previous years the committee had given the results of experimental infection from oysters, and in the present one they recommend, in view of the existence and frequency of microbes of the colon type in these as well as in other species of shellfish, that steps be taken, either by Government inspection or by co-operation amongst the dealers, to remove any possible suspicion of sewage contamination. It has been proven sufficiently that oysters can imbibe sewage, and the source of the contamination being proved, the danger is a real one. They recommend the formation of an association of oyster dealers who, for the credit and safety of the trade, will look after the sanitary requirements and provide for periodic examination of the oyster beds, with special reference to their needs. They seem to think that there is little danger in oysters from pure sea water, at least so far as regards these disease germs; the peril of sewage infection lies therefore, mainly in the fattening beds, which are apt to be in fresh water or tidal creeks, and in oysters taken from estuaries and rivers that receive the sewage of thickly populated territories.

There does not appear to be any evidence given, at least in this final report, that sewage necessarily affects the mollusk itself—it may be that it thrives on it—but it none the less may be a dangerous source of infection to its human consumers. The committee report, however, touches upon another possible cause of unwholesomeness in these articles of diet or luxury, that is due to a disease of the oyster itself. A green coloration of oysters has long been observed to occasionally occur, and has, in times past, been attributed to copper and occasionally supposed to render the oyster unfit for consumption. There has been, however, no really authoritative utterance given out, and green oysters have often enough been eaten without serious consequences. The committee investigated this phase of the oyster question also, and find that while a green tinge is not always an indication of the unfitness of the mollusk for human food, it is in some cases associated with a diseased condition, leucocytosis, and that such are not to be recommended. It would appear that there is room for further study on this subject, especially in this country, for their researches were apparently confined to European oysters or to American oysters transplanted to European beds. The report does not aid us over here to decide what green tinted oysters are wholesome and what are not; we are left in doubt as to the whole class.

It would be well if those States in which the oyster fishery is an important industry could utilize the suggestions of this report in some legislative act that would tend to secure the public against possible dangers from contamination of this very important and

popular form of sea food. Oyster cultivation is or should be a very important local industry along our coast, but it ought to be under regulation. If oysters fatten in sewage infected streams, this ought not to be permitted to be a temptation to ignorant or unscrupulous breeders, and local government regulations should control the choice of the beds as well as their working. There is an opening for the labors of a State bacteriologist in each and all of the oyster-producing States, sending out as they do a food product so popular and so generally eaten raw or imperfectly cooked and thus especially liable to convey any existing germs of disease.

AUTO-INTOXICATION AND NEURASTHENIA.

The relation of uric acid to neurasthenia has been long ago suggested, but has not entered definitely into the pathology of the disorder. Ordinarily we are or have been inclined to accept the action of the fatigue and exhaustion of the nerve-cell as the principal factor in its production without specially looking further for the influence of morbid metabolism in its production. Nevertheless, in these days, when auto-intoxication is invoked so often as a cause of disease, neurasthenia could not well be overlooked, and certain French authorities, notably among them VIGOUROUX, have maintained that neurasthenia and the arthritic diathesis are closely connected, if not merely differing manifestations of the same general disorders of oxidation and tissue change. In this country we have recognized a disorder the majority of the symptoms of which are essentially neurasthenic—lithemia, as the common American manifestation of the gouty constitutional vice—thus admitting, to a certain extent at least, that auto-intoxication may give rise to these characteristic symptoms. The presence of uric acid in excess in the urine of neurasthenics has long been noted, and the relations of the gouty diathesis to the condition have been admitted by some neurologists who, like DERGUM, for example, are inclined to admit a toxic factor in its production.

An important addition to the literature of the subject is contributed by BECHTEREW, the well-known Russian investigator of the physiology and pathology of the nervous system, in the *Neurologisches Centralblatt* of November 15 last, under the title of "Ueber Störung des Stoffwechesels bei Neurasthenie" (The Disorders of Metabolism in Neurasthenia). He has had for a considerable period, examinations and analyses of the urine of neurasthenic patients carried on in POEHL's laboratory, and found that neurasthenia, sometimes at least, appeared to depend upon irregularities of oxidation. In general, and especially in the severer types of the disorder, there was a more or less marked decrease of urea and an increase of uric acid. The proportion of the general nitrogen in the urine to that in the urea—which, according to POEHL, is the coefficient of the oxidation energy and the expression of the tissue

respiration—indicated a constant and notable decrease of nitrogen oxidation. The proportion of uric acid to phosphoric acid, in the form of its di-sodium salts, showed an increased cleavage of uric acid and led to the conclusion of the presence of a more or less pronounced uric acid diathesis.

In the severer cases of neurasthenia BECHTEREW also found that the proportion of general nitrogen to phosphoric acid, which according to SULZER indicates the decomposition energy of nerve tissue, seemed to be increased, and the same was true to some extent as to the proportion of general phosphoric to the amount of glycerophosphoric acid, which according to LEPIN, indicates lecithin decomposition. In many cases also the quantitative ratio of sulphuric acid to the aromatic sulphuric acids that serves as the index of intestinal putrefaction appeared more or less markedly increased.

From these results, BECHTEREW believes that neurasthenia is associated with irregularities of oxidation of nitrogenous substances in the organism and that it must therefore be classed with the other disorders due to and associated with disordered general metabolism. The chief cause is, he thinks, an intestinal auto-intoxication, a more reasonable theory than that of gastric dilatation suggested by VIGOUROUX. He does not, however, exclude other predisposing causes of neurasthenia, such as mental strain, etc., which may have their influence in the causation of the intestinal disorder. There is a wide field for research yet in the action of the fatigue poisons, especially in the nervous system, and this may carry us back to still more remote factors in the etiology of neurasthenia. When once intestinal putrefactive poisons are absorbed, however, there may be ample reason for even severer disturbances of the nervous system; the part they play in the causation of some forms of insanity is probably an important one.

There is something in the suggestion thrown out by BECHTEREW, that mental overwork and sedentary habits may divert the proper blood-supply of the intestines to some extent and thus embarrass their functions and lead to stasis and absorption of toxic material, and also that shock and other occasional causes of nervous asthenia may act through the vasomotor system. Whether we are justified or not in accepting his conclusions, his facts are valuable additions to the sum of our knowledge as to the conditions associated with neurasthenia, and their suggestions are perhaps still more valuable. They throw additional light on the relation existing between arthritism and neurasthenia, one that must have suggested itself many times to any one with a practical acquaintance with these conditions and one which, though disbelieved in by some authorities, appears to be more and more forcing itself upon our attention. Whether we are to consider them identical in their etiology and pathology is one thing; the recognition of their intimate relation is perhaps another.

ABERRANT FORMS OF CHRONIC LEAD-POISONING.

It has been well said by one of the great teachers in medicine that when a patient comes before the physician with obscure symptoms in connection with the nervous system, indicating organic disease, two conditions should always be thought of as the possible exciting cause: syphilis, and chronic metallic poisoning in some one of its forms, usually in the form of lead. This dictum arose from the fact that syphilis is competent to produce almost any lesion in the body, and that lead often manifests its presence by conditions which are so unusual that its presence as an exciting cause is not suspected. It frequently gains access to the body in a manner which does not raise suspicion, as for example, in the well-known epidemics of plumbism that have arisen from the use of previously pure water delivered through lead pipes, the attacks of "dry cholera" so-called which have followed the use of flour ground in mills in which the stones had been "filled" with lead, and again, as in two cases which have come under our notice, it has gained access to the body owing to the fact that seamstresses make it a habit to chew small particles of thread which they bite off when threading their needles which thread when, it was made of silk, was sometimes loaded with lead to increase its weight. By this habit of chewing leaded threads enough of the poison was taken into the body to produce saturnism.

It is also becoming a well-known fact that nothing is more easy than to make an erroneous diagnosis of locomotor ataxia when in reality the condition is one of plumbic peripheral neuritis, or pseudo-tabes, and these difficulties in diagnosis are increased not only by the facts that we have mentioned, but by the additional discovery, which is becoming more and more clear each year, that the manifestations of chronic lead-poisoning may not appear for a long time after the patient has been exposed to the poison. Thus we have recently seen a case in which the symptoms of lead-poisoning did not come on for six months after a painter ceased working at his trade, and several cases of this character have been reported recently in the *Birmingham Medical Review*, by KAUFFMANN, in which the patients presented symptoms of lead-poisoning a number of months after being exposed to the poison, in one instance after almost two years. An analysis of the urine in these cases showed the presence of lead, proving that the diagnosis of the cause of the symptoms was correct.

The manner in which this curious delay occurs is not far to seek when we study the question of the elimination of lead. It is a substance which is eliminated from the body very slowly indeed and, like other metals, has a tendency to accumulate in the tissues, where it forms a fairly stable combination with the protoplasm, and probably also with uric acid, as is illustrated in the development of what has been

called "plumbic gout." Further than this, almost every tissue of the body seems to be capable of containing it, though the muscles and blood contain less than any other part. In many instances it is evident that these delayed symptoms arise from the gradual deposit of lead in the tissues during the period in which the patient is in a condition of good health and nutrition, and that later on, when by reason of illness, bad food, or unsanitary surroundings, a portion of the protoplasm of the body is utilized for vital processes, the lead which has been deposited is picked up once more by the blood and lymph streams and distributed to the tissues, where it produces its effects. This matter is not only of importance from a medical point of view, but also because interesting medico-legal questions arise in connection with it. Thus, for example, a suit might be brought upon the part of a person who had been unwittingly exposed to lead with the development of symptoms a number of months afterward, and the defense might claim that it was impossible for so long a period to elapse between the exposure and the development of plumbic symptoms. The cases that we have cited show, however, that this would be competent defense.

BOOK NOTICES.

Transactions of Iowa State Medical Society. Vol. v. Cloth. Illustrated. Pp. 425. Burlington: Keehn-Harper Mfg. Co. 1898.

Besides the minutes of the forty-seventh annual session of this Society, the volume contains forty-eight papers and addresses presented before the Society, with obituary notices and portraits of Drs. Elizabeth Hess, Henry Clay Bulis, Walter Oscar Richards, R. H. Moffit and W. A. Todd. There is also a list of the permanent members of the Society, the Iowa delegation to the Denver meeting of the AMERICAN MEDICAL ASSOCIATION, a list of exhibitors and auxiliary medical societies.

Annual Report of Health Officer, Port of New York. Paper. Illustrated. Pp. 100. New York and Albany: Wynkoop Holtenbeck Crawford Co. 1898.

This, the report of Health Officer A. H. Doty, is that for the year 1897, transmitted to the Legislature March 30, 1898. Some of the topics considered are: "Inspection of Passengers and Crews of Incoming Foreign Vessels;" "Disinfection by Steam;" "Formaldehyde as a Disinfectant;" "Formaldehyde with Special Reference to its Chemistry in Disinfection;" "A Preliminary Note on the Investigation of the Antitoxin of the Bubonic Plague," and "Notes on a Yellow Fever Prophylactic Fluid."

Transactions of Pathological Society of Philadelphia. Edited by WILLIAM S. CARTER, M.D. Vol. xvii. Paper. Illustrated. Pp. 493. Philadelphia: Wm. J. Dornan. 1898.

This volume contains the report of the Society's proceedings from October, 1895, to June, 1897, and contains lists of former presidents, officers, committees and members. The contents are classified under the several heads: Diseases of the osseous system, of the digestive tract, of the cardiovascular and hemopoietic systems, of the respiratory tract, of the genito-urinary system, of the nervous system, and diseases of the ductless glands. There is also a chapter on miscellaneous matters and one on technic.

Transactions of Medical Society of West Virginia. Paper. Illustrated. Pp. 235. Wheeling: W. J. Johnston.

This volume contains the proceedings of the thirty-first annual session of this society, held at Martinsburg, W. Va.,

May 18-20, 1898. There is also a "Report on New Remedies," and papers on: "Diabetes Insipidus, with Cases;" "Exophthalmic Goiter;" "Fracture of the Patella; Treatment by Mediate Ligation," and "A Brief Review of Theo. Durrant's Case."

Journal of Proceedings of the National Pure Food and Drug Congress. Paper. Pp. 54. Washington, D. C. 1898.

These proceedings are for the Congress held in Washington, D. C., March 2-5, 1898, and comprise the many addresses and papers presented at this session.

PUBLIC HEALTH.

Book-Holder for Schools.—The Giessen High School provides each pupil with a simple, cheap, adjustable little book-holder to stand on the desk and hold the book open at the proper angle, made on the principle of a folding photograph case.—*Deutsche Med. Woch.*, November 17.

Health of Indiana.—The reports for November indicate an increase over the preceding month, in area of prevalence, of tonsillitis, bronchitis, rheumatism, pneumonia, scarlet fever, pleuritis, inflammation of bowels and erysipelas. Decrease is indicated in intermittent fever, influenza, diarrhea and dysentery. Typhoid fever and diphtheria remained unchanged.

Intoxication from Meat.—Salchow reports five cases of intoxication following the ingestion of some freshly purchased corned meat. In two cases vomiting was the only symptom, but the three others, children, presented every symptom of severe poisoning with atropin or a similar alkaloid. All recovered in ten days.—*Deutsche Med. Woch.*, November 17.

Army and Navy Mortality in Life Insurance.—The mortality in the British army and navy, under modern war conditions, has been analyzed by the secretary of a large life insurance company. He found, to begin with, that the selection of men for entrance into the navy is so severe that in the first year the standard of health is considerably higher than among a body of insured lives in the first year of insurance. He concludes that 6.1 per 1000 is the extra mortality rate which, for life insurance purposes, may be considered as incident to service in the navy, and that 9.9 per 1000 must similarly be rated as the extra hazard for army service. He figures up these extra rates thus, taking as the observed period the ten years, 1886-95. In the army the extra rate among active lives in the whole force was 4.7 per 1000 while in the navy it was only 1.8 per 1000. But the risk of death in active war service was 3.8 per 1000 in both army and navy, from the standpoint of life insurance. He quotes from Smee to the effect that "after carefully weighing the available data, and giving consideration to the conditions of modern warfare, and the present strength and efficiency of European armies and navies, and also to the diminished mortality in respect of climatic risk, we propose, for the purposes of the report, to estimate that the British army and navy will be engaged once in forty years in a national war, involving the calling out in active military service for a term not exceeding three years of two-thirds of the whole force of officers and men in both branches of the service"; and Lord Rosebery, speaking before an association of commercial bodies some weeks ago, reminded his hearers that the country is in an epoch of danger, not having been engaged in a European war in forty years past. Among British naval stations, the Mediterranean has the highest death rate, 10.6; the North American and West Indies station has the lowest, 5.1; in the East Indies station the extra mortality rate for insurance purposes was 7.0 in the five years, 1886-90, and 5.8 in 1891-95; the average for all stations is 7. The insanitary condition of the Mediterranean station is chargeable to filthy towns and harbors, but this is improving. The extra rate in the army has also declined from 10.6 in 1886 to 5.5 in 1896.—*The Independent*, November 24.

Obstacles to Sanitary Service.—In the October issue of *Public Health* (London), a curious instance is related of unrequited faithfulness on the part of a health officer, located in the west of England, who ran counter to the wishes of a local politician, who was chairman of the district committee. In the family of the latter a child was found to be ill of scarlet fever. When the health official began to inquire into the origin of the infection the medical officer found that another child in the house had been ill in bed for a fortnight, and was desquamating freely. The latter case had not been notified, which fact was reported to the Council. At the same meeting, the medical officer had to report that the child of a neighbor had been sent to school within a week of being taken ill with the same disease, and that this case also had not been notified. When the report came to be considered, a single proposition was made to prosecute in both cases under the Notification Act. According to the newspaper report, the chairman, one of the offenders, did not leave the chair, but remarked that he had a complete answer to the charge. It appears from the report that on a vote being taken no one opposed the proposal, nevertheless, the chairman, at a subsequent stage of the proceedings, declared that the proposal had been lost. On this declaration being disputed, a second vote was, by leave of the meeting, taken, and the voting was then equal, whereupon the chairman gave his casting vote for quashing proceedings against others as well as himself, and placing the health official at a signal disadvantage as to his future official course. It is not easy to think that such a disgraceful bit of jobbery can be matched, and all sanitarians would be pleased to learn that the superior governmental authorities have taken the case into consideration. A question arises whether the chairman has not laid himself open to proceedings for a much higher penalty than that provided for under the Notification Act. So far as the district in question is concerned, legal proceedings against other offenders must be an impossibility. The unfortunate medical officer of health had the courage to report to the council the neglect of its chairman to notify the first case in the family, but being in private practice, has probably very materially injured his patronage.

An Efficient Woman's Health Society.—The last annual report of Dr. J. Niven, health officer of Manchester, England, says that no report on the sanitary work of the Manchester Corporation would be complete which did not include some reference to the work done by the Ladies' Health Society in the poorer parts of the city. This organization concerns itself partly with social and partly with sanitary matters. Established as early as 1862, it has of late appeared to grow in strength and influence. That portion of the work in which the society comes in relation with the health office is carried out by health visitors, who are employed, guided, and assisted by the ladies who form the society. The female health visitors live in their respective districts, and are at the constant call of the people for help and advice in cases of emergency. They visit the houses systematically—six hours a day, except Saturday—and a report of their work is received each morning by the health office. They supply lime in suitable cases for purposes of lime washing, and lend out Turk's head and flat brushes for use. One visitor alone during the last twelve months has had fifty bedrooms, and numerous sculleries, cellars, yards, and closets thoroughly limewashed by the tenants. They supply carbolic soap to poor people at 2d. a pound, or 5d. a bar of three pounds, which is used in the cleaning of their houses, giving away a little at their discretion. In those cases where soap is supplied free, the health visitor sees that it is applied to the intended purpose of cleansing the house. The cleaning of floors, burning of refuse, washing of clothes, and other points of the same kind, are matters of great moment to health, in which the health visitors give much useful instruction. The

visitors carry with them disinfecting powder, explaining its use, and leaving it where necessary; at the same time they make a record of any dangerous condition discovered. An important part of their work is that which is devoted to the interests of children. They call attention to bad clothing and neglected conditions, and do what they can to remedy what is wrong—sometimes even dressing the children in case of neglect, and giving clothing in suitable cases of want. They give systematic instruction on infant-feeding. They also instruct the mothers, in a precise manner, how to keep the children's heads clean, and see that it is actually done. They fulfil an important part in the distribution, and oral explanation of printed instructions on feeding children, and on the steps which a householder must take to keep his family in good health. In the last annual report of the health officer the results of an inquiry which they made for him on infant-feeding is given. It is largely through them that a knowledge of the contents of handbills on sanitary matters becomes known to the poorest class. They also visit, on behalf of the medical officer of health, the homes at which deaths have occurred, except from any infectious disease, and fill up the card supplied to them in each case. They also do other work of a very useful nature, such as lending out maternity-bags to poor people, and, in cases of general illness, sheets, night-dresses, pillow-cases, etc. In summer the health visitors recommend suitable children to the Children's Holiday Fund, and see to the cleanliness of the children before they go for the holiday. In 1890 the Corporation paid the wages of six of these female health visitors; they now pay the wages of nine.—“Annual Report,” 1897.

A Model Water-Plant Village.—The *Sanitary Record*, London, describes a village built up for the accommodation of the workmen and their families, who are employed upon the new waterworks of Birmingham. That city has entered upon an expensive undertaking in order to protect itself against the commercial and sanitary embarrassments of water-scares, having secured vast water-bearing territory in Wales for the purpose of having ample reservoirs. The “model village of Birmingham,” as it is called, has been built for those employed upon these works, and the details are worthy of note by all interested in the carrying out of great works. The houses are built of wood, and the village is approached by a suspension bridge. The advantage of this is that “strangers” have to state their business before they can find a way into the place. If they are seeking work a night must be spent in the corporation “doss-house” on the opposite side of the bridge. Here they must strip and have a bath; during the night their clothes are disinfected, and in the morning the applicant has to appear before the resident medical officer. If everything is satisfactory a permit is given to cross over, and by this means a clean bill of health is maintained. The village itself, to quote from the article we have referred to, is laid out in streets, the house blocks being specially designed, as the case may be, for the accommodation of single families or for the housing of a limited number of unmarried men lodging with a married couple. In the latter case each lodger has his own separate cubicle and locker, and enjoys the use of a living room in common with the other inmates of the house. The villagers number some 1500 navvies and others employed on the work, with their wives and families. Baths and wash-houses have also been built, a large public assembly-room, a canteen and general store, a postoffice and a police station. A medical officer and a staff of trained nurses are associated with the infirmary hospital down near the work, and the isolation fever hospital up on the hillside, away from the abodes of men; and a chaplain and missionary look after the principal well-being of the settlement. This small town is only a temporary arrangement; that is, when the work is finished it will be removed, yet the sanitary provision made is as complete as for any permanent

town. A constant water-supply is laid to all the houses, and fire hydrants are placed in the streets. These derive their supply from a temporary reservoir in the hills behind. The main drainage and sewerage works are complete in every particular, and the flushing of the street sewers is carried out on “an original and unique plan,” calculated, we are told, to ensure the absolute cleanliness of the system from end to end. Advantage is taken of the natural fall of the river, the engineers having laid the main pipe through the village parallel to the river, and continued it up stream till it taps the river-flow at a point above the highest house in the settlement. Thus a constant stream of pure river water is day and night scouring through the full length of the drainage system, and discharging into the settling tanks down the valley below the village. Thence the clarified sewage, very dilute, passes back into the Elau. In addition to all these excellent arrangements, a line of rails has been laid from the village to the works. After the train has taken the men to their ground it returns to the village and conveys the children of the colony to a school, three miles away.

Decline of Vaccination in England.—The antivaccinationists are commonly regarded as a “feeble folk,” not a most irrational body, peculiar to or but little known outside of the Anglo-Saxon race. They may be feeble intellectually or logically, from the point of view of the medical majority, but they have been powerful enough politically to increase the numbers of the unfortunates who are susceptible to variola, as well as to stifle the best instincts of the British law-givers. According to the twenty-fourth annual statement of the officials appointed under the act requiring compulsion in England regarding vaccination of infants, passed in 1871, we may believe that in 1872 the proportion of unvaccinated persons in London was 8.8; in the rest of England, 4.5. In 1875 the proportion was as low in England generally as 3.8, but since that time the number has increased until, in 1895, the figure for England and Wales was as high as 20.5. Of the 921,512 births returned as registered during the year 1895, deduction was first made of the deaths that took place before vaccination; of the survivors, 816,682, there were registered 76.5 per cent. as successfully vaccinated, 0.4 per cent. as either insusceptible or as having had smallpox and, including 1.7 per cent. as under medical certificate of postponement, and 23.1 per cent. as at that time not finally accounted for as regards vaccination. The proportion of cases not finally accounted for in England and Wales for 1895 is 20.5 per cent.; in the metropolitan returns for 1895, 24.9 per cent.; in the provincial returns 19.8. It is thought by the editor of the *Scalpel* in the issue for October, that a want of care has caused the unpopularity, if it really exists, among the poor of England concerning the best-proven remedy for that terrible disease—smallpox—and only by a greater degree of care on the part of every practitioner of the holy art of vaccination can the medical profession go forward in the line of life saving pointed out by Jenner. So far as lymph is concerned the vaccinator is enabled to say that in the new glycerinated bovine lymph, it has the best that the ages have yet produced, probably better than that which Jenner himself had to operate with. A very plausible objection to vaccination has been removed by the introduction of this relatively aseptic material. A common-sense view of the question appears to be that it is distinctly unfair to the better-educated majority that it should through the faddist opinions of a small and ignorant majority, be exposed to the dangers of a pestilence like smallpox, and it is probable that if instead of abandoning compulsory vaccination, those in authority in England had firmly stood out against the agitation and had resolved to enforce the law strictly, the movement against it would have died a natural death. At any rate, it seems safe to make the assertion that this country and other nations who have become convinced by experience that vaccination is a safeguard against the ravages

of smallpox, will be chary of following England's lead and of trying what Lord Lister calls "a tremendous experiment." It is interesting to note that Scotland and Ireland refuse to have the new law put into operation within their borders, and that the English Government *does not intend to alter the existing regulations in regard to vaccination in India*, thus plainly showing that in the case of England it is taking steps at variance with its better judgment, as regards its own population; thus giving to its latest legislation upon the subject the color and form of a cowardly compromise and an insincere homage to a sanitary science, falsely so-called.

SOCIETY NEWS.

Medico-Chirurgical Society, Louisville.—The regular meeting of this society was held at Seelbach's Hotel, December 2, as the guest of Dr. L. S. McMurtry, who read a paper on "Endometritis."

Nelson County (Ky.) Medical Society.—Among the papers to be read at the regular meeting of this society are: "The Nausea and Vomiting of Pregnancy and Its Management," by J. B. R. Cooper, Samuels; "Chronic Glandular Enlargement and Its Treatment," by S. B. Crume, Bloomfield; "Some Difficulties in the Catheterization of the Male Urethra," by A. G. Blincoe, Bardstown; "Puerperal Eclampsia," by W. S. Napper, Boston. Dr. B. E. Gore of Bardstown, is president, Dr. J. W. Hill Jr. of Boston, secretary.

International Congress of Gynecology and Obstetrics.—This Congress is to be held at Amsterdam, Aug. 8 to 12, 1899. The subjects appointed for discussion are: 1. "Surgical Treatment of Fibromyomata." 2. "The Relative Value of Antisepsis and Perfected Technique in the Present Results of Operative Gynecology." 3. "Influence of the Position on the Shape and Size of the Pelvis." 4. "Indications for Cæsarian Section." The official languages will be English, German, French and Italian. The addresses, translated into these languages, will be delivered to the members a month before the opening of the Congress.

Mildraugh Hill Medical Society.—The regular meeting of the society was held at Elizabethtown, Ky., December 8, with Dr. C. Z. Aud as president and Dr. E. Smith as secretary. The following papers were on the program: "Some Points in Obstetric Practice," by W. A. Ligon, Sonora; "Bright's Disease of the Kidney," by Stinson Lambert, Owensboro; "The Care of the Patient in Typhoid Fever," by B. M. Taylor, Greensburg; "Some Suggestions Concerning the Treatment of Typhoid Fever," by D. W. Gaddie, Hodgenville; "Brain Surgery," by W. C. Dugan, Louisville; "The Prevalence of Errors in Refraction," by A. G. Blincoe, Bardstown; "Diphtheria, with a Few Notes on Cases in Point," by D. C. Bowen, Nolin; "Lavage of the Stomach," by J. T. Green, Leitchfield; "Indigestion," by F. A. Barnett, Lebanon Junction.

Philadelphia Neurological Society.—At the last meeting, Dr. H. C. Wood exhibited two cases of myopathy, which seemed to have exerted itself on several members of the same family. The woman was of middle age, the muscles of arms seeming to be of normal rotundity, but with tender spots in certain areas. Areas of anesthesia also existed in various portions of the body, in both cases. In the man, the patellar reflexes were mostly exaggerated and ankle clonus was marked. In both cases the gait was awkward, almost causing the patient to fall. Dr. Wood thought that beside the usual lesions found in these cases, the posterior root zones were also involved. Dr. John K. Mitchell presented an interesting case, the diagnosis of which was obscure. A lad, about 17 years of age, gave a history of recurring attacks of paralysis with anesthesia, involving the extremities and entire body from the neck downward. During the attacks the muscles presented the reaction

of degeneration. In certain attacks, premonitory systems frequently exhibited themselves, such as burning of the toes or other vague symptoms, and on the following morning total paralysis would come on. This paralysis would last for a day or two and gradually subside until not a trace of the disease remained. No positive diagnosis was made. Dr. Mellus of Johns Hopkins was present and read a paper on "The Motor Tracts in the Brain and Spinal Cord." The paper was based on experiments upon monkeys, in which portions of the brain had been removed from the so-called motor areas and the degeneration had been subsequently studied from the pathologic changes produced. The pathologic lesions were illustrated by lantern slides.

Southern Medical College Association.—This association met at Memphis, Tenn., December 5, prior to the meeting of the Southern Surgical and Gynecological Association, and after considerable discussion, it was decided to increase the course of study from three to four years. It is well known that the question of making the course four years instead of three has been before the association for two years, but it has been passed from time to time, in order that so radical a move might be fully discussed by all the faculties that are to be affected. Dr. Sinclair of Memphis presented the matter first at the meeting of the association in Atlanta, and since then from time to time it has been discussed frequently among each of the faculties in the association. At the meeting, only two of the thirteen colleges in the association failed to send representatives to the conference. On account of the change to the four year course, it was necessary to introduce a number of amendments to the Constitution and By-laws of the Association, but none of them was passed, because it is the rule that such amendments shall lie over for one year. This is for the purpose of giving the delegates an opportunity to present plans for whatever changes are contemplated in their respective faculties before final action is taken. The delegates present were: Drs. S. S. Crockett, of the University of Nashville; W. E. B. Davis, of the Birmingham Medical College; Christopher Thompkins, of the Virginia Medical College at Richmond; Ernest S. Lewis, of Tulane University, New Orleans; G. C. Savage, and Richard Douglas, of the Medical Department of Vanderbilt University of Nashville; T. H. Wood, of the University of Tennessee, at Nashville; Campbell of the Tennessee Medical College, at Knoxville; G. A. Ketchum, of the Alabama Medical College of Mobile, and A. G. Sinclair, of the Memphis Medical College. The University of the South was to have been represented by Dr. J. S. Cain of Nashville, but he sent a proxy in the person of Dr. Savage. The only two colleges in the association not represented were the Texas Medical College of Galveston and the Southern Medical College of Atlanta. The other absentee from the list of thirteen was the Beesemer Medical College of Beesemer, Ala., and it is no longer in existence.

Washington Medical Society.—At the regular weekly meeting of this society, held November 23, the death of Dr. C. M. Hammett was announced, and on motion, a committee of three was appointed by the president to draw suitable resolutions and report at the next weekly meeting.

Dr. D. S. LAMB presented a number of pathologic specimens, including hydrocephalus in a calf; a meningocele; an anencephalic fetus, and a specimen showing an arrest in the development in twins.

Dr. PHILIP S. ROYE read the essay of the evening entitled, "Diagnosis of Tubercular Meningitis in Children." He said the disease was generally characterized by severe headache, vomiting, constipation, under three years, drowsiness, while in older children the mind remained clear, drowsiness appearing later. Contraction of head and tenderness in cervical region, and sometimes pain in chest—taches cerebrales and cry are not pathognomonic. As a rule the temperature is low, and the

pulse rapid; the temperature curve is irregular, differing materially from that in typhoid. The history of tubercular lesions elsewhere and tubercular parentage are important factors in diagnosis.

Dr. ACKER, in discussion, referred to two cases of tubercular meningitis which occurred in his practice in the Children's Hospital of this city, and which he had reported at the last meeting of the American Pediatric Society. The first case presented a tubercular history and was rachitic and suffered from retracted head, apathy, screaming, and had irregular pulse and temperature. The second case gave a history of adenitis and keratitis, and suffered from vomiting, apathy, irregular pulse and temperature and violent headache; both these cases recovered. He quoted Dr. Jacobi as saying that he knew of one case, which he thought to be tubercular meningitis, which recovered, but had known of no others; the doubt in diagnosis being the recovery. Dr. Jacobi says the diagnosis was based: 1, on the reaction to tuberculin; 2, examination of eyes, which would present characteristic appearance of choroid coat. Post-basic meningitis gives the same symptoms and lumbar puncture is the only means of diagnosis. In tubercular meningitis the diplococcus is found. He said that Dr. Northrup gives as diagnostic in infants: persistent vomiting, apathy, irregular pulse and respiration. The Doctor said he based the diagnosis on: previous history, persistent vomiting, local spasm (head drawn to side or back) and hereditary history. Low temperature is frequent. He said all these symptoms may be present in a case and the postmortem would sometimes fail to show the presence of tubercle.

Dr. LOCHBOEHLER referred to a case in his practice in which there were no spasm or rigidity. The temperature ranged between 100 and 106, but was normal for six days. The pulse was feeble and ranged from 140 upward.

Dr. S. S. ADAMS said that diagnosis depends on the stage of disease and age of the child. It may be confounded with typhoid, and the diagnosis is impossible in the earlier stage of irritation, but easy when irritation is at its height, because the temperature is then low. In all other diseases of advanced cerebral irritation, the temperature is high.

Dr. W. W. JOHNSTON mentioned a case in which lumbar puncture afforded great relief for twenty-four hours.

NECROLOGY.

ELLIS G. ARMSTRONG, M.D., Flora, Ind., November 23.—W. H. Baker, M.D., Lynchburg, Va., November 27.—Charles M. G. Brant, M.D., Omaha, Neb., November 25.—Edwin Carson, M.D., San Diego, Cal., November 24, aged 40 years.—George Coryell, M.D., Riverside, Ill., November 28, aged 89 years.—Albert J. Phillips, M.D., Baltimore, Md., November 24, aged 43 years.—Thomas W. Simmonds, M.D., Martinsville, Va., November 21, aged 38 years.—F. H. Van Valzan, M.D., Spring Mills, Pa., November 26, aged 60 years.

JAMES ALEXANDER MOORE, M.D., Bellevue, New York City, 1883, died at his home in Helena, Mont., November 29. He was a son of the late William Moore of St. Croix, Danish West Indies.

MISCELLANY.

Carcinoma Hardened With Formalin.—Bayer urges further tests with his method of destroying the vitality of a carcinoma with injections of formalin, transforming it into a dead, removable mass.—*Die Aerztl. Praxis.*

Peculiar Stainable Bodies in Syphilitic Products.—F. Winkler announces the discovery of regular spheroidal bodies in the various lesions of syphilis (gumma, condyloma, sclerosis, lymph-gland, etc., and even in the sperm of syphilitics) never found in any other disease. They have each an eccentric light spot. Unna has been studying them with him and both agree that they are neither blastomycetes, nor hyaline products, but a peculiar, hitherto undescribed product of syphilis, of strikingly regular structure, which deserve a special place in histopathology. They stain with thiodin or toluidin blue and

decolor with formalin, or they can be stained with polychromic methylene blue and decolorized with iodized alcohol or the glycerin-ether mixture. They are more prominent if the tissue is stained with orange or eosin.—*Munich Med. Woch.*, November 8.

Perforating Ulcer of the Mouth.—Letulle of Lille has reported an instance of this rare condition in a male, aged 50 years, an alleged alcoholic subject, who presented fairly well-marked symptoms of tabes. The teeth in the left half of the lower jaw were all wanting except the central incisor, those on the right side being healthy. In the upper jaw there were only three teeth left, and apart from the persisting teeth the alveolar border was atrophied; on the right side of the upper jaw there was a cavity involving the alveolar border and the hard palate, opening like a cone into the middle meatus of the nose. The mucous membrane lining it was pale, thickened, but not ulcerated; its sensibility was much impaired. The patient was not aware of this condition, but on being questioned he said that liquid food had for five months come through the right nostril. This lesion is rare; Baudet has collected eight cases chiefly on the subject of tabes. It may be unilateral or bilateral, but always occurs in the same situation. As to the explanation of the lesion, there are two views: that of Galippe, that it is the result of alveolar pyorrhea aggravated by tabes; and that of Baudet, that it is an atrophic tabetic lesion due to the fifth nerve being affected, which begins by loss of the teeth and atrophy of the jaws, and sometimes terminates by ulceration and perforation into the antrum. The decision between these theories must be left to the future, but probably a combination of the two would be most satisfactory. At present only one case has been examined after death, and that very incompletely.—*British Medical Journal.*

Normal Urology of Childhood.—Bezy reported the results of investigations by Carron, Monfet and Thadée which establish the following standard for the urology of children past infancy. For each kilogram of the child, and in twenty-four hours, the volume of urine excreted is 30 to 38 c.c., which is one and a half to two times that of an adult; total amount of nitrogen, 30 to 33 c.c., while that of the adult is 28 c.c. The elimination of urea varies from 88 to 90 per cent.; the amount of uric acid from 9 to 10 millimeters; in the adult it is 8 millimeters. The amount of phosphoric acid is 77 millimeters, according to Thadée, and 67 according to the others. It decreases with age.—*French Cong. of Gyn. and Paediatry.*

Bronchitis.—Scheppegegrell (*N. Y. Med. Jour.*, December 3) considers abnormal nasal respiration the most frequent cause of bronchitis, and one commonly overlooked. As the most prominent conditions which interfere with or prevent normal nasal respiration, he enumerates: 1, Total absence of nasal respiration; 2, partial interference with this function; 3, lowering or loss of the normal nasal function in respiration; 4, pathologic processes in the nasal chambers by which the inspired air may be vitiated.

The Lymph.—L. Asher concludes a study of the lymph in the *Deutsche Med. Woch.* of November 17, with the statement that the lymph-glands are for the purpose of transforming the partially injurious products of metabolism originating in the work of the organs, into substances that can be utilized over again, and consequently the term "lymph" should be restricted henceforth, as the fluid entering the glands differs so essentially from the fluid that emerges. He has also experimentally established that the fluids of the serous cavities, synoviae, etc., differ from actual lymph. The morphologic indications of increased glandular activity in the vicinity of pathologic foci with increased substance destruction, seem from this standpoint merely the quantitative increase of a mechanism already at work in the organism.

Malarial Fevers on Pacific Coast.—In the *N. Y. Med. Jour.* for December 3, Perry presents results of some observations on this subject, with tables and map showing the regions in which malarial fever prevails. He finds that only the milder forms prevail, nearly always the tertian, occasionally the quartan, but rarely the aestivo-autumnal variety. In Washington they prevail only along one or two rivers in the Puget Sound Basin, the Columbia River Valley, Chehalis Valley, Yakima Valley, with an occasional case in the Columbia River Valley of the northeastern part of the State. The disease, in Oregon, is found only in the Columbia River Valley, Willamette Valley, Rogue River Valley, Umatilla Valley, with a few cases in the Columbia lowlands of Gilliam County. In California's Sacramento Valley, San Joaquin Valley, Tulare Basin and Kern Valley, with an occasional case in the Santa Clara Valley, the disease occurs.

Bilateral Resection of the Pneumogastric.—Prof. J. Pavloff has several animals on exhibition in which the vagus was cut on both sides, six to seven months ago. The only disturbance seems to be in the digestive function. There has been no pulmonary edema or pneumonia, as the animals were not allowed to get any food into the trachea or bronchi.—*Munich Med. Woch.*, November 15.

Cherry-Stone in the Eustachian Tube.—G. Trautmann reports a case of severe chronic, suppurating otitis media, with perforation, in which syringing with tepid water dislodged and expelled a cherry-stone in the Eustachian tube, the cause of the ascending suppuration. As the patient spat it out of his mouth at the third syringeful, he observed that "his head was all free again" and all the lesions healed promptly. There was nothing to indicate its presence, but all efforts to cure the otitis would have been fruitless if it had not been discovered.—*Munich Med. Woch.*, November 22.

Carbolic Acid in the Eye.—Dr. Ray of Louisville reports a medico-legal case of interest, in which a medical friend of his, practicing in central Kentucky, was concerned. Dr. A. was accused of accidentally dropping carbolic acid in the eyes of a new-born infant suffering with ophthalmia neonatorum. He was sued for damages, and Dr. Ray was asked to testify on the witness-stand. The circumstances were these: A child suffering with ophthalmia neonatorum had been ordered a solution of nitrate of silver and the nurse in attendance placed the bottle on the mantel, and along beside it she also placed a bottle of carbolic acid which had been used in disinfecting the vessels around the lying-in-chamber. The Doctor was unaware of the fact that there was any carbolic acid in the house. He came in one evening about dark to see the child, and it was apparently doing very well in about the second week of a purulent ophthalmia involving both eyes. He had the nurse take the child in her lap near the window, and he walked to the mantel and took up the bottle which was in the place he had been in the habit of finding the bottle of nitrate of silver solution, then took a medicine dropper and drew a few drops of the fluid into it and sat down to cleanse the eyes preparatory to dropping into them the solution. As usually happens, the lids were very much swollen, and in getting them open they became everted, so it was difficult for him to expose the cornea. With the lids everted in this way he dropped a drop of carbolic acid upon the exposed conjunctiva. He stated on the witness-stand, however, that he was unable to see the cornea, and that the carbolic acid only came in contact with the under surface of the lid. It ran down the side of the face over the lid and produced a little white discoloration characteristic of carbolic acid burning, and he immediately thought something was wrong. The child cried very hard, and he asked the nurse what the liquid was. She said it was the medicine he had placed upon the mantel. He went again to the mantel and found the bottle of nitrate of silver solution there untouched,

and also found that he had used carbolic acid instead. He immediately washed the eye as thoroughly as possible and applied some vaselin. The child recovered with a large central leucoma, and the doctor was sued for \$5000 damages. Asked if he ever used carbolic acid about the eye, Dr. Ray told them he did. Asked if he ever used chemically pure carbolic acid, he replied that he had done so a number of times; that he frequently applied pure carbolic acid to corneal ulcerations with a probe wrapped with absorbent cotton. Asked what he thought would be the effect of carbolic acid upon the cornea, he stated that it would be superficial; that the effect of pure carbolic acid to the healthy cornea would be to simply erode the epithelium. The Doctor was mulcted for \$350. Dr. R. does not believe that pure carbolic acid will produce a perforation of the cornea; it will destroy the epithelial layer, but that will be all. But in an eye the seat of ophthalmia neonatorum, the disease itself, in connection with the erosive effect of carbolic acid, might result in perforation of the cornea. It is well known to all that under the most approved methods of treatment a great many eyes are lost from ophthalmia neonatorum.—*American Practitioner*, October 15.

Ginseng in Korea.—Dr. Horace Allen, the United States Minister at Séoul, states that the Korean ginseng can not be regarded as inert, however correct the opinion may be of those medical writers who have reported the American root has no therapeutic power. The root is the panacea for most of the ills of the Chinese and Koreans, and has held this reputation for centuries. It is regarded by these people as a strong aphrodisiac. Quinin has been shown to be so much more efficacious in the frequent malarial fevers of these countries that ginseng has lost some of its popularity in these cases; but, wherever a tonic or a "heating medicine" is needed, ginseng continues to be resorted to, and by combination with quinin its reputation will be enhanced rather than diminished. It is supposed to owe its great popularity in China to its properties as an aphrodisiac. The district where much of the Korean root is grown is hilly or mountainous. The climate is much the same as that of the northern portions of our Central States, except that here there is a distinct rainy season, some forty inches of rain falling during July and August. It is possible that our summers may be too dry for the successful cultivation of this plant. Michigan would probably be the best place for making an attempt at the cultivation. Wild ginseng is supposed in Korea to possess almost magic properties. Such roots are usually kept for the royal family. The cultivated ginseng requires seven years to mature. It is raised in little plots of richly manured soil, well mixed with leaf mold. The beds are carefully covered by mats or other protection, raised sufficiently to allow of cultivation and of the free access of air, and care must be given to keep the plants moist and free from weeds. As there seems to be almost unlimited demand for this root in China, it might as well be produced, in all its excellence, in the United States if possible. The American and Korean ginseng roots differ in appearance; the American seems to be made up largely of fibrous roots called "beard," while the Korean root is more compact. The two are given different names by botanists. The Chinese plant is called *Aralia schinseng*, while the American is called *Aralia quinquefolia*. There is by some believed to be a difference in the effect produced by the use of these two roots. There is no market for the powdered root; the Chinaman who pays from a half-dollar to \$100 for an ounce of ginseng, wants all his money's worth. The powder might be made of any similar root of no value. Ginseng, like wine, increases in value with age. The best ginseng has been growing for 100 to 200 years. The Korean ginseng is supposed to arrive at perfection after thirty years, although it is used after six years. This is one of the reasons why ginseng is so high-priced. I take it for granted that the

American ginseng is wild, and so may be of any age, even more than a century old. The age is told by counting the rings on the center and side roots, or those parts resembling the torso and arms. Dr. Chung King-u, Imperial Medical College of Tientsin, resident surgeon of the Tung Wa Hospital at Hong-kong, the only hospital in China which is devoted to Chinese medical practice, but which is under the supervision of a Chinese physician versed in western medicine, states that in his experience he has failed to observe any definite results obtained by the use of ginseng. Its use among the Chinese is entirely empiric, and its efficacy depends upon the imagination of the patient.

Malt Combinations.—The diet of the adult human is, and must be, largely made up of carbohydrates, whose place of preparation into assimilable forms is in the small intestine. It is perhaps too much to say that a majority of the cases of so-called dyspepsia are in reality that of impaired or deficient intestinal digestion. If the food has been well masticated, and if the stomach is able to carry on its motor function and then to empty its contents into the duodenum, and if indigestion then occurs, the source of the trouble, in a majority of cases, will be found to be in the small intestine. Of all the diffusible enzymes, the special function of which is to convert starch into dextrin and later into maltose, diastase is one of the most efficient. This ferment, or one having exactly the same action, is a very essential part of the pancreatic juice, and under favorable conditions it is able to convert many thousand times its own weight of starch into dextrin. Diastase is a soluble albuminoid enzyme germinated from the gluten or cereals at the time of sprouting. Vegetable diastase, ptyalin and pancreatic diastase all act in exactly the same way, being capable of acting upon cooked starch with great rapidity. The essential factor which assures this rapidity of action is that the diastase shall be present in large quantity; when the relative proportion of the enzyme is large in comparison with the amount of starch the transformation goes on rapidly and the action continues for a long time. Since a large part of the digestive work is done in the small intestine, and since the ferment called pancreatic diastase or amylase has been assigned to it the digestion of all the starchy food which is contained in the diet, since the action of pancreatic diastase and of vegetable or malt diastase is so identic as to be incapable of distinction, it is no wonder that the preparations of malt diastase have come into general use in the treatment of all the varied forms of indigestion. The preparation of vegetable diastase known as "maltzyme" has come into general use among physicians, and the fact that it has received the patronage and endorsement of medical men all over the country, is proof positive that the preparation is strong in diastatic power. Maltzyme is not alone efficient in digestive power, but it is also pleasing and palatable, and furnishes an ideal vehicle for the administration of the other remedies with which it has been combined—cod-liver oil, cascara and the hypophosphites. Maltzyme preparations are nutritive as well as highly diastatic, because they contain predigested carbohydrates and nitrogenous material combined with the phosphates of the grain. It is highly important that all who practice medicine should recognize the value of the best preparations of malt, for it is often necessary, while giving treatment to separate organs, that the physician should give special attention to the digestive organs and processes, or else he will find his results unsatisfactory.—*Jour. of Med. and Sci.*, September.

A Quinquennial Census Necessary.—Dr. E. W. Hope of Liverpool objects to the official estimate of population in his city, as based upon the regular decennial census. He has been a careful student of the subject for many years, and it is his belief that a material underestimation of his city's growth has resulted from "the rule of thumb" measures and methods that

obtain in official circles. He says that during recent years reasons have been growing stronger for calling into question the correctness of the results of the method adopted by the registrar-general for estimating the population of the city. The method, it will be remembered, is based upon the assumption that the rate of change (increase or decrease) in the various districts of the city which took place year by year during the intercensal period ending in 1801 has continued since. The registrar-general estimates that the population has increased from 629,443 in 1801 to 633,645 in 1898, i.e., the total population of greater Liverpool has increased by 600 every year, making a total increase during the seven years of 5200. The reasons for believing that this estimate is very much below what the population actually is may be summarized in the following manner: The natural increase of the population, viz., the increase in the number of births over deaths since the census of 1891, exceeds 40,000. The increase in the number of registered voters since the last census exceeds 26,000. The increase in the number of houses built over those which have been demolished since the last census is close upon 3500. The increase in the number of inhabited houses since the last census was found, by police inquiry early in this year, to be upward of 14,400; making a liberal deduction of 5 per cent. for a possible margin of error, leaves an increase of 13,620. Each of these facts suggests strongly that the actual increase has been greater than the estimated increase. Clearly, what is wanted is a more frequent census for the whole country, certainly not less frequently than every five years. It is singular that the registrar-general is satisfied week after week and year after year to publish, under the imprimatur of his office, figures which everyone conversant with the subject must hesitate to accept as correct. No word of explanation, no word of warning, no comment is issued with these returns; cities and districts are strung together for comparison, with egregiously misleading results, and with consequences which tend to cripple and retard sanitation. No doubt a quinquennial census would go far to correct these mistakes, and tend not only to prevent the waste of time involved by the compilation and issue of fictitious returns, but also to put an end to the mischief which such returns give rise to. But, pending such a census, it is unsatisfactory to find that the registrar-general regards the subject as of so little importance as to decline to discuss it, preferring to leave the matter for his successor to deal with. The decennial census was inaugurated one hundred years ago, and the benefits afforded by it now require to be supplemented by a quinquennial one. At the meeting of the Section of State Medicine of the British Medical Association in Edinburgh, July 27, 1898, a resolution was unanimously passed to the effect that it was absolutely essential that a quinquennial census of the whole country should be taken in order to ensure accuracy in statistics relating to the public health. In Germany a five-year census is taken, and in Japan the register of the population of each sub-district is corrected annually by the addition of infants born or of persons domiciled in the district, and by the removal of persons dying or leaving the district.—*Public Health*, October.

The Teaching of Anatomy.—The teaching of anatomy at Columbia University has reached the differentiation stage of progress. A new curriculum has been adopted, in such a manner that the topics will be distributed in a two-year course in human anatomy, and the students may be distinguished as being either of the elementary or the advanced classes. Dr. G. S. Huntington of the College of Physicians and Surgeons, who has labored early and late to bring about this improvement in his branch, has published his views of the probable results of the new teaching, in *Bulletin XX*, of the Columbia University. He says that the new plan has enabled his school to solve a part of the problems of the intelligent education of his pupils in as nearly a satisfactory manner as seems now to be possible.

The first-year student does not attend any lectures in anatomy. During this year the instruction consists in practical demonstrations to small sections of the class, dealing with the entire anatomy of the extremities and with the bones, joints, muscles and blood-vessels of the head and neck, including also part of the peripheral nervous system of this region. In direct connection with the demonstrations, extensive practical work in the dissecting-room is required. The first-year student also attends a series of demonstrations constituting the preliminary visceral course, designed to afford that general information regarding the body cavities and their contents which is requisite to the correct appreciation of the concurrent instruction offered by the departments of physiology and histology. In the second year the laboratory work continuing, the student attends demonstrations to sections of the class in the anatomy of the central nervous system, organs of special sense and cranial nerves. The entire second-year class attends three lectures a week on the anatomy of the body cavities and viscera. The preparations illustrating these lectures are, in the afternoon of the lecture-days, demonstrated again separately to sections of the class, enabling each student to study and inspect the same closely. In this way an opportunity is given to make the anatomic lecture what it should strive to be, not an attempt to teach anatomy at long range to several hundred men at once, but an occasion for presenting the broad morphologic principles upon which the animal organs, apparatus and symptoms are constructed. Here the significance and importance of the structural peculiarities of the man can be accentuated, illustrated, and explained in all their bearings by contrast with the corresponding structures of the lower vertebrates. It is quite evident that the institution must command the requisite material for illustration in order to carry out a liberal plan of instruction in general morphology. The progress of the last eight years in this respect has been gratifying. The morphologic museum began its development in 1890 in one of the small rooms in the cellar of the south wing. Columbia today possesses an equipment which, while it still falls short of the ultimate design, yet is unequalled in the beauty and clearness of the preparations, and in the complete character of the series most extensively used in the courses of instruction. The first and second floors of the new anatomic building are designed to be the permanent home of the museum, and provide ample floor and gallery space. It is the confident hope of the department that here the future growth of the collection will be as rapid and healthy as it has been in the past under less favorable surroundings. Unfortunately, however, it was found necessary at the time the anatomic building was erected to leave out the equipment, and the department is today in urgent need of cases for the two floors. The old cases inherited from the pathologic museum are overcrowded and have to be used merely for storage. The museum loses one of its most important educational features in not being accessible for purposes of serious study in present condition. It is not possible to carry out the systematic serial exhibition which is the fundamental principle in the application of the collection of the student.

Surgical Scenes in Asia Minor.—Dr. William S. Dodd, a medical missionary at Cesarea, Asia Minor, writes of his surgical experiences following a little local war or revolt. He says: "When I have read the surgical reports from the army at Santiago, and learned that out of nearly thirteen hundred wounded, only sixty-eight died, and hardly one of these from wound infection, I could not but contrast such a condition with the results of a recent incident in this land. The preparations made for the immediate application of antiseptic dressings to the wounds by the wounded themselves or by their comrades, together with the general intelligence of the men who make such preparations effective, is so utterly different from any-

thing that could be thought of in this land on the part either of the people or the authorities as to make one realize the blessings of civilization and Christianity. A week after the fight there came to me a messenger from Oozoonloo, requesting me to see the wounded. Not a physician or surgeon had been sent by the Government to look after the suffering. In this country there are no physicians except in the cities, so that the region for a distance of ninety miles is a blank, as far as medical service is concerned. Before I could go I must have the permission of the Government: official word must be sent back and forth before this could be secured, inasmuch as Oozoonloo is not under our own governor: and so it was eleven days after the battle when I reached there. I found then that a Turkish physician had reached there shortly before me, but he knew nothing of surgery, had no antiseptics with him, and the wounds were, of course, all in a horribly septic condition. Many of them had had no change of dressing for several days, and these, too, compound and comminuted fractures of large bones. The village dressing in such cases oftentimes consists of fresh manure applied with the idea of reducing inflammation. In the case of the father of a poor family of six children, on whose account more than of any other one person I had been begged to come, lockjaw had already set in, and he died soon after. The Turkish physician had no idea of drainage for these deep discharging wounds, having plugged them all with pieces of twisted wicking, the universal method of "drainage" in this country. I used up three yards of drainage tubing in dressing seventeen cases. I left a supply of antiseptics and of directions with the man who does the local "doctoring" of the place, and so came away feeling that my visit would not be wholly in vain. The whole incident is pre-eminently Turkish. The change of the seat of government for the sake of self-interest of officials, the element of bribery in the case, the foolish opposition of the people, their persuasion that force would not be used against them, the encouragement to this belief from the long dallying of the authorities, the final outburst ten times more bloody than was needed, the neglect of the suffering and carelessness for their welfare, and the ignorance of the official government physician who came more to make a report on the wounds of the dead than to care for the living—all these are just what one would expect in Turkey.—*The Evangelist.*

Medical Inspector for the Army.—Col. Charles R. Greenleaf, assistant surgeon-general, U. S. A., has been assigned to duty as medical inspector. The scope of his duties has been defined in a letter addressed to him, Dec. 3, 1898, by the Surgeon-General, as follows: In the discharge of your duties as medical inspector of the army you are expected to report to me upon the sanitary condition and wants of troops in the field, at military posts and in general hospitals, and as regards the skill, efficiency and conduct of officers, enlisted men and civilian employes connected with the medical department. You will see that existing orders and regulations relating to the medical department are complied with, and that all prescribed reports and returns are promptly made and forwarded when due. You will examine into the quality, quantity and condition of medical and hospital supplies, reporting any failure upon the part of responsible medical officers to make proper requisitions, and any deficiencies found due to failure on the part of supply officers to promptly fill approved requisitions. You will ascertain what diseases are most prevalent in the camps visited by you, and will inquire into the cause of such prevalence and the steps which have been taken for the prevention or arrest of any infectious diseases which may exist, indicating verbally or in writing to the responsible medical officers such additional measures or precautions as may be requisite. When sanitary reforms requiring the sanction and co-operation of military authorities are urgently demanded, you will report at once, in

writing, to the officer commanding the military department, corps, division or camp, calling his attention to the facts, and recommending such measures as you consider necessary for the relief of insanitary conditions existing. A duplicate of such report should be forwarded to the Surgeon-General of the army. You will ascertain whether medical supplies are properly used and with due regard to economy; whether any additional articles not now included in our supply-tables are necessary for the treatment of the sick; whether the equipment of regimental hospital is such as is contemplated by recent orders; whether cases of infectious diseases or of soldiers seriously ill are improperly retained in regimental hospitals; whether division hospital are fully equipped as regards supplies, medical officers and attendants to properly care for the sick of the command to which they belong; and whether contract surgeons have been examined as prescribed by recent orders. You will give especial attention to diet kitchens, and see that they are equipped for providing the sick with suitable light diet. You will ascertain whether a proper use is made of the fund provided for the purchase of suitable articles of diet for the sick, as prescribed in General Orders No. 116, and whether the commissary department has on hand for sale such articles as are necessary. You will also inquire as to the sufficiency of tents, ambulances, and other articles furnished by the quartermaster's department. You will report any abuses or deficiencies existing to the commanding general of the department, corps, division, camp or military post, sending a duplicate of this report to the Surgeon-General of the army. You will also report upon the professional competence, attention to duty, and general qualifications of medical officers, calling the attention of the Surgeon-General to those who deserve especial commendation, and also to those who are considered incompetent, or for any reason undesirable members of the medical department. You should give especial attention to the efficiency of the hospital corps, reporting whether proper discipline is maintained and proper instruction given in all that pertains to the duties of enlisted men of that corps.

Not Synonymous.—According to a judge of the court of the State of Rhode Island and Providence Plantations, medicine, in the popular sense, is a remedial substance. The practice of medicine, as ordinarily or popularly understood, has relation to the art of preventing, curing or alleviating disease or pain. It rests largely in the sciences of anatomy, physiology and hygiene. It requires a knowledge of disease, its origin, its anatomic and physiologic features, and its causative relations; and further, it requires a knowledge of drugs, their preparation and action. Popularly, it consists in the discovery of the cause and nature of disease and the administration of remedies or the prescribing of treatment therefor. This all assumes importance when the supreme court of Rhode Island says, in the case of *State vs. Mylod*, July 18, 1898, that, in the construction of penal statutes, a well-established rule is that words and phrases must be taken in their ordinary acceptance and popular meaning, unless a contrary intent appears, and that the words "practice of medicine" must be taken in this, their ordinary or popular meaning, in determining whether a statute regulating same is violated by certain acts of a Christian scientist, for example. Its conclusion is that prayer for those suffering from disease, or words of encouragement, or the teaching that disease will disappear and physical perfection be attained as a result of prayer, or that humanity will be brought into harmony with God by right thinking and a fixed determination to look on the bright side of life, does not constitute the practice of medicine in the popular sense nor, therefore, violate the statute referred to. And the court does not think that because the statute applies not only to those who actually practice, but also to those who announce in any way a readiness to practice, that the legislature intended to give a broader

than the generally accepted meaning to the words "practice of medicine." The most that it thinks can be claimed for this feature of the statute is that it operates to broaden the offense created by the statute so that the attempt or the announcement of a readiness to practice medicine becomes equivalent to the actual practice. Furthermore, a recognition by the statute of the existence among medical men of differences regarding the treatment of disease, while certain diseases are treated by the "regular school" without the use of drugs, the court maintains, does not broaden the meaning of the words "practice of medicine" to include the practice of that which, in the popular sense, is not a practice of medicine. To give to the words "practice of medicine" the construction claimed for them, it also suggests, would lead to unintended results, because, if the practice of Christian Science is the practice of medicine, Christian Science is a school or system of medicine, and is entitled to recognition by the State board of health to the same extent as other schools or systems of medicine, as, under the statute under consideration, the board has no arbitrary power, and can only determine whether the applicant possesses the statutory qualification to practice in accordance with the recognized theories of a particular school or system. To protect the public, not from theories, but from the acts of incompetent persons, the court goes on to say, the legislature has prescribed the qualifications of those who may be entitled to perform the important duties of medical practitioners. The statute is not for the purpose of compelling persons suffering from disease to resort to remedies, but is designed to secure to those desiring remedies competent physicians to prepare and administer them. Nor does it, in terms, prohibit the use of the word "doctor" by any person, whatever his business or profession may be. The assumption of that title by a Christian scientist is not unlawful, and the use of the word is entirely immaterial in any case, unless under such conditions or circumstances, or in such connection, that it may serve as an announcement or indication of a readiness to engage in the practice of medicine or surgery.

Necessity of Intestinal Bacteria.—Schottelius recently raised some chickens from the egg in absolutely aseptic conditions. with the result that the fowls did not thrive like the control-chickens, but gradually dwindled away and died by the seventeenth day.—*Munich Med. Woch.*, No. 36.

Physicians' Strike.—The difficulties between the profession and the "sickness insurance associations" in Germany culminated recently in a definite "strike" on the part of the medical men in two German cities. The strike at Barmen resulted in favor of the physicians, as a satisfactory compromise was effected, but at Remscheid the organization won the day, bringing in outsiders to fill the vacancy, although with the result of the founding of a new association with the former medical attendants. These associations to provide medical attendance in case of illness, are for the benefit of the laboring classes, and are mostly managed by working men or small trades-people, who assert their mastery over the physicians who contract to attend to their sick, by appointing and dismissing them at pleasure, a system which leads to many abuses. It has been abolished in some places where the association makes a contract with some local medical society, any members of which can be summoned to their sick at contract rates.

Red Ant Pest at Albany.—Taken individually, the small red ant (*Monomorium pharannis*) is not difficult of extinction. A well-planted foot will terminate the existence of the hardiest specimen. Taken en masse, however, he prospers exceedingly, even under adverse conditions, and his multiplication is fairly logarithmic for speed. Pouring boiling water, benzine or kerosene emulsion upon his domicile, if it can be found, tends to discourage him. The difficulty is to track him to his lair. Old and rotting woodwork is a favorite abode of his, and the old-

fashioned wooden sidewalk forms a roof of easy exit for populous ant cities. It is unlikely that the Albany correspondent will be troubled further this year by the small red pests. If he will start in early next summer and trail home the first red ant he sees about the house, he will probably be able, by a liberal use of the hot water boiler, to free his own immediate vicinity from the industrious and pervasive insects.—*New York Sun*.

Gleanings.—The *Bulletin de la Soc. de Pharmacie* states that bismuth salicylate should be rejected on account of its uncertainty and impurities, and the subnitrate used or, better still, the "cream of bismuth," the hydrate of bismuth oxid. . . . Orthoform is warmly recommended for cracked nipples. Besides its analgesic action it is astringent and antiseptic, healing the cracks in a few days. . . . Nitrate of silver crayons are found more effective than the solution, for buboes, panaris, etc. A crayon 2 to 4 mm. in length, inserted and left, will rapidly cure the lesion without too much caustic action (*Semaine Méd.*, November 16). . . . Netter ascribes to the sterilization a case of infantile scrobutus in a child fed exclusively with home Soxhlet sterilized milk from a well-directed dairy. In 103 observations there were only 11 in which similar conditions prevailed. In 29, the milk was bought ready sterilized. The rest used various preparations (*Bull. des Hôp.*, November 10). . . . Birth of twins with eleven days interval between them (*Lyons Méd.*). . . . Wolfe reports the case of a healthy woman who never menstruated, but when 45 years of age was much frightened by an insane girl, commenced to menstruate the same day, and eight months later conceived and bore a healthy child (*Lancet*, August). . . . Schultze adds another to the eight cases on record of echinococcus ovarii; not diagnosed before operating; patient recovered a year later. . . . Non-closure of the foramen ovale forming almost entire absence of septum in patient of 42 years, and in another of 62 (*Deutsche Med. Woch.*, November 17). . . . Lechner describes the case of a student who can make one eye go through the motions of abduction and adduction, while the other is fastened on a fixed spot, without varying the accommodation. It confirms Herring's law in regard to the associated innervation of the ocular muscles (*Graefe's Archiv.*, No. 3). . . . Professor Hayem's new clinic at the Saint-Antoine is arranged so that it can be darkened at a moment's notice, for radiographic work, projections of microscopic preparations, etc. . . . Two cases of tubo-abdominal wall fistulas are reported, through which menstruation occurred during the period, showing the bloody discharge in the tubes as in the uterus (*Cbl. f. Gyn.*, No. 45). . . . Rose recommends a wedge-shaped excision of the tubes from the uterus to protect against subsequent gonorrheal infection of the peritoneum, or to insure sterility. . . . Case of fatal intoxication from injection of gray oil (*Berlin klin. Woch.*, No. 46). . . . Case of noma after scarlet fever, with congenital syphilis, cured with potassium iodid (*Deutsche Med. Woch.*, 46). . . . Three cases of aneurysm of the mitral valve, observed by Drasche. Peculiar musical sounds noted. Small chronic aneurysms of this kind sometimes heal spontaneously (*Vienna klin. Woch.*, 45). . . . Case of myxedema in woman of 47 years, progressing for years, completely cured with thyroid tablets. . . . According to the *Munich Med. Woch.* of November 22, Finsen's "Light Institute" at Copenhagen (vide JOURNAL, page 303) is richly endowed, and the daughters of the best families volunteer their services as attendants. His treatment of lupus with concentrated electric light is proving very successful. . . . Unfavorable influence of kidney troubles on the course of an infective disease is confirmed anew by a fatal case of measles in a patient with nephritis (*Vienna klin. Rund.*, 47). . . . Naughehauer reports a case of extra-uterine pregnancy nearly at term; living

child extracted through the abdomen; mother recovered; placenta implanted in the cavum vesico-uterine (*Vienna klin. Rund.*, 47). . . . Sudnik has found the "high frequency" current very valuable in reducing an intracaracoid luxation of the shoulder. Besides its anesthetic effect it acts directly upon traumatic contractions (*Journal d'Hygiene*, Nov. 17).

Old Plantation Malady.—Doctor: Your wife must have chicken broth three times a day, and you must give her a spoonful of this medicine every hour during the night. Mr. Jackson (dubiously): Wa-al, doctah, I doan' see how yo' specks me toe pervide her wif de chicken broff and gib her dat medicine at de same time.—*Factotum*.

Washington.

HEALTH OF THE DISTRICT.—The report of Health Officer Woodward, for the week ended December 3, shows the total number of deaths to have been 117, of which 69 were white and 48 colored. The principal causes of death were: consumption, diphtheria, nervous diseases, heart diseases, diseases of the kidney, pneumonia, scarlet fever and typhoid fever. At the close of the week there were 123 cases each of diphtheria and scarlet fever under treatment.

NEW MUNICIPAL HOSPITAL.—Senator McMillan has introduced a bill in the Senate which provides for the building of a new municipal hospital, in which shall be treated the patients now cared for in the Columbia, Freedman and Almshouse Hospitals. The bill directs the trustees of the Columbia Hospital to sell that property and hand the proceeds into the United States Treasury Department. It further provides for an appropriation of \$200,000 for the purchase of a site for the proposed hospital, and a further sum of \$50,000 to begin the erection of buildings, which may, when completed, cost \$200,000.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.—The monthly meeting of the attending staff was held December 3, to receive the report for the month of November, which was as follows: Number of new cases, 566; number of ward patients, 81; number of emergency cases, 362; number of redressings, 188; number of prescriptions, 2989; number of deaths, 7; number of postmortems, 4. Dr. Mohart, assistant resident physician, who has been seriously ill for the past two weeks, is now convalescing and will shortly resume his duties. Dr. James R. Church, the medical hero of the Rough Riders, and formerly a resident physician of the hospital, has successfully passed the examination and been admitted as a surgeon of the regular army. Dr. Church is a graduate of the Columbian University.

Louisville.

A RETROSPECT.—Dr. T. B. Greenley of Meadow Lawn, Ky., read a very interesting paper before the Filson Club on the 5th inst., entitled, "The Doctors of Long Ago," which was a delightful reminiscence of the physicians of Louisville during a period between 1844 and 1846, during which time Dr. Greenley was a student of the University of Louisville Medical Department, and subsequent years. The oldest physician in Louisville at that time he said was Dr. Hall, who in 1797 was elected assessor of the town, which then consisted of not more than 500 inhabitants. Another of the pioneer physicians mentioned was Jas. C. Johnson, the first white male child born in Louisville after its settlement on the banks of the Ohio. Dr. Greenley is still in active practice, though more than 80 years of age, and has long been an active medical society worker, last year attending the meeting of the Kentucky State Medical Society, three local and county medical meetings, the AMERICAN MEDICAL ASSOCIATION in Denver, and the meeting of the International Association of Railway Surgeons at Montreal, he being the local surgeon at Meadow Lawn to the Illinois Central R. R.

APPROPRIATION.—Among the appropriations mentioned in the dispatches from Washington is one of \$8,500 for the Marine

Hospital at Louisville. For the five internal revenue districts of Kentucky, \$151,500 is appropriated.

OSTEOPATHY.—In the case of G. N. Murphy against the State Board of Health, the injunction granted by Judge Settle preventing the Board from molesting the plaintiff in the practice of his profession, has been made perpetual. The State Board of Health has appealed the case, and as it is of such vital importance to the Board, the case has been set for an early hearing. This is the case in which the Board sought to revoke the license of Dr. Murphy for practicing osteopathy.

London.

CALCULI AND CANCER.—An interesting discussion developed in the Pathological Society, November 18, over the specimens of primary carcinoma of the gall-bladder, one shown by Prof. Bradford without a calculus present, and one by Dr. Hunter with a calculus firmly grasped by the growth. Dr. Hunter was of the opinion that the presence of gall-stones in cancer was simply a coincidence, like a carious tooth in epithelioma of the tongue or lip. Dr. Voelker took the same view, although they certainly were much more commonly present in carcinomatous gall-bladders than in normal ones, the proportion being about 70 and 30 per cent. respectively. This might easily be accounted for by blocking and derangement of secretions. Several others spoke in the same strain. The secretary, Dr. Rolleston, believed that while much of the coexistence of the two conditions might be ascribed to mere coincidence, it could not all be so explained. He cited the recent researches of Zeigler, who found calculi present in 90 per cent. in a large number of cases of primary carcinoma he had collected. To check this result, he cited some sixteen cases of secondary invasion of the gall-bladder, and found stones present in only 20 per cent. Acting upon this suggestion Rolleston had searched his own hospital case reports and found five cases of primary cancer, in four of which stones were present, and six cases of secondary invasion in only two of which were calculi found. He, therefore, agreed with Zeigler that some important relation actually existed between gall-stones and primary carcinoma. The president, Dr. Payne, thought that cancer of the entire alimentary tract was rapidly increasing in frequency, and the gall-bladder was no exception. He regarded the relation between it and calculi as extremely uncertain.

HARBEN LECTURE.—In the last Harben lecture upon "Tuberculosis," Sir Richard Thorne discussed the problem of compulsory notification of phthisis, and, after a careful survey of the field, pronounced definitely against it. He regards the case of tuberculosis as far from parallel with that of scarlet fever or diphtheria, and thinks that at present legal interference will do more harm than good, preferring to rely upon educating popular opinion. The experience of New York City, he regards as conclusive, inasmuch as the enforcement was extremely partial and only practically among the tenement classes, and secondly, because the marked diminution in the death-rate attributed to it was already in progress before the measure was enforced.

THE GREEN OYSTER.—Professor Herdman, as chairman of the special commission upon the oyster industry, has just made an important report. The commission finds that the green color liable to occur in oysters is due to two causes: one, as in the celebrated "green oysters" at Marene on the French coast, so highly prized by epicures, and the bivalves from certain English river-mouths, harmless, and due probably to swarms of small vegetable organisms; the other, as in some American oysters and those from Falmouth, and possibly from Colchester, is caused by an excessive deposit of copper and iron in the tissues, and is probably pathologic. The copper is deposited from the blood by the leucocytes, both in the tissues and upon the surface of the body, in the form of a basic carbonate. The interesting feature of this change is that as cop-

per plays much the same rôle in the blood of molluscs, as iron does in that of mammals, we may here have a deposit of blood salts, such as occurs in chlorosis and pernicious anemia—our human "green sickness;" indeed, Herdman described the process as a "leucocytosis." But, unfortunately, the oyster is not satisfied with the association of harmless micro-organisms. The commission reported the finding of large numbers of bacilli of the colon group, some of which gave reactions suggestive of bacillus typhus in the gill-cavities and stomach of many samples of oysters. None of these oysters, however, had been taken from pure sea-water, but as the bivalve has a distinct affinity for sewage bacteria, and a saying of the fisherman is "the muddier the water, the fatter the oyster," so that they are brought farther and farther up the estuary as the time of their marketing approaches, they recommend that active measures be taken to inspect all oyster-beds frequently with reference to their possible contamination by sewage. There seems a decided probability that the oyster actually collects the bacteria from the water, as its food consists chiefly of vegetable micro-organisms, and it fattens rapidly in water containing small amounts of sewage. It is not injured by the pathogenic germs and probably would digest them along with the others. What we suffer for is our rudeness in interrupting the oyster during digestion.

MEDICAL SOCIETY OF LONDON.—At the last meeting, the president, Mr. Edward Owen, reported a successful gastro-enterostomy for pyloric cancer, with the use of the Murphy button. The patient was failing rapidly in strength, but since the operation in July last, had gained twenty pounds and was nearly free from pain. Mr. Battle presented a case of total disappearance of a large sarcoma at the neck and superior mediastinum, under the use of Coley's fluid. The President objected to the case going into the Transactions as an instance of cure by this method, as he thought the real nature of the growth uncertain. Mr. Mansell Moullin congratulated Mr. Battle upon reporting the *first authentic case* of cure by Coley's fluid (italics ours) in this country, which in view of his championship of the method and its numerous trials, was rather a surprising statement. Mr. Waterhouse declared himself very skeptical as to the value of the method and the reliability of some of the reports made upon it. He himself had tried it in five cases with no result whatever, except the death of two patients by hyperpyrexia. The impression seems to be general that no one else can get such results as Coley reports.

CHANGE OF ADDRESS.

Burns, T. M., from 925 to 841 So. Water Street, Denver, Colo.
Bradford, H. W., from Jamaica Plain, Mass., to Wolfboro, N. H.
Beach, S. C., from McCook to Ravenna, Neb.
Brown, L. Roy, from Heron to St. Paul Park, Minn.
Craig, J., from White Sulphur Springs to Columbus, Mont.
Clark, J. A. M., from Detroit to Cascade, Mich.
Cutter, J. B., from Colonial Hotel to Presidio, San Francisco, Cal.
Durbine, L. T., from 2430 Stout to 1763 Clarkson, Denver, Colo.
Dougherty, P., from Los Angeles to 80 So. Madison Ave., Pasadena, Cal.

ADDRESSES.

EMPHYEMA IN CAMP GEORGE H. THOMAS.

Annual Address delivered before the Pittsburg Academy of
Medicine, Dec. 2, 1898.

BY N. SENN, M.D., PH.D., LL.D.

Professor of Surgery in Rush Medical College, in Affiliation with the
University of Chicago; Late Lieutenant-Colonel U. S. V., Chief of
the Operating Staff with the Army in the Field.
CHICAGO.

The short, decisive campaign with Spain just ended was characterized, from a medical standpoint, by the smallness of the number of those killed in the field, the prevalence of disease and the large number of deaths from this source. The brilliant victories on land and sea which forced Spain to sue for peace have cost us so far over three thousand lives—less than three hundred from the effects of bullets and over two thousand nine hundred from disease. The number of deaths from disease will be increased materially, as the different military hospitals at home and abroad still contain a large number of our sick, many of whom will succumb to the diseases contracted during the campaign. Even in case the hostilities are not renewed, it is impossible to predict the total loss of life at the present time, to say nothing of the thousands who will never recover the health they brought into the service. The unusual amount of sickness which prevailed among our troops, in our home camps and at the seat of war, can be attributed to various causes. The call to arms came at a time of the year when bronchial affections, pneumonia, pleuritis and rheumatism are prevalent. In the State camp of the Illinois troops cerebro-spinal meningitis made its appearance during the first days of their encampment. Typhoid fever had its origin in our State camps and followed our army to the National camps and to the seat of war in Cuba and Porto Rico. The accumulation of large armies and the prolonged encampments in localities which lacked a system of sewerage, could not fail in promoting the local spread of infectious disease. The invasion of Cuba occurred during the rainy season, which had a deleterious effect on the health of the unacclimated troops, rendering them more susceptible to the effects of the semitropical climate and the prevailing diseases. The transportation facilities for the unloading of the transports were utterly defective in furnishing the invading army at the proper time with the necessary supplies. The clothing of our troops was not adapted for the Cuban climate. And, lastly, the necessary precautions to protect the troops against yellow fever, which is always found on the Cuban coast, where the landing was effected, were not carried into effect. The commanding general had been fully advised by the Chief Surgeon of the Army in the Field, but the instructions were ignored in the haste and tumult of the brief campaign. A lack of a good knowledge of sanitation

on the part of many of the medical officers, and especially the inadequate policing of the camps, had their influence in promoting the local spread of disease. Amebic dysentery and malaria, the two tropical diseases to which our troops were exposed in the southern camps and in Cuba and Porto Rico, figured largely in the sick and mortality reports. The prevention of these diseases was beyond the control of the medical department. The ordinary camp diarrhea, from which almost every participant of the war suffered to a greater or lesser extent, I am satisfied, did much to increase the receptivity of our soldiers to typhoid fever infection.

Another matter of the greatest importance concerning the health of our troops was the regulation government ration. The food selected and furnished for the army in Cuba and Porto Rico was the same as that which had been used in the North. Every one who served at the front for any length of time must be convinced that the emaciated, starved condition of our soldiers who returned from Cuba, and who escaped disease, was largely due to the nature of the food upon which they had to subsist. The purchase of food at the seat of war was out of question. Investigation will undoubtedly prove that many of the canned meats did not contain the amount of nutriment claimed for them. Fresh meat and black bread furnished the continental armies are not only more palatable, but also more nutritious than the canned meats and hard-tack furnished our army. A careful inquiry into the kind of food our occupation armies should be furnished, is one of the most important duties of those who are in charge of the commissary department. Another subject of special importance is the special diet for the sick.

It is to be hoped that the medical department will be consulted concerning these matters, and that the recommendations made will receive the well-merited attention of the military authorities. During my service, I met one of our soldiers who served under General Gordon in his advance on Khartoum, who informed me that during that campaign the British troops were supplied, on the whole, with much better food than was the case in Cuba. England has benefited by long experience how to conduct a campaign in a tropical climate; we are novices in this kind of warfare, but have learned enough during the last six months to enable us to take better care of our troops, should we again be called upon to conduct a war beyond the limits of our country.

I have deemed it appropriate and advisable, in accepting your kind invitation to deliver the address at this annual meeting, to discuss briefly and from the most practical standpoint, a surgical affection which I had an opportunity to study in a most satisfactory manner during my service at Chickamauga. It is my purpose to occupy my allotted time by relating my experience with empyema in Camp George.

H. Thomas. I was on duty as chief surgeon in that camp for nearly four weeks during the months of May and June. During that time the camp was occupied by nearly 40,000 men, representing nearly all of the States east of the Rocky Mountains. With the exception of one company of cavalry on guard duty, the army was composed entirely of volunteers. The days were hot, the nights cool; the midday temperature frequently reached 98 to 100 degrees F. The drouth which prevailed at that time rendered the roads dusty, the clouds of dust being only settled occasionally by showers of short duration. Camp diarrhea, dysentery, cerebro-spinal meningitis, pneumonia and typhoid fever were then the principal diseases we had to contend with.

It is one of the complications of pneumonia—empyema—as observed in Camp George H. Thomas, that I desire to discuss this evening. Empyema represents the pathologic product of suppurative pleuritis. Suppurative pleuritis is always the result of a pyogenic infection of the pleura sufficient in virulence to give rise to pus formation. In the absence of traumatic causes it appears clinically and pathologically either as an isolated inflammation of the pleura or as a more or less remote complication of pneumonia. Bacteriologically speaking, suppurative pleuritis can only result from the presence in and the specific action upon, the tissues of the pleura of pyogenic microbes in sufficient number and virulence to give rise to a suppurative inflammation.

Non-traumatic, suppurative pleuritis is a comparatively rare, isolated affection; in the great majority of cases it presents itself as a complication of pneumonia. Recent investigations tend to prove that the essential cause of pneumonia is either Fränkel's pneumococcus, Friedlander's bacillus of pneumonia (diplo-bacillus) or the streptococcus pyogenes. Streptococcus pneumonia, occurring either as a primary or secondary affection, is characterized clinically by the gravity of the disease and pathologically by the tendency to pus formation. The microbes of pneumonia discovered and described by Fränkel and Friedlander are the bacteriologic agents usually found in the inflamed tissues in croupous pneumonia. Both these microbes possess feeble intrinsic pyogenic properties, and when, during the pneumonic process, abscess formation or suppurative pleuritis sets in, the complication occurs usually as the result of a secondary or mixed infection with pus microbes. Croupous pneumonia is a self-limited disease, and when febrile symptoms persist after a sufficient time has elapsed for the disease to complete its typic cycle, it is usually an indication that mixed infection has occurred, and in this event it becomes the urgent duty of the attending physician to look for, locate and determine, if possible, the nature of the complication to enable him to institute timely, appropriate therapeutic measures.

In suppurative pleuritis complicating pneumonia, the inflamed lung tissue is seldom involved in the suppurative process. Resolution may proceed in a satisfactory manner at the time and after the suppurative pleuritis has set in, a fact which would tend to prove that the parenchyma of the lung is more resistant to the action of pyogenic microbes than the tissues of the pleura, or that these microbes find their way more readily to the pleura than into the pneumonic focus after secondary infection has occurred. The complicating secondary pleuritis manifests itself

usually about the time the crisis is expected or a few days later. It is evident that suppurative complications in cases of pneumonia would be likely to appear in cases in which the tissues are rendered susceptible to the action of pus microbes and under circumstances which would supply the bacteria for the secondary, mixed infection.

Both these conditions were present and operative in Camp George H. Thomas. The health of many of the men encamped at Chickamauga was impaired soon after reaching camp by the sudden climatic changes, change of food, malaria and camp diarrhea. Nearly all cases of pneumonia were characterized by the gravity of the symptoms and a tardiness with which resolution occurred. Camp Thomas was located on the government reservation ten miles south of Chattanooga. The ground is undulating and in part well wooded. Numerous clearings and open spaces furnished excellent facilities for the drilling and maneuvering of the troops. The National Park is traversed by a sluggish stream, the Chickamauga. Three regiments of cavalry and a number of batteries were in camp during the month of June, the time the five cases of pneumonia complicated by empyema came under my observation. The ground is intersected by numerous roads which during the season of drouth which prevailed at that time, became covered with inches of fine dust, which by driving of innumerable vehicles of all kinds, the marching of troops, the passage of cavalry and artillery would rise in dense clouds and by sudden gusts of wind would often cover the entire camp. This dust was contaminated by pathogenic microbes of all kinds, which could not fail in finding their way into the air-passages of the occupants of the camp. The dust was most abundant near the roads on which there was the most travel, that is, near headquarters.

It was not strange that most of the cases of pneumonia originated in localities where the dust clouds were densest, filling the tents and kitchens and covering the food supplies. The dust had undoubtedly some influence in the causation of pneumonia, and more particularly in determining the frequency with which it was attended or followed by suppurative pleuritis.

Many of the soldiers left their State camps affected by bronchial catarrh, which constituted a potent predisposing cause to pneumonia. This was particularly true of some of the regiments from Illinois. Naturally the first regiments arriving at Camp Thomas were quartered near the great thoroughfares of travel and those arriving later in more remote parts of the camp. It is a noteworthy fact that those regiments farthest away from headquarters were almost free from pneumonia, while those nearest the center of travel furnished the largest number of cases. The cool nights, the lying on the moist ground and the inadequate supply of blankets did their share in serving as potent exciting causes. Some definite information in reference to the distribution of the disease can be gained by considering the location of the division hospitals, and the number of cases of pneumonia treated in each one of them. The division hospitals were located as near the center of the respective divisions as possible.

The First Division Hospital was established on the Lafayette Road, about three-quarters of a mile from the headquarters of the corps. The Second Division Hospital was established about two miles from head-

quarters and about one-quarter of a mile from any principal thoroughfare, the Brotherton Road being the nearest one. But few of the regiments of this division were encamped on roads subject to much travel.

The Third Division Hospital was located at the junction of the Alexander's Bridge Road and the Jay's Mills Road, about two miles from headquarters. Some of the regiments of this division were quartered on roads which were used by the wagon trains hauling water, consequently frequently exposed to clouds of dust.

During the latter part of May and the month of June forty-six cases of pneumonia developed in the First Army Corps. These cases were distributed among the division hospitals as follows: Hospital at Headquarters, 4 cases; First Division Hospital, 32 cases; Third Division Hospital, 10 cases. The Second Division Hospital was not established until the middle of June, and from that time on until the end of the month not a single case of pneumonia was reported. Careful inquiry at the regimental hospitals failed in finding a case previous to the establish-

ment of the division hospital. Five of these cases were operated upon by myself: four at the St. Vincent's Hospital and one at the Leiter Hospital. The following case represents the pathologic conditions found in these cases as well as the surgical treatment which was resorted to in meeting the indications of the empyemic complication:

W. F., private, Third Ills. Vols., was taken suddenly ill while on drill, May 30. The attack was initiated by nausea, vomiting, dizziness and a sense of great prostration. On the following day severe diarrhea set in, which, in connection with persistent vomiting and intense headache, influenced his physician to transfer him to the division hospital. At that time physical examination revealed a well-marked bronchitis. In the evening he had a decided chill; temperature 103.

June 1. He complained of severe pains in his chest and back, cough dry and hacking, sputum tinged a rusty color. Diarrhea continues; slight delirium; temperature 99 in the morning, 103 in the evening.

June 2. Chest pains not relieved, sputum more deeply tinged. Temperature varies from 101.5 to 103.

June 3. Diarrhea under control; cough and expectoration unchanged; delirium and temperature about the same.

June 4. No material change in the condition of the patient; tongue dry and dark brown.

Daily examinations of the chest did not reveal any signs of

Record of variations of temperature beginning May 31, 1898, at Leiter Hospital.

ment of the division hospital. This was the division encamped almost entirely away from any of the principal roads, hence least subjected to dust-infection. It will be noticed that 32 cases, or nearly 70 per cent. of the entire number, occurred in the First Division regiments. Out of these forty-six cases six died, or a mortality of 13 per cent. The six fatal cases came from the First Division. In three of these fatal cases death was caused by the progressive extension of the septic pneumonia, and in the remaining three death was caused by complications. In one case death was attributed to a typhoid condition; in two to cerebrospinal meningitis. The septic nature of the cases of pneumonia which developed in the First Division is best shown by the frequency with which empyema attended or followed the pulmonary disease. In this division empyema complicated the pneumonia in nine out of the entire number of thirty-two cases, equal to 28 per cent. Four of these cases were treated at the Leiter Hospital and four at the St. Vincent's Hospi-

tal, Chattanooga. Five of these cases were operated upon by myself: four at the St. Vincent's Hospital and one at the Leiter Hospital. The following case represents the pathologic conditions found in these cases as well as the surgical treatment which was resorted to in meeting the indications of the empyemic complication:

June 7. Patient delirious most of the time; cough harassing, and copious expectoration of rusty sputum. Temperature rose rather suddenly to 105.

June 8. Cough less troublesome, sputum more scanty; subjective symptoms improved. Patient was transferred to the Leiter General Hospital, when on his arrival the temperature was found to be 102.4. The medication at this time consisted of strychnia in small doses, muriate of ammonia 5 grains every four hours, alternated with 3 drops of turpentine. Under this treatment the temperature was reduced 1½ degrees during the first day, 2 degrees the second, and 1½ degrees the third day, becoming normal June 11. Carbonate of ammonia was substituted for the muriate at this time.

From June 12 to 18 the temperature ranged one degree above and below normal. The pulse, which had been 118 beats per minute and feeble on his admission to the Leiter Hospital, became fuller and stronger and diminished in frequency to 80.

June 19. Temperature suddenly rose in the afternoon to 102, pulse 96.

June 20. Examination of chest showed absolute dulness on the right side, extending as high as the fourth rib. The appearance of fever after a few days of complete defervescence

and the rapid increase of the area of dulness, displacement of the apex-beat to the right, as well as a marked bulging of the lower intercostal spaces, left no doubt of the existence of empyema. The symptoms indicating the presence of this complication were so evident that it was not deemed necessary to resort to an exploratory puncture to verify the diagnosis.

In all of the cases of pneumonia complicated by empyema that came under my personal observation, the disease pursued a very similar course to the one described. The clinical symptoms were characterized by their severity. The patient's general condition left little doubt as to the septic nature of the original disease. As in the case detailed, the suppurative pleuritis commenced two to three days after the pneumonic symptoms had subsided, its onset being announced by a rise of temperature and the appearance of local and general symptoms, suggestive of the existence of a suppurative affection.

It is more than probable that in most of these cases the pyogenic microbes, which eventually attacked the pleura and caused the suppurative process, entered the lungs at the same time and in the same manner as the microbes which caused the pneumonia. The bronchitis and diarrhea which initiated the disease were plain evidences pointing in this direction. In some of the cases in which the pneumonia pursued a more typical course, the subsequent suppurative pleuritis was caused by a secondary mixed infection. All cases of empyema which were subjected to operative treatment were characterized pathologically by the presence of an abundant fibrinous exudate, which covered both the visceral and parietal pleurae, and, in the form of large fibrinous masses, mixed with the thick cream-like pus. The purulent accumulation occurred rapidly, filling the pleural cavity in a very few days. Displacement of the heart, enlargement of the chest and bulging of the intercostal spaces were the most significant local signs indicating the presence of a large quantity of pus in the cavity of the chest. The right and the left sides were affected with about the same frequency. In one case the pleuritis was limited, leading to a circumscribed empyema in the left side. The abscess occupied the lower and posterior part of the chest. In performing the radical operation in this case, a section of the tenth rib, about three inches from the spinal end, had to be excised. The location of the empyema was determined beforehand by systematic exploratory punctures, the first two punctures yielding negative evidence. As a rule, expansion of the compressed lung followed soon after the operation, showing that resolution had occurred before or after the pleuritic complication appeared.

In some of the cases suppuration was scanty after the operation; in others it was abundant. In the former event a process of repair set in promptly; in the latter case it was retarded. The final process of obliteration of the pleural cavity was accomplished by granulation, cicatrization and cicatricial contraction. Evacuation of the pus and drainage were always followed by a fall in the temperature to normal, or nearly so, accompanied by symptoms denoting rapid improvement of the patient's general condition. In two of the cases the physicians in attendance were misled in their diagnosis by the absence of fever. The pleuritis was initiated as usual by a rise in temperature and other febrile disturbances, which subsided in a few days, the patients feeling well with the exception of the complaint of embarrassment of the respi-

ration. In one case the respiration was so much interfered with by the copious pleuritic exudate that the lips were blue and the pulse almost imperceptible—conditions which necessitated the performance of the operation without an anesthetic. We relied in this case on strychnia and whiskey to counteract the immediate effects of the operation. In the absence of such contraindications ether was used as an anesthetic, aided by the administration of some heart stimulants immediately before the administration of the anesthetic.

OPERATION FOR EMPYEMA.

The existence of an empyema in the adult is a sufficient indication for the performance of a radical operation. Puncture and removal of the pus by aspiration may succeed occasionally in mild cases of suppurative pleuritis in the case of children; seldom, if ever in the adult. Operative treatment should be instituted as soon as a diagnosis can be made. Unless the signs and symptoms are conclusive, the diagnosis should be verified and the pus accurately located by an exploratory puncture, as was done in most of the cases operated upon in Camp Thomas. Nothing is gained and much is lost by postponing surgical treatment until the accumulated pus has increased to the extent of producing serious and often irremediable compression of the lung on the affected side. The plastic exudate, which is often copious, as in all the cases forming the basis for this address, is another source of danger in case the operation is not promptly performed, as it creates conditions unfavorable to the subsequent expansion of the compressed lung and extenuates indefinitely the infection.

In view of the pathologic anatomy presented by the cases of empyema which constitute the basis for this paper, it must be admitted that the only rational treatment consists in opening the pleural cavity freely and in establishing efficient tubular drainage. Intercostal incision and drainage do not enable the surgeon to remove the large fibrinous masses which play such an important rôle in maintaining suppuration and in preventing speedy obliteration of the pleural cavity. The fibrinous exudate contains pus microbes, and unless removed at the time the operation is performed, serves as a nutrient medium for their growth and reproduction and interferes mechanically with pulmonary expansion and speedy obliteration of the pleural cavity by granulation and cicatrization. One of the important modern indications in the surgical treatment of empyema is to remove the inflammatory product as thoroughly as possible, and this can only be done after opening the cavity sufficiently to remove by mechanic measures the infected exudate. In recent cases resection of two inches of one rib at a point where drainage will be most effectual will afford sufficient room to subject the pleural cavity to a thorough removal of the inflammatory exudate. With the exception of the case of circumscribed empyema, we opened the chest in the axillary line where the ribs are nearest the skin and usually resected the seventh rib. With one exception, aspiration was performed a day or two before the operation for the purpose of securing partial pulmonary expansion before admitting air into the pleural cavity.

Preliminary aspiration is of special value in the treatment of large empyemic cavities. The surface of the entire chest was thoroughly disinfected and every care taken to carry out full aseptic precautions

during the operation. The opening of large pus cavities is attended by great responsibility, and this is more especially true in empyema, as secondary infection is liable to occur unless the operation is performed under strictest aseptic precautions. If an anesthetic is given, the greatest watchfulness is required to guard against accidents. I always prefer to perform the operation under partial anesthesia, and I am very partial to strychnia and alcohol as valuable adjuncts in minimizing its immediate and remote dangers.

I place the patient partially on the opposite side with the chest slightly raised, and the arm on the side to be operated upon raised to the side of the head for the purpose of increasing the width of the intercostal spaces. I expose the rib to be resected by a slightly curved incision with the convexity directed downward, beginning the incision at a point corresponding with the upper border of the rib, carrying it in a gentle curve to the lower border, and terminating it at the upper border at a point about four inches from where it started. By reflecting the cutaneous shallow, oval flap in an upward direction, the muscular covering of the rib is exposed. A straight incision over the center of the rib, about three inches in length, is then made down to the bone. With an elevator the periosteal envelope with the tissues attached to it is then separated, taking care to lift out from its groove the intercostal artery with the tissues to be reflected. After laying bare the rib to the extent of at least two inches, the rib is lifted forward with the elevator and excised with a strong pair of bone-cutting forceps. If the diagnosis is positive, all that remains is to make an incision with the scalpel in the center of the periosteal trough, large enough to admit the tip of the index finger.

The evacuation of the chest contents should always be done slowly; this can be done most effectually by interrupting the flow of pus from time to time by inserting the index finger into the pleural incision. After evacuation of the pus and loose shreds of fibrinous material, the pleural cavity should be carefully examined by direct inspection and digital exploration. Plastic exudates attached to either pleura must be removed as thoroughly as can be done with finger and a small gauze sponge held securely in the jaws of a pair of long, preferably slightly curved, forceps. The membranes should be removed by mopping and not by the use of sharp instruments. Scraping of the pleura with a sharp spoon is superfluous and occasionally detrimental. In acute cases I have often noticed quite free hemorrhage from the pleural surfaces even after gentle efforts to dislodge the adherent fibrinous exudate. Should troublesome hemorrhage follow the procedure, packing of the pleural cavity with one long strip of plain sterile gauze should at once be resorted to. The space below the drainage opening is packed first, and if the hemorrhage is not arrested, the balance of the cavity is packed from above downward.

Tubular drainage is the ideal method of draining a suppurating pleural cavity. I use for this purpose two fenestrated tubular drains, the size of the little finger, about four inches in length and securely fastened together with a large safety-pin. Drains have been repeatedly lost in the pleural cavity for want of resorting to this simple precaution. After inserting the tubular drain, the external wound is sutured in the usual manner. The curved incision, as described

above, not only exposes the ribs more freely than the straight incision, as usually practiced, but it is also much better adapted for prolonged drainage.

I never irrigate the pleural cavity the day the operation is performed. I do so later, provided suppuration continues. In case irrigation of the pleural cavity becomes necessary, care is necessary in the selection of the antiseptic solution; carbolic acid and corrosive sublimate in the usual strength are dangerous, and should never be used. I make use of either a saturated solution of the acetate of aluminium or Thiersch's solution. Both of these solutions are efficient as an antiseptic and non-toxic even when used in large quantities. The value of the double drain is made apparent when it becomes necessary to irrigate the pleural cavity. By placing the patient on the opposite side, the fluid which enters the chest through one tube escapes through the other as soon as the cavity is full, thus washing it out thoroughly. By placing the patient on the affected side the cavity is emptied, when the same procedure is repeated until the solution returns clear. The solution used should always be heated to blood temperature, as irrigation with a cold solution is fraught with danger.

The external dressing should consist of a thick cushion of sterile gauze and absorbent cotton to absorb the fluid as fast as it escapes, and to provide the wound with a filter to prevent post-operative infection. The best way of keeping the dressing in place and to prevent the entrance of unfiltered air into the cavity, is to substitute for the ordinary bandage the rubber webbing bandage. Change of dressing and antiseptic irrigation become necessary as often as the dressing becomes saturated. For the purpose of obviating frequent changes, the dressings should be ample.

As the cavity diminishes in size the drains are shortened from time to time, and sooner or later one of them can be dispensed with. Premature removal of the drain is often followed by relapse. Drainage must not be suspended until the surgeon can satisfy himself by careful examination that the pleural cavity has become obliterated.

Should the lung fail to expand sufficiently in the course of a few months to place the cavity in a condition for definitive healing, Schede's thoracoplastic operation is the operation of choice, as Estlander's multiple rib resection has not yielded the expected results in the practice of many operators, including my own. It is well for the surgeon to keep close watch of the size of the cavity during the after-treatment. It has always been my custom, at stated intervals, to place the patient on the opposite side, then fill the cavity with one of the antiseptic solutions used for irrigation, then evacuating the chest by reversing the position and measure the quantity of fluid removed. By recording the results of such measurements, we are in a position to judge with mathematic precision the size of the cavity, and determine whether or not healing is possible without further and more serious operative interference. Prompt and progressive improvement followed the operation in all of my cases of empyema operated upon in Camp Thomas. In most of the cases suppuration was soon under control, followed by speedy pulmonary expansion and permanent healing of the empyemic cavity by granulation. In two of the cases a recent examination made by Dr. A. F. Lemke showed that the patients recovered their former health.

Our limited means of making a satisfactory bacteriologic examination of the inflammatory product made it impossible to ascertain in each case the nature of the microbic cause of the suppurative complication. In two of the cases, inoculation of proper nutrient media resulted in an abundant growth of the staphylococcus pyogenes aureus. I have but little doubt that in most, if not in all cases, the suppurative pleuritis developed in consequence of a secondary infection with pus microbes, probably in most instances with the staphylococcus, as indicated by the clinical course of the disease and the nature of the inflammatory product. The etiologic relationship of dust to pneumonia, and especially the pleuritic complication, must be regarded as established by the facts related above.

The influence of dust in the causation of pneumonia and suppurative pleuritis acts in two ways in the causation of these diseases: 1. The mechanical irritation of the bronchial mucous membrane resulting from the presence of ordinary dust renders the epithelial layer of the bronchial mucous membrane more permeable to the entrance of pathogenic microbes. 2. Pathogenic microbes, and in this case pus microbes, are suspended in the dust and find with it entrance into the air-passages.

The importance of early radical operative intervention in the treatment of empyema can not be overestimated. The only efficient treatment in such cases consists in opening the cavity of the chest freely by rib resection, removal of inflammatory product and establishing free tubular drainage, followed by safe and efficient irrigation, should subsequent suppuration demand it.

CHAIRMAN'S ADDRESS.

Presented to the Section on Stomatology, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY G. V. I. BROWN, M.D.

MILWAUKEE, WIS.

It is my pleasure, as your chairman, to give the first greeting to the Section of Stomatology of this Association, and also to our confrères in joint session, the Colorado dentists, among whom I trust it may be the inaugural of long and beneficial intercourse. Stomatologists in fact we have long been, I am sure, but to be so recognized by title is a long step forward in the direction toward which, from year to year, those who have carried the burden of the vast amount of work necessary to this Section have labored, and is certainly worthy of general congratulation. We no longer serve under the somewhat limited, almost ambiguous term of "oral surgeons," but are hereafter to be recognized as those having understanding of the science of the mouth, a tribute complimentary to the scientific character of papers which, published side by side in the journal of this Association with the essays of the most learned medical and surgical lights of the day, have gained the respect of the other branches, having given those who treat diseases of the mouth their only opportunity to exchange ideas directly with the medical world, the influence of which, in discovering to it the possibilities of applying the technique of the skilful dentist, in conjunction with a knowledge also of surgical procedure and medical science, can not be overestimated.

The address of your chairman, Dr. Andrews, last

year, in following out the idea of an anniversary celebration, has told the story of the earnest few, the authors of our being, so completely that reference to the history of the Section is unnecessary. It seems, however, that his suggestion as to the necessity for united efforts being made in the interest of sanitation, in having the mouths of school children regularly examined by regular practitioners of dentistry and, in a general way, instruction given as to the care they ought to receive, is worthy of reiteration in order that the idea may not escape entirely. An effort made in my own home during the past year to carry out the plan has not proven thus far of any practical value, but constant agitation and repeated effort will undoubtedly accomplish much that is at first apparently impossible.

There is another line of duty to which I would respectfully call your attention, which also calls for united effort in order that our objects may be furthered. As we all understand, the essential idea of this Section is that dentists shall also be graduates in medicine, therefore properly entitled to the benefits accruing from association and consultation with physicians. There is a difference of opinion as to the advisability of having the student take the medical degree first and the special degree in dental surgery afterward, or vice versa, but there can be no question of the importance and little, if any, of the necessity of having both. Unfortunately for this desideratum, the difficulty of accomplishment is most unfavorable, owing to lengthening of the required course of instruction for recognition by the National Association of Medical College Faculties and the National Association of Dental Faculties; while with each it is a mark of progress toward higher education, and the probable effect, so far as the Section of Stomatology is concerned, and the advance of both professions into that interlying field, fast becoming of value to each, bids fair to completely abort, or at least inhibit a promising growth in future usefulness. The number of years of study required is becoming, not only quite beyond the possibility of the average student to attend, but more extensive than the benefits to be derived from the practice of our special branch will warrant, in comparison with other departments of medical science. Therefore, the natural result will be that the student of the near future must decide either to be a dentist, pure and simple, without a degree in general medicine, or be obliged to become an oculist, an aurist, a rhinologist or a practitioner, limited to some one or more of the other special fields of medicine for which he can equip himself with one year, or perhaps a little more, of study after graduating at some medical college, and even if he takes a short postgraduate course abroad, as so many do, will yet have perhaps expended less time and money than would be required to complete his attendance at a reputable dental school.

When this Section was first organized and recognized by the AMERICAN MEDICAL ASSOCIATION it was possible to complete the required course for the degree of D.D.S. in two years, then get an advanced standing in the medical college and receive the degree of M.D. in one year afterward. Today the National Association of Medical Colleges requires four years for graduation, and the dental faculty association three years, with the prospect of an additional year in the near future—now under consideration. It has already become a matter of some difficulty for a graduate of

either school to be allowed advanced standing of even one year in the other, so that under the most favorable circumstances it requires five years' study to acquire both degrees at the present time, with every likelihood of the sixth year being added. Thus it seems not altogether improbable that, without adjustment of the difficulty, the Section of Stomatology may become almost limited in its active usefulness to the lives of present members.

I believe the good work done by this Section already, and the far-reaching benefits resulting from the great advance due to an understanding of the nature and treatment of diseases of the mouth, applied in a scientific manner, by association with other departments of medicine, have established the fact beyond the peradventure of a doubt, that from a clinical and scientific standpoint it has earned the right to urge upon each side that an effort be made to further the protection of further influence, by modifying for the purpose, in a reasonable manner, the exacting requirements upon those who desire to be fully equipped with both degrees. To take the medical graduate in one year through the necessary technique of operations upon the teeth, in order that he may become an accomplished operator in that short time is almost impossible. To require students of the dental college to take a full course in anatomy, physiology, chemistry and all the fundamental branches, the same as medical students, has been proven to be, for the average individual quite too much in addition to his mechanical instruction, having a tendency to cause neglect of the latter, but in dental schools that are connected with medical colleges and universities, it is always possible for a student, willing to make unusual effort, to take the regular course with the medical student, and at the same time fulfill the requirements of his dental studies and laboratory work. For such, the reward and encouragement should be that, having passed the same examinations, with an average equally as high as his medical brother, he will receive credit for those branches and be exempt from future examinations, so far as they are concerned, when he undertakes the study of medicine, also that the dental student so educated shall receive some mark of distinction in his degree, which will serve to note the difference in his favor over other graduates in dentistry, and that the holder of such a degree be allowed to finish his course of medicine in at most two additional years. On the other hand, medical students at colleges where both branches are taught may avail themselves of the opportunity to do required work under the instructions in dental operative and prosthetic technics, and having done so, be admitted to the senior year of a dental class with credit allowed them for this work done, even though it had been done while a matriculate in the school of medicine. Such an arrangement would in no wise tend to let down the bars in either profession, and would without doubt encourage many students to make this effort, the enviable result of which would be more fully educated men and a greater number brought up directly in line with the purpose of this Section.

The bibliography of the past year, in its valuable additions to science from members of our profession, particularly of this question, invites discussion in a most alluring manner were time and and your patience sufficient, but in order that all may not escape, and because of special interest to myself as bearing upon a subject, the clinical aspect of which has for some

time been the object of my investigation, I desire to call attention to the photographs of microscopic sections recently shown by Dr. J. Leon Williams of London, in line with others by Talbot and statements by Black demonstrating that the blood- and nerve-supply of the peridental membrane of the tooth is something quite different from that which is depicted in the illustrations of Gray and other anatomic authorities, clearly showing as they do, nerve filaments and nerve fibers communicating directly with the peridental membrane of the tooth from the main nerve-supply, a most important clinical consideration. Last year before this Section, in my paper on "The Hyperkinesis of the Muscles of Mastication," I endeavored to call attention to the fact that tooth-grinding or extreme pressure of the jaws, caused by irritation of the nerve-centers controlling those muscles, was a common etiologic factor intimately associated with neuralgia of the trigeminus, and other pains of the head, particularly in those forms of the headache which are the accompaniment of neurasthenic conditions. Since the writing of the paper referred to a number of very interesting cases have come under my charge, in which the character of the pain had been mistaken for reflex of uterine diseases, and for which there had been one or more operations performed in the hope of relief, but without success, which in every case was afforded by correction of the source of irritation, discovered to be in the mouth. In one case there was evident a condition such as might be attributed to what is known as eye-strain, and I desire to introduce at this time the expression "jaw-strain," as applied to a similar general condition resulting from an irritable weakness of the nerve-centers controlling the muscles of mastication and the trigeminal branches directly affected which, without going into more minute explanations, are easily accounted for by an examination of the photomicrographs referred to. Since through the peridental membrane we have as direct a connection with the main nerve-supply as had long been supposed to be through the apical foramen of the pulp of the tooth only, tooth-grinding could have produced an equivalent condition to that of eye-strain, which several writers claim to be the cause of at least 50 per cent. of all cases of hysterio-epilepsy and other disorders of nervous origin.

Full of hope, strong in the faith that the essays before us—to which in closing I invite your attention—will add their mite to benefit mankind in the alleviation of suffering, and filled with a deep sense of our several obligations, I thank you for courteous attention, and the honor of addressing you in my present capacity.

ORIGINAL ARTICLES.

DIET IN DISEASE.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY CHARLES H. SHEPARD, M.D.

BROOKLYN, N. Y.

There is no function of the human body so essential to its existence as the process of digestion, and it may be stated as a fundamental proposition that those foods having a natural proportion of the elements of nutrition are the most desirable for maintaining a correct balance of the system and retaining its vigor.

No infringement of this law is tolerated. When we attempt to nourish the body on any one element of food, such as starch, sugar or fat, it is sure eventually to prove a failure, and bring on gastric disturbance and functional incapacity. Whenever an excess of even the simplest and most appropriate kind of food is taken, the digestive organs become overtaxed. If this excess is persisted in, nature refuses its assistance and allows that which it can not utilize to remain unappropriated, from lack of digestive fluid to complete the process, and from being unacted on it soon ferments and entails manifold and untoward consequences. The large amount of fluids secreted by the different glands and mucous membranes prevent putrefaction and aid in the distribution of nutriment to the proper channels to sustain life. This shows the intimate relation between diet and disease. In fact, a carefully regulated diet has, in numberless cases, proved one of the best, if not the very best, corrective of disease.

In this land of plenty there is an enormous waste of food material by all classes, but of all wastes the worst is that of excessive eating, not only because it destroys the food, but for the reason that it produces many of the diseases that are attributed to other causes. When we consider how much suffering of body and mind results from systematically abusing the stomach, it will be understood and admitted that our people are great sinners against the laws of health. It is acknowledged by the best authorities that mankind as a rule in this country partake of about double the quantity necessary for the highest condition of health, and it should readily be seen that plethora can be quickly and safely reduced by abstinence, with water, warm or cold, to dilute and wash out the surplus. Inasmuch as our bodies are made up of what we eat and drink, and our health and happiness is largely dependent upon the proper selection of our food, no reasonable mind can for one moment doubt that our health is made or marred by that selection, and it becomes us as sensible beings to make a study of the subject, if haply we may thereby secure the maximum of physical vigor and intellectual force, for it is in proportion to his mental clearness that a man succeeds or fails in the many struggles of life. Both the quantity and quality of food are important, so that mankind shall be neither overfed or underfed, and thus preserve a happy medium that contributes to the most perfect condition of health.

Just so soon as people learn and obey the laws of health will they begin to realize and obtain the fullness of days which is their due, and which is estimated by many to be over one hundred years. If man had what he is entitled to, the birthright of a clean, vigorous constitution, which never comes of reckless parentage, and then could be brought up under the most sanitary influences, this would be the minimum of his years. The time will certainly come when it will be considered a disgrace to be sick, for that condition is only brought about through a transgression of nature's laws.

It is evident that as we progress in intelligence and refinement our food standard changes. Perhaps it would be more correct to state that as man improves in his dietetic habits he will advance physically, mentally and morally. Today, not only is less alcohol used with food than in former years, but fruits are more and more in demand, and it is equally true of grains and vegetables, and doubtless many of the

great variety of nuts will be found desirable, to the further exclusion of animal food. Nuts are fat-forming, heat- and force-producing, and more nutritious than animal foods, and are not open to any suspicion of disease-production. The nut-growing industry is of increasing importance and will be found largely remunerative in the not remote future. Then nuts will take high rank among the foods of our people. As compared with the nourishment they give, fruits and nuts have the least proportion of earthy salt. Animal flesh comes next, then vegetables, and fourth in rank we have cereals and pulses, which are shown to have the largest amount of earthy matter.

A union of the cereals with fruit, vegetables and animal food has so far produced the most satisfactory results, though the mass of mankind enjoy life and are well nourished without animal food. The educated Brahmin lives very simply, often upon one meal a day. As man advances toward a higher plane, he inevitably tends toward what, for want of a better term, may be called vegetarianism. Those capable of the greatest endurance subsist mainly upon the products of the earth. The Grecian athletes, who made the glory of the Olympian games, were trained on vegetable food. Those were the days when the Grecian outlines were the standard of physical beauty, both in face and figure. The eminent Professor Virchow says, "the future is with the vegetarians."

The first requisite in our diet is that of pure water. Man can live many days on water alone, for we are mostly made up of water, and disease can be quickly washed out of the system by taking nothing but pure water. This has been many times demonstrated. Impure water has been the cause of some of the most fatal epidemics. Another important requisite is that of pure milk. In infancy we live on milk alone, which may be called a perfect food, containing as it does all the elements of nutrition. Another important requisite is good bread, but when it is made principally from the starch portions of the grain, with the phosphates and other nutritive elements excluded, it is very far from being the "staff of life," as it is sometimes termed. The most perfect bread is made of the entire wheat, not too finely ground, and mixed with pure water, adding nothing but a little salt, and then baked in a quick or hot oven. This is the primitive form of breadmaking and contains all the nutriment of the grain. The greater the departure from this standard the more undesirable, from a health point, does the bread become. The more bread is raised by leaven or yeast, the greater is the destruction of the elements of nutrition. When we consider how much the popular bread of the day is robbed of its life-giving principle, it is not so much to be wondered at that the unsatisfied craving for perfect nutrition leads to the saloon and a thousand other ills. More than one physician thinks that the enormous increase in diabetes in this country is due to our modern way of living, and particularly the use of fine flour in bread and other preparations, which is deprived of a large proportion of the most important elements of nutrition. It has been many times demonstrated that children fed largely on white flour bread are found to be deficient in the bone-forming elements, and this is plainly shown in the teeth. Another thing that militates against the teeth of our people is the habit of using so much soft food. If we do not use our muscles they become weak and flaccid; so with the teeth, they decay and become

useless, the gums soft and the teeth loose. The reason we need the tooth brush so much, and have to call upon the dentist so often, is because of the large use of food that does not require mastication.

The most untoward results come from feeding infants and children with unsuitable elements of food, and at times allowing them substances such as common salt and lime, that by no possibility can be utilized as food. That so many live after passing through the ordinary ordeal demonstrates the wondrous vitality and power of resistance of the human race to morbid influences. Chlorid of sodium, or common salt, is by no means identical with the salt contained in fruits and vegetables; in these it has been organized and fitted for appropriation to animal life. From recent experiments in Europe, there is strong presumptive evidence that common salt, in excess, produces renal troubles leading to Bright's disease. Lime also, an important element in the formation of the teeth and bones, can not be utilized in the crude form of mineral lime; on the contrary, it delays and interferes with digestion, but in the organized form, as found in the whole wheat grain and other cereals, as well as in fruits and vegetables, it is prepared in the most perfect manner possible for the building up of the human framework, as these elements become digestible only after their assimilation by plants suitable for human food.

While condiments and seasonings are very popular, the fact remains that they are entirely innutritious, and serve to foster an artificial appetite. They destroy our appreciation of the finer flavors of the foods. At the same time they prove injurious to the health, by irritating the lining membranes of the digestive tract, and thus creating as a natural sequence an artificial demand for alcoholic mixtures. It is said of one of the Roman emperors that his taste became so vitiated that his food was necessarily seasoned with asafetida, in order that he might realize some taste of what he ate. Undoubtedly many of the vices that injure society and eventually result in crimes have their beginning at our own tables. We certainly can not expect to build up a strong vigorous constitution, capable of resisting disease, by feeding on ice cream, rich pastries and sweets. They do not furnish the bloom of youth. On the contrary, it has been found by reliable experiments that by providing the kind of food that goes to the nourishing of blood and muscle, the development of children has been forwarded to a remarkable extent.

Dr. Springer of Berlin announces that extracts from cereals, obtainable everywhere, are the best bone builders, and therefore well adapted to the growth and perfection of children. Here is his recipe: "Take two soup-fuls each of corn, barley, oats, rye, maize and bran, boil in four quarts of water three hours, allow to cool and then strain. If necessary add enough water to make a quart. A palatable yellowish fluid is obtained, which may be improved by the addition of milk for children." The results with several children placed under his care surpassed his anticipations. This has the merit of being equal in value to any of the extensively advertised food-nos-trums of the day, and is much less expensive. Secret foods should no more be encouraged than secret medicines, for some of them are simple frauds, particularly the so-called diabetic foods, and others are dangerous to the sick and well alike. The worst of all are the alcoholic beverages masquerading under the name of

malt. The best and most economical food materials for universal consumption are those in common use, and which need no fancy names. One authority says, in an attack of summer diarrhea in children under two years of age, all albuminous and starchy foods should be prohibited. It is the mature opinion of expert physicians that at such times, milk and the milk foods only tend to furnish fresh fuel for the growth of pathogenic bacteria in the gastro-intestinal tract. Give instead nothing but toast-water or barley-water for thirty or forty-eight hours. They contain plenty of nutrition for such conditions, and rarely produce any disturbance.

The list of foods that are said to be useful for this or that disease is almost unlimited, from onions, spinach, asparagus, cranberries, lemons, to figs, apples, grapes and prunes. Eczema has disappeared upon a discontinuance of starch foods and a substitution of fresh and dried fruits, milk, eggs and olive oil. The fact that a special line of diet is often curative for a large class of diseases is fully demonstrated by the different "cures" that are established in many countries, such as the grape cure in Southern France, the whey cure in Switzerland, and the koumiss cure of Southwestern Russia, and there are so-called fruit cures. Apples, oranges, lemons, bananas, prunes, tomatoes, etc., have been utilized at different times and in different ways for such purposes. The milk cure is another claimant for favor, and the dry cure, which consists in gradually reducing the amount of fluid taken into the system, also has its advocates, and there is the vegetarian cure as well as the beef and hot water cure, all of which have many followers, that seek the same end through different means. Fruits are among the most beautiful productions of nature, satisfying the esthetic taste as well as the palate. The purest water is contained in them. Their sugar is abundant and harmless, their acids cooling, refreshing and corrective of many untoward conditions of the body. The up-to-date physician recommends them largely, and they have been used to counteract the alcohol habit. The demand for fruit today is not only much greater, but a much superior quality is required than was prevalent thirty years ago.

An exclusive diet of fresh fruit for breakfast, without much change in the other two meals, has been found successful in relieving indigestion. One author claims to have cured himself of serious stomach troubles by means of this régime. The writer has made a trial of this plan for more than a year past with pleasing results. A short time ago a physician claimed that one meal a day of prunes was most beneficial to the nervous system, and would even make criminals more tractable. It is related of the Emperor Nero that he ate greedily of onions and garlic to improve his voice. Grapes are nutritious and the juice is said to contain sugar, tannic acid, bitartrate of potassium, tartrate of calcium, common salt and sulphate of potassium. The use of unfermented grape juice is deservedly increasing and taking the place of alcoholics in the practice of some of our ablest physicians. The delicious grape fruit is reputed to be a rival to quinin in the treatment of malaria, and the blackberry has long been considered as a sovereign remedy for summer complaints. The German analysts say that the apple contains a large proportion of phosphorus, and is admirably adapted to renewing the essential nervous matter of the brain

and the spinal cord. The old Scandinavian traditions represent the apple as the food of the gods, who when they felt themselves growing feeble and infirm, resorted to this fruit to renew their powers of mind and body. Those who cultivate the habit of eating a great deal of fruit are the gainers both in health and appearance, though it is well to heed the Spanish proverb, "Gold in the morning, silver at noon, and lead at night."

A water diet, or an entire abstinence from solid food for a limited time, and using water freely, has proved efficacious in a multitude of cases, especially in removing old tumors and enlargements of certain parts, such as goiter, etc., showing that the inherent vitality was sufficient to relieve the system of disease when the overplus was cut off and the system permitted time to eliminate the morbid accumulation.

An English magazine reports of the Northumbrian women, who came of a large framed race, and whose work lay in the fields, that they were hearty and buxom on a diet of oatmeal and milk, but as having sadly degenerated, become paler in color, stunted in size, and less capable workers, because wheat flour had supplanted oatmeal, and cheap tea taken the place of milk. . . . Tea is injurious when taken with or shortly after meals, because the tannin it contains tends to coagulate the albumen of the food undergoing the process of digestion. . . . Meat, fine flour bread and tea are the staple articles of food for a large part of our foreign-born population, as well as for some of the natives, and their children are fed in the same manner when quite young. This form of diet produces as a result, a pale, sodden complexion, dull eyes, flesh with no firmness, and individuals without stamina. . . . Children are more sensitive to nervous stimulation than adults. Their nervous system is extremely delicate. Even a slight irritation in the alimentary canal is sufficient to throw the child into violent convulsions. Therefore neither tea nor coffee is a fit drink for children. It is more than probable that the common use of these narcotics during childhood and youth is one of the factors that in later years produce the army of neurasthenics. It is stated by travelers in Brazil that the free use of coffee by the inhabitants is bringing about an evident deterioration of the people. This is conspicuously shown in their complexions and their nervous systems. By irritating the nerves that govern the heart action, coffee quickens the circulation, and in many cases induces cardiac palpitation. There are a few persons upon whose nervous constitutions coffee acts in the same way as alcohol.

It is frequently noticed that both improper quality and quantity of food has directly produced disease. When the horse, the cow, and many other animals are sick from overwork or exposure, they refuse their food, and when they begin to eat it is recognized that convalescence is at hand. This object lesson is worthy of imitation by the higher animal, man. Just so far as a departure is made from the laws of health, will the penalty be suffered, and this calls to mind the fact that in the South the planters are attempting to utilize for their cattle some of the dregs of their sugar mills, called "black strap." This may apparently work well for a time, but as it is not their natural food, in the end it is liable to result disastrously, as has the feeding of cows on "still slops," only it may come in a different form of disease.

That life and health are appreciated as priceless is shown by the American public in a misguided man-

ner, when it pays two hundred million of dollars annually for proprietary medicines. "All that a man hath will he give for his life," but he who pays out money for patent medicines is paying more for death than life. More and more it is believed that strength of body conduces to strength of mind and morals. Young men and women gladly place themselves on a restricted diet when training for some game or enterprise, and thereby receive many an object-lesson in the value of certain kinds of food to enhance or destroy their powers of endurance. The judgment that this or that plan of diet is the proper thing to ensure success makes it a pleasure even to those who have been educated in a vastly different school. How much more will the great majority of mankind, when they come to realize that the problem of life is dependent on the kinds of food and drink they habitually use, learn to enjoy those things which the judgment of scientific research tells them are conducive to their higher development and health, and thus shall we not only find that a consistent diet aids in the cure of disease, but in a larger measure tends to the prevention of disease. As a rule, however, most of us learn these facts through the medium of painful personal experience. Certainly a subject fraught with such important consequences is worthy of earnest study, and happy are they who early learn the lesson, and thus avoid many of the pitfalls of our day, and pass on to a serene old age. A good authority says, "Every one dies before his time. This is not strange, for during his whole existence, from the cradle to the grave, a human being, even if in good circumstances financially, is surrounded by unhealthy conditions. He eats scarcely anything that is not adulterated, wears hardly anything but what is shoddy, and ignorantly neglects both personal and public cleanliness. 'Cheap, let's get it cheap.' Purity is the last consideration, and no matter at what age he dies, he has by this constant use of adulterated products, been deprived of several years of life." Most truly did Seneca say, "Man does not die, he kills himself." An English authority, in speaking of the alimentation of old age, says that in advanced years the stomach can no longer endure the strong food of former days. The period of decline is characterized by several changes, both in the voluntary and involuntary muscles of the body. A want of tone affects the circulation generally, the digestive system becomes weaker, and the mental powers share in the decreasing vitality. For healthy old age the body should be lean and spare, like that of a school-boy, the foods being reduced in quantity and animal food restricted. If the decline in energy is not met by a corresponding diminution of the demands upon it, the result is sure to be an accumulation of fat, and retrograde changes, producing gout and rheumatism. In advancing age the food consumed should approach that of youth, and in second childhood, a return be made to the bread and milk of early days.

The hereditary vigor with which all are endowed, some more and some very much less, is what may be called personal equation, and may easily explain how it is that some individuals can go on transgressing the laws of health in a most reckless manner and yet outlive others who are most scrupulous in the care of their health. The fact is that many of the latter have found themselves obliged to lead a careful life, else they would have to pass on altogether. Those who squander their stock of vitality, never see the fullness

of their days, and their children, if they are unfortunate enough to have any, are still shorter lived. It is what we eat and drink that makes or mars our condition. If we partake only of the pure, we shall be clean and pure throughout. If on the contrary we handle the unclean and attempt to build up with gross material, it will result in uncleanness, disease and death.

Those who are seeking to retain their health as well as those who desire to regain it, must necessarily observe simplicity in their diet, and uniformity in the time of meals: The highest efficiency of the forenoon work is not promoted by a hearty breakfast, nor is a hearty luncheon helpful to the afternoon duties. For those who are actively engaged during the day, the evening seems most desirable for the principal meal. For centuries this has been the practice of the people of many countries. Nothing should be eaten between meals, nor when the body is exhausted. Scientific experiments have demonstrated that fatigue is a disease, and that it is possible to produce the same symptoms in one animal by inoculation with the fatigued serum of another, showing that overwork produces an actual poison in the system. Worry is equally antagonistic to good digestion. A little rest and banishment of care in preparation for a meal should become a habit. It means preserved health and lengthened life. Three meals a day are ample, many flourish on two, and for some persons one meal a day has been found sufficient. With good food, and the best is none too good, well cooked, and well masticated, the stomach will do justice, especially if only gentle exercise is indulged in for an hour or more afterward. The digestive process usually occupies the stomach from two to three hours. It is always better to eat too little than too much, this is proved by common observation. Indigestion and nightmare are the penalty of over-indulgence. It is not in the quantity eaten that one is benefited so much as in the amount that is assimilated and appropriated for the needs of the body. Nature's mode of saying that the system is in no condition to take care of what may be forced upon it, is indicated by a want of appetite. The eating of candy is pernicious because of the sugar of which it is made and the inopportune times it is usually partaken of as well as the poisons which it sometimes contains. Nothing but pure water should be partaken of between meals or when one is inclined to enjoy exercise before breakfast. There will be more general invigoration if the stomach is not then called upon to work. The morning hour is a choice time for either mental or physical exertion, as it follows a long period of rest and recreation, and the stomach is quiet. Ordinarily there is but little work done after the late and hearty dinner, and as there is but little tissue waste during the hours of sleep, and that is the time when assimilation is most perfectly carried on, the body has then sufficient energy accumulated and stored up to meet all demands of the morning's pleasure or exercise. Any severe exercise is best taken on an empty stomach, because then the nervous energy is free and can be concentrated on whatever is desired to be accomplished, but when the stomach contains an undigested meal, a portion of vital energy is required for the work of digestion, and the more it is interfered with the worse it is for the individual concerned.

He who desires the supreme vigor of health, can have no use for alcohol, tea, coffee or tobacco. With pure water, well-chosen wholesome food, the exclusion

of all narcotics, and clean habits, together with our bracing climate and active pursuits, and the intermixture of the most enterprising races of the world, the American people should develop into the highest type of individual, family, and national life.

Fortunately the application of science to daily living is on the increase. Education is beginning to affect domestic life and in the near future our people may learn how to prepare a diet that will promote their health and development. The cooking schools are an indication of progress in this direction. There is no reform movement that appeals so directly to our daily needs as reform in diet, and herein the physician may find a field for some of his noblest work, when considered from the standpoint of morality and hygiene. What we shall eat, and what we shall drink, are ever recurring problems, and upon their wise solution largely depends the health and happiness of mankind.

THE IMPORTANCE OF A PROPER DIETARY FOLLOWING LAPAROTOMY.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June, 7-10, 1898.

BY C. W. WATTS, M.D., Ex-U. S. SURGEON.
MOBERLY, MO.

We propose to divide the subject into three heads: the dietary preceding, the dietary at the time of, and the dietary following the operation.

In order to be correctly understood we define a laparotomy to be any surgical operation performed upon the contents of the abdominal cavity at any point between the ensiform cartilage of the sternum and the symphysis pubis. And we propose to draw also the line of distinction between the operation performed on the organs contained therein and the other viscera, from the fact that the dietetics should be different from those necessary in cases of appendicitis, and operations performed upon the stomach and intestines. From an experience that covers a number of years, both in private and hospital practice, we are disposed to attribute the fatal results following operations on the abdominal cavity, more to the neglect of a proper dietary than to the direct result of the laparotomy. The surgeon who performs the operation is not to blame, but the one who has charge of the patient before and after the operation.

Before any operation is performed, for at least ten days, the patient should be prepared for the operation by a proper diet. The *prima vie* from the buccal cavity to the anus should be thoroughly emptied and cleansed by antiseptics and aseptics. Not a single particle of extraneous matter should be left. After this cleansing process has been completed a fluid diet should be commenced and kept up until the hour for the operation has arrived, when all dietary measures should cease until the operation has been completed; then a plain nutritious fluid diet should be kept up until the patient is dismissed. If it be a gastrotomy, a gastro-enterostomy, an enterotomy, or the removal of an appendix, the diet required in these cases is one by enema in preference to per orem, for reasons too plain to mention. On flushing the colon and as far up as the sigmoid flexure, you can give nourishment in all these flushings, with the exception of the one used to relieve the flatus and gaseous distention of the

intestines, which should be of simple hot water sterilized.

Supporting the system by nutritious enema is almost an unknown quantity among surgeons. Only those who have had practical experience are competent judges of its beneficial influence.

What we mean by nutritious enema are enema composed of sterilized milk, wine-whey, animal broths, etc., introducing into these enema any antiseptic that the surgeon may deem necessary. As surgeons we have not respected the digestive glands of the intestines sufficiently. We have not been disposed to give the stomach or intestines involved as much rest as they demand or require when being repaired by the surgeon. We have depended more upon the *vis chirurgica* and ignored the *vis medicatrix naturæ*, or the neglect of giving Nature, Dame Nature, the privilege of exercising her proper functions of recuperating energies. Many fatal results from the various laparotomies performed at the present day are the direct result of ignoring Mother Nature.

In operations upon the ovaries, kidneys, uterus and liver we can allow more generous diet, and can give well-digested fluids and solids, but in cases of stomach and intestinal operations we must adhere strictly to a fluid diet, given in small quantities and not too often repeated. Especially is this true where a section of the intestine has been removed. In this operation, as in a fractured rib, we require to apply adhesive strips to control the respiratory muscles. So in the enterotomies, we must prevent the peristaltic action by not inviting it by the administrations of food. Keep the stomach empty and let it rest until the intestinal wound has healed, which is but a short time. The laparotomist approaches his case with a good deal of confidence of success if his patient has had a careful dietetic preparation for the operation, and if he is certain that the dietetic precautions will be adhered to until convalescence has been completed. Too many operators are reckless and careless, and beget as a result, failure—failure invited by their reckless procedure. Too many are anxious to operate, regardless of the condition of the patient. Nowhere within the domains of surgery is the aphorism truer than in the saying, "haste makes waste."

Prepare your patients for the operations. I had rather amputate a limb upon a full stomach and bowel with assurance of success than to plunge my knife into an intestine or appendix with the same stomach and bowel loaded with their contents. Fortunately for humanity our noble profession is working up along this line. The day is not far distant when any form of laparotomy will be a comparatively safe operation, provided due regard has been had to the dietetic part of the treatment. More credit is due to that careful and painstaking physician who prepares his patient for the operation and then leads him safely through a proper dietary following than to the operator who does the work. All true surgeons will admit this. Examine the statistics of all laparotomies performed in this and the old country, and their history attests the truth. Of course we have no reference to those cases where an immediate operation is demanded. Fortunately, these cases are but the exceptions to the rule that governs proper treatment in the majority of cases. Every year has proven in its results the necessity of a proper dietary. Successful results are so sure to follow a proper dietary that it will soon be that any surgeon who neglects it should be held responsible and sub-

ject to prosecution for malpractice. There is no excuse under the heavens for reckless surgery, or for a surgeon who ignores the recuperative powers of nature. Who is so egotistic as to believe that his own surgical procedure will be vindicated by an offended nature? In the language of the immortal, illustrious Gross, "Respect nature, gentlemen, respect her. Relieve her of any dead parts, but for God's sake don't attempt substitution on her." Good, pure water is fine food, is easily digested and contains tissue properties. Good milk properly prepared is nutritious and safe, wine-whey is good, peptones and peptonoids are, to say the least, doubtful. I had rather my patient live on nothing than to use them in many cases.

Total abstinence is a fine diet in many cases. I never knew a laparotomy patient to die from starvation, but I have known them to die from overfeeding and neglect of a proper dietary.

THE IRRATIONAL AMERICAN BREAKFAST, JUDGED BY OUR PRESENT KNOWLEDGE OF THE PHYSIOLOGY OF DIGESTION.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY BOARDMAN REED, M.D.

PHILADELPHIA.

A witty Frenchman once remarked in substance that Americans partook of a dinner at breakfast time. It is a fact that on the continent of Europe it is the almost universal custom to break the fast in the morning with a very light meal consisting generally of little, if anything, besides rolls and coffee or chocolate. In no other country, probably is so hearty a breakfast eaten as in these United States. This may or may not be prominent among the hygienic faults that make Americans the most dyspeptic people in the world, but it is doubtless one of the causes. It is not reasonable to expect of the digestive organs as energetic and efficient work in the early morning as later in the day. The circulation is then less active and the nervous system not yet aroused to its fullest energy. One would naturally suppose, therefore, that the gastric, pancreatic and intestinal juices would not be so readily supplied in the quantities necessary to digest a very hearty meal at the breakfast hour as some hours later. Healthy, vigorous persons, who exercise much out of doors, can so adapt themselves, no doubt, to the habit of beginning the day with a heavy meal, and such persons may not be the worse for it; but it is different with dyspeptic and delicate people from whatever cause. These nearly always do better when given some light nourishment soon after awakening, their first substantial meal being taken at a later hour.

But this beginning of the day with a large complicated meal, scarcely less in extent and variety than the dinner, is not the only dietetic error of which the majority of our people are pre-eminently guilty. The relative order in which the average American takes the various kinds of foods entering into his generous breakfast is in defiance of the teachings of physiology. For example, it is well established that the digestion of starch is begun by the action upon it of the ptyalin in the mouth, as well as on its way to the stomach and during the first twenty or thirty minutes of its sojourn in the stomach—that is to say, while the gastric contents continue to be either

neutral or only faintly acid. The percentage of acidity at which starch digestion is arrested is stated differently by different authorities. Ewald and Boas found it retarded by .07 per cent. of hydrochloric acid and stopped by .12 per cent. Chittenden states that it is stopped by .003 per cent. This is reached by the normal stomach at the end of the first fifteen or twenty minutes after the beginning of a meal and in much less time when the secretion of hydrochloric acid is excessive, as it very frequently is with dyspeptics. When meat or an animal broth forms one of the earlier courses of the meal, the stomach contents become acid sooner than when milk or vegetables or cereal food is taken. It follows then that our amylaceous foods when forming part of a mixed meal should: 1, always come in the earlier courses, and 2, be as thoroughly masticated and insalivated as possible, so as to insure a prompt conversion into the forms of sugar in which only they are capable of absorption and assimilation.

The breakfasts which are served in most of the better-class American hotels, as well as in a large proportion of the wealthier private families in this country, begin with fruit (often highly acid kinds, such as grapes, oranges, or grape fruit), followed by some form of mush (largely starch) washed down with milk or cream, and with scarcely any admixture of the saliva. Enough of the sour fruit has often been taken before to render the stomach contents too acid probably for the digestion of the farinaceous foods to take place, even if any saliva—the only fluid capable of digesting them which they can encounter before entering the duodenum—had been incorporated with them. In the table given by Boas as representing the results obtained by both Ewald and himself, the organic acids are credited with a decided power of inhibiting the digestion of starch, though less than that exercised by hydrochloric acid.

The third course is usually beefsteak or mutton chops, which, in the normal stomach are almost sure to stimulate the secretion of the gastric juice to a degree which carries the acidity of the stomach contents above the starch-digesting point, supposing that the acid fruit of the first course has not already done this. To render it still more impossible that any further starch digestion should take place in the stomach at this stage of the breakfast, most persons, including children and healthy young adults having presumably an abundant gastric secretion, are usually encouraged to stimulate their peptic glands to a still greater secretion of the acid gastric juice by a free use of pepper, hot sauces or other condiments. If the meats were taken without accompanying or following starchy foods, it would not be so bad, but as a rule potatoes and hot bread in some form are eaten at the same time, and very often the meal is topped off with griddle cakes and syrup, one of the most indigestible and flatulent of the combinations of carbohydrates.

Another peculiarly American habit is the drinking of ice-water, often in large quantities, with every meal. This retards digestion, both by lowering the temperature of the contents of the stomach and by an over-dilution of the gastric juice. It is also capable of damaging seriously the delicate mucous membrane and ultimately causing catarrhal inflammation in patients otherwise predisposed to that affection. Is it any wonder that Americans so generally suffer from stomach troubles, and especially from the manifold consequences of the indigestion of starch?

If one must eat so large a meal in the morning, the viands might be served in the following order with much less risk of harm: 1, cereals well masticated and accompanied by rolls or bread and butter to carry down plenty of saliva; 2, potatoes with more bread and butter if desired; 3, meat or eggs, accompanied by a little salad; 4, fruit; 5, coffee or chocolate.

A NEW THERAPEUTIC MEASURE—THE ELECTRIC-LIGHT BATH.

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY J. H. KELLOGG, M.D.

BATTLE CREEK, MICH.

In a paper read before the American Electrotherapeutic Association, at its meeting in New York City, in September, 1894, I presented a description of a new method of applying heat to the body, using, as the source of heat, the incandescent electric light. I also gave in this paper the details of many experiments which I had conducted for the purpose of determining the physiologic effects of this bath, and also a comparison of the effects obtained by this bath with those obtained by the Turkish and Russian baths. The general conclusions to which I was led by this investigation were as follows:

1. The electric-light bath stimulates the production of the elimination of CO_2 in a very marked degree. In an electric-light bath lasting for thirty minutes, the percentage of CO_2 elimination during the last ten minutes was 5.13, as compared with 3.60, the average of CO_2 elimination before the bath. In a Russian bath the percentage of elimination was 3.96. In a Turkish bath of thirty minutes' duration the percentage of CO_2 elimination was 4.01.

2. The elimination of nitrogenous wastes, represented by urea, and also the elimination of total solids, was greatest in the Russian bath and least in the electric-light bath, doubtless the result of excessive skin activity.

3. The amount of perspiration produced by the electric-light bath was fully double that induced by the Turkish bath in the same length of time. The time required for the first appearance of perspiration was, in the electric-light bath, about one-half that in the Turkish and Russian baths. The reason for this is apparent when one recalls the fact observed by Bouchard, that perspiration begins when the temperature of the blood has risen .7 degrees F. above the normal. In a study of the physiologic effects of the electric-light bath in 1891, when I made my first experiments upon this subject, I found the internal temperature was raised by the bath 1.6 degrees F. in five and a half minutes, the surface temperature rising in the same time 2.3 degrees F.

From these facts it is evident that the electric-light bath raises the temperature of the blood more quickly than any other form of bath. The reason for this is apparent when it is remembered that the skin and other structures of the body readily permit the transmission of the radiant energy of the electric light, which, entering the body as light, becomes by the resistance which it meets transformed into heat. This heat is developed in the deeper tissues instead of being slowly carried in by conduction from the surface. The skin is, like glass, a poor conductor, but at the same time allows the passage of radiant energy

in the form of light. This fact explains the readiness with which perspiration is induced by the electric-light bath.

Prior to my own experiments upon this subject there had been, so far as I can ascertain, no scientific study of the physiologic effects of the electric light upon human beings. William Siemens, in 1880, published a paper giving an account of some very interesting experiments which he had made for the purpose of determining the influence of the electric light upon plant life, from which he drew the following conclusions:

1. That the electric light is efficacious in producing chlorophyll in the leaves of plants and in promoting growth.

2. That an electric center of light equal to 1400 candles, placed at a distance of two meters from growing plants, appeared to be equal in effect to average daylight at this season of the year (March), but that more economic effects can be attained by more powerful light centers.

3. That the carbonic acid and nitrogenous compounds generated in diminutive quantities in the electric arc produce no sensible deleterious effects upon plants enclosed in the same space.

4. That plants do not appear to require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected during the daytime to sunshine, and during the night to electric light.

5. That the radiation from powerful electric arcs can be made available to counteract the effects of night frosts, and is likely to promote the setting and ripening of fruit in the open air.

6. That while under the influence of the electric light, plants can stand increased stove heat without collapsing, a circumstance favorable to forcing by electric light.

Numerous observations have also been made by other persons, among whom the first to make experiments was Hervé-Mangon (*Compt. Rend.*, liii, 243). These experiments showed that the electric light was capable of producing the development of chlorophyll and inducing heliotropism, or the phenomenon of turning or bending toward the light. Experiments made in 1869 by Prillieux (*Compt. Rend.*, lxi, 410) showed that the electric light is capable of promoting assimilation in plants or decomposition of carbon dioxide and water. In 1889 and 1890 a series of very important experiments were conducted at the Agricultural Station of Cornell University to show:

1. That the electric light may be used under such conditions as to make it fairly comparable with sunlight in its power to promote protoplasmic activity.

2. That the electric light acts as a tonic to plants so that they are able to endure adverse conditions which otherwise would cause them to collapse.

3. That the electric light is a true vital stimulus, since the effect of its use at night upon plants is essentially the same as that of the longer day of the Arctic upon plants growing in those regions.

These observations agree with those of Siemens, made some years before, in which it was shown that a plant exposed to ordinary daylight and six hours of electric light in addition, "far surpassed the others in darkness of green and vigorous appearance generally." Strawberries and other fruits were fully equal to those raised under ordinary conditions, and grapes were of stronger flavor than usual. Melons were remarkably

large and aromatic, and bananas were pronounced by excellent judges to be "unsurpassed in flavor."

It has been known for many years that workmen engaged in electric-light plants, or otherwise exposed to the influence of powerful arc lights, sometimes suffer effects similar to those of sunstroke, showing that the electric light is capable of producing profound impressions upon the nervous system and the tissues of the body in general. It was a knowledge of these facts that led me to undertake investigations which finally resulted in the development of the electric-light bath. Having engaged in sanitarium work for more than a quarter of a century, in which time I constantly made use of the sun bath, as well as other modes of applying heat to the body, I thought

Fig. 1.—Upright cabinet for electric-light bath.

it worth while to make careful investigation of the value of the electric light as a source of thermic energy. I had constructed, as early as 1891, various experimental forms of baths which I have gradually perfected. Some of these admit the whole body in a sitting posture, others lying down. Some are adapted to the application of heat to a circumscribed portion of the body, as the trunk, the feet or the spine. The accompanying cuts show the several forms of bath that I have in use at the present time. These baths are now employed in various places in this country and in foreign lands.

The electric-light bath has been received into special favor in Germany. Professor Winternitz, the greatest living authority on hydrotherapy, speaks as follows respecting the electric-light bath in his re-

cently published treatise, "Physiologische der Hydrotherapie": "The electric-light bath is a method of recent origin and equal to the sun bath. It was at first employed empirically. (Only the arc light was thus employed, and in the most inefficient and unscientific manner.) Dr. Kellogg of Battle Creek has constructed one for the entire body, as well as for the separate parts thereof. Various shaped cabinets are supplied with mirrors internally and a great number of electric lights. In the center of a large cabinet is a chair upon which to place the patient; in a still larger cabinet an entire bed can be admitted with the patient in a lying position, thus enabling the light to be thrown on the entire body. In Germany one can see in certain places, Chemnitz (Dresden) instead of the small electric lights, arc lamps (carbon) without glass, placed in the corners of the large cabinet.

"It has been undoubtedly demonstrated that radiant heat penetrates the tissues much better than conducted heat, and it is quite probable that cellular activity is powerfully changed by these rays of heat (either qualitatively or quantitatively). The effects of the vapor bath can be brought about in the cabinet, and the differences thus far determined are the following: The giving off of the $C O_2$ is more abundant than in the vapor bath, and what is especially noteworthy is that the perspiration appears very soon and at a very low temperature, and is very profuse. We notice the earlier appearance at 95 degrees F. (Kellogg averaging 85 degrees F.), while in the vapor bath a much higher temperature is generally required to produce the same effect. The time at which the perspiration in the electric-light bath appears averaged three and one-fifth minutes, while

Fig. 2.—Horizontal cabinet for electric-light bath.

"As soon as the electric source is introduced the entire body is flooded by the light, the rays are constantly reflected by the mirrors so that the entire body is very uniformly and intensely illuminated.

"The temperature of the atmosphere in the cabinet varies according to the source of light, and is increased very much by the use of arc lamps (167 degrees F. and over), while by the use of the incandescent or glow light, a slow increase in temperature takes place, and hardly reaches the above-mentioned temperatures. The increase of temperature when globe lights are used may be easily influenced by introducing more or less lamps or globes which have a greater or less degree of exhaustion. Those lights which contain the greatest amount of air give more heat than those which have been more thoroughly exhausted. The effect upon the body is, as far as our limited observation goes, equal to that of a vapor bath, but differs materially from it.

in the vapor bath almost five minutes was required. Finally, the quantity of perspiration in the electric-light bath is considerably larger. That the rays of heat here play the most important part, and that it is not on account of the temperature of the air in the cabinet, is further shown, for instance, by the fact that the external surface of the thighs, which were directly opposed to the light, perspired much more rapidly and profusely than the inner surfaces which received only reflected rays. Within ten to thirty minutes the temperature reached 104 degrees F., pulse 160, respiration 42, with symptoms of fever-like condition. We have thus far employed the electric-light bath, like the vapor bath, only in a few disorders, such as chlorosis, chronic rheumatism and gout, and have obtained satisfactory results. More extensive experience is wanted. Kellogg reports very favorable results of treatment of chlorosis, gout and a number of cases in which there is need of increased

metabolism. Lahman reports regarding psoriasis:

"As we now possess a thermic method in the electric-light bath by means of which we are able to measure the exact dose, and knowing the power influence on cell-life and the entire organism, we believe this method of thermic application should receive an important place. It enables us to influence a number of maladies much more rapidly, better and more intensely than we have heretofore been able to do."

Fig. 6 represents the apparatus as used by Professor Winternitz. Several German manufacturers are making electric-light baths of different sorts, and the bath is rapidly gaining favor among German practitioners. I am sorry to say that in Germany it is also being exploited to a considerable extent by charlatans.

As stated in the paper above referred to, I believe that the peculiar value of the electric-light bath is due to its efficiency as a means of communicating heat to the body. In the Turkish bath, heat is communicated to the body chiefly by the convection of heat and air. Air, being a very poor conductor, communicates heat to the body very slowly. Absorption of heat is further hindered by the skin, an excellent non-conductor, and by the rapid evaporation of moist-

manner as it penetrates any other transparent or translucent medium. In case of the water bath, Turkish bath, vapor and hot-air baths, heat reaches the interior of the body by conduction, passing through successive layers of living tissue which, while affording great resistance to conduction of heat, readily allow the passage of the luminous rays from the incandescent film. It is true that non-luminous as well as luminous heat waves are thrown off by heated bodies, the whole gamut of radiant energy in the form of heat being stated to consist of fully four octaves, more than two of which are below the red, while a whole octave is above the violet, the luminous range occupying a space only a trifle greater than what would correspond to a chord of the sixth in music. But the lower octaves of these heat waves seem to be far less active than those included within the luminous area and above it. I do not consider that there is any specific effect obtainable from the electric light which would not be derived from any equally efficient source of radiant heat, and on this account I should prefer to use the term the *Radiant Heat Bath* rather than *Electric-Light Bath*, as the former term leaves room for the employment of any luminous source of heat

Fig. 3.—Electric-light spine bath.

Fig. 4.—Electric-light trunk bath.

ure upon the skin, whereby it is cooled so rapidly that it is possible for a man to enter and remain for a considerable time in an atmosphere far above the boiling point. I have several times been in a Turkish bath at 300 degrees and suffered no inconvenience. The heat derived from the electric light, however, enters the body by radiation and not by convection.

The skin, as well as the air, is to a large extent transparent to radiant heat, and the same is true of all the living tissues. This is evidenced by the phenomena of transillumination. By a speculum placed in the vagina or rectum, and a suitably arranged electric light of 16- or 32-candle power placed over the abdomen, one may see the interior of the pelvis illuminated and made to glow with a bright red light, the red color being due to reflection from the red corpuscles of the blood. Even the bones are transparent to light when in a living state. This is clearly shown by placing the hand between an electric light and the eye with the fingers in close contact. The hand being placed near enough to the light, the whole finger will be seen to be illuminated by the light and not simply the soft parts. Light penetrates the body in the same

which may possess properties identical with those of the electric light.

In the incandescent electric-light bath perspiration is induced at a temperature of 85 degrees F. The air about the patient is usually the same as the ordinary room temperature, while the Turkish bath requires 150 to 200 degrees F, and the Russian 120 to 140 degrees F. Pure air at ordinary temperature is provided for the patient in the electric-light bath, instead of the heated impure air of the Russian or Turkish bath. The electric-light bath does not depend upon the effect of the heated air surrounding the patient, as in the Russian or Turkish bath, but upon the radiant energy which passes in straight lines from the incandescent filament into the patient's body without heating the air, the air about the patient being of the ordinary temperature; just as a person standing in front of a log fire out-of-doors on a frosty night may expose one side of his body to intense heat, while the other is chilled by the zero atmosphere which surrounds him.

A score or more of these baths are now in use in this country and in different parts of foreign coun-

tries, and with these baths several hundred thousand applications have been made within the last few years, and the results have been such as show that it is destined to be permanently recognized as one of the most effective agencies for combating a large variety of morbid conditions.

In auto-intoxication the electric-light bath is particularly helpful, as it not only stimulates elimination through the skin, but by penetrating the tissues, stimulates the processes of oxidation whereby toxins and waste matters are prepared for elimination. By accomplishing the results required of it in so short a space of time the electric-light bath is comparatively free from the exhausting effects which often result from the Turkish bath, the hot immersion bath and other modes of inducing perspiration. In the treatment of the rheumatic diathesis there is no agent which so promptly affords relief as the electric-light bath, since it adds to the powerful eliminative effects of heat the soothing influence of light upon sore muscles and joints. In obesity, likewise, the electric-light bath proves a sovereign aid through the pene-

Fig. 5.—Electric-light trunk bath in use.

trating power of its rays, which stimulate the processes of disassimilation, while at the same time aiding the elimination of débris.

Nervous headache, or migraine, now pretty generally recognized as a toxemia, yields readily to the systematic employment of the electric-light bath in connection with the proper regulation of diet. The electric-light bath enjoys the great advantage over other methods of applying heat in that it produces strong atonic effects, at the same time that it encourages powerful elimination.

As a prophylactic, the electric-light bath possesses a high value, especially for persons who are compelled to lead a sedentary life, such as teachers, doctors, lawyers, preachers, judges and professional men generally, and to a still greater degree by the majority of women, and which necessarily results sooner or later in disease and premature death from the accumula-

tion within the body of those poisons which are destroyed or thrown off through active exercise in the open air. The electric-light bath is the best of all substitutes for muscular activity; for persons whose business necessarily keeps them confined indoors, it is the most invaluable means of maintaining sound health. The importance of skin activity as a means of maintaining health is intuitively recognized by the dwellers in the Arctic region. Every Laplander's house has a sweat-room connected with it, in which every member of the family takes a weekly sweat followed by a plunge into a snowbank during the cold and inactive season of the year.

In this country a vast number of people, especially dwellers in cities, are daily suffering from the deteriorating influence of a sedentary life, to whom the electric-light bath, combined with a cold shower bath,

Fig. 6.—Cabinet for electric bath (Winemitz).

would prove an inestimable boon. An especial advantage of the electric-light bath is the comparatively small cost of installation. The Turkish and Russian baths require expensive heating apparatus, furnace, steam boiler, in addition to fireman and engineer and frequent visits from plumber and steamfitter to keep everything in order. The electric-light bath is complete in itself, requiring no greater expense in installation than the running of two small wires for a short distance. The bath can be placed in the back room of an office, or, for private use, may be placed in a bedroom, or even in a bathroom. Another very great advantage is the small expense involved in the maintenance of the bath. After the bath has been installed and connected with the city current, the expense for maintenance is simply the cost of the current. This expense is incurred only while the bath is in actual operation, whereas the expense of the Turkish or

Russian bath is more or less continuous, as the bath must be held in constant readiness for use. The usual length of an electric-light bath is from two to ten minutes, according to the effects required, the average length being about five or six minutes. This would make the cost of a single bath $2\frac{1}{2}$ to 3 cents. There is practically no cost for repairs. There is nothing to wear out in the electric-light bath except the lamps, and these are guaranteed to last a thousand hours, which would furnish an electric-light bath every day for fifteen years. The electric-light bath is always ready for use. It is only necessary to turn on the current, and the light shines out instantly, and with its full intensity. Another touch of the button, and the heat is removed wholly or in part, as quickly as it came. Thus the heat may be instantly and perfectly modified to suit the requirements of each individual case.

By a number of simple appliances it is possible to localize the electric-light bath at will. For applying heat to circumscribed areas of the surface the electric light is superior to all other sources of heat. In use it is far more convenient than the fomentation, hot bags, or any similar appliance. I am sure that the radiant energy of the electric light penetrates the tissues to a depth of several inches. This I proved by actual observation, as before intimated. For deep-seated pain, as well as for the relief of hyperesthesias of the skin, I know of no remedy more valuable. Many applications of this sort have been made by myself and my colleagues, several thousand in all, and I have constant reason to be grateful for the acquisition of this therapeutic measure, and it has afforded relief to many cases which have stubbornly resisted all other therapeutic means which I have been able to employ.

After having employed this bath in several thousand cases I feel justified in urgently inviting the attention of the profession to test its value, and I feel sure that a study of its merits will lead to its practical application in the treatment of a great variety of chronic ailments, many of which so obstinately resist ordinary therapeutic measures.

AUTO-INFECTION AND PATHOGENIC PHYSIOLOGY.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY C. B. NEWTON, M.D.

STAFFORD SPRINGS, CONN.

The increasing knowledge of pathologic anatomy and pathogenic physiology tends to evolution in therapeutics affecting our remedial agents. We discover that they have more or less definite value; they have their rise and fall. The drug extolled today by high authority we find does not come up to the manifesto of the manufacturing chemist and may be obsolete tomorrow. When antifebrin was first introduced, a child was brought from New York City for treatment. Their physician had prescribed this drug in 2-grain doses, to be given every two hours if there should be a rise in temperature. After they had given it for a couple of days, the nurse noticed cyanosis and coldness of the extremities, with failing pulse. This fact was a valuable one to us. It is now found to have its effect as an antipyretic by depressing the heart, it has a directly paralyzing action upon the cardiac muscle.

There is evidence that toxicologic effects are less common after the use of acetanilid, which does not keep the temperature down quite so long as the other antipyretics. To guard against possible accident, strychnia or quinin act favorably with acetanilid, on similar principle that we combine morphia with atropia. When the hypodermic method of using morphia was introduced, there was much precaution used to avoid the introduction of air, which might act as an embolus and cause death, and also might have a toxic effect by way of excitation of the peripheral nerves. It is now found that these dangers do not exist. We have the history of a case of supposed admission of air hypodermically with morphia which was followed by immediate death, when this method was first used. It cast much discredit upon the experiment, though the patient would have died if it had been taken by way of the stomach, as a result of the disease for which it was given. Our pathologic studies have also caused the evolution of antiseptics. The time was when an unclean skin, foul air and environment were disregarded by the surgeon. Lister began the war against microbic dirt. The mercurio bichlorid had its rise as a germicide, but its fall was only in the matter of lesser strength. It was found to act as a poison when poured into the abdominal cavity of the strength of 1 to 1000—it was reduced to 1 to 5000 and 1 to 10,000. Carbolic water was used of a strength which acted as a toxic irritant upon the tissues. The room was misty with carbolic vapor from the steam atomizer; the operation was performed in its cloud with hands dripping in the supposed germicide. Then came the announcement that the spores of the germ the vapor was aimed at could not be killed with oil of vitriol or boiling water. Then came iodoform, its villainous mephitic odor lingering in the operating room with the persistence of Mary's little lamb. It is now found that a solution of sodium chlorid answers equally as well in washing the field of operation. Lawson Tait uses water drawn from the tap, with equal success. Absolute cleanliness is where we are today in the evolution of antiseptics. It is a satisfaction to know that in the evolution of the treatment of idiopathic diseases we have found a definite cause—a germ, a toxic ferment, the product of which acts as a specific poison, "touching the life of all the blood corruptibly." If the microscope does not reveal to us all the toxicoses of a large family of ailments, it is because of the difficulties of chemic and microscopic study, but which are being overcome, and knowing the conditions of their inner development, we shall be able to prevent their destructive work.

Of the remissions of fever, its limitations, its dangers and its recurrence as an autumnal fever has always been known; but in this generation we have the probable discovery of its cause and individuality. Previously treatment could only be directed to the symptoms instead of its causation. My personal observation has been that a typical case of typhoid fever as it appeared thirty years ago is now somewhat rare. Since malarial fever became prevalent the latter has greatly modified it, being more remittent, less frequent hemorrhages, greater range of temperature, less delirium; quinin acting favorably, while formerly in the typhoid was no well-marked remedial effect, even contraindicated except as a tonic at the close of the fever.

The Brandt treatment, or the hydropathic, calls for a bath every half-hour, fifteen minutes at a time, when the temperature is 101 or upward; tells the patient to

amuse himself by rubbing his skin. This will lower the surface heat, but there is objection to this course when the patient is much reduced in strength or when hemorrhage is likely to occur. In any case the application of water of a temperature most agreeable to the patient is always best in its effect. The most satisfactory way is to sponge the exposed body at shortest intervals, wetting only the invalid while comfortably at rest in bed; we have reduction of temperature and economy of strength which will be needed at the crisis.

The Woodbridge treatment, which has attracted much attention, is fully in accord with the fact of the presence of a toxic organism in the intestinal tract. The tablets contain some of the active antitoxins—hyd. chlor. mitis, guaiacol, menthol, thymol, eucalyptol, though the most active and safe one known—the bichlorid—he has omitted. The only trouble we ever have with this latter is when given in doses so large as to offend the stomach. The 1/100 grain is a better remedial dose than the 1/15 grain, quinia being almost a specific when the fever develops the periodic type. Thirty years ago, when the soldiers came home from the South they quickly recovered from the chills, for the malarial wave had not swept over the Eastern States. When, upon its later visitation as an epidemic, we had instead of a typhoid fever whose prominent feature was a continuous high temperature with only slight remissions at the end of each week for one long month, with delirium and hemorrhage, a new type whose greatest features were extremest cold, rapidly followed by extremest heat, then a diaphoresis unknown in other fevers. The popular theory is that all pathologic conditions have origin in bacilli from without. May not toxic organisms result primarily from decomposition of tissues, the warmth and moisture of the body becoming a medium, causing by their presence in the blood an auto-infection from the diseased organ, thus distinguishing from germ causing diseases? There is an old saying that "no man of himself doth catch." He may have antitoxins destructive of life which he can not transmit. He can contract pneumonia, not from others, but from well-known exposure to a rapidly alternating temperature and moisture, and the morbid opportunity of the winter cold. A suspected pneumococcus is discovered in the lung tissue after it has reached the morphologic change, the gray or yellow hepatization, the primary cause being a sudden suppression of normal perspiration and peripheral nerve excitation. It rarely occurs during the summer months, when the earth, the air and the turbid waters are swarming and humming with bacterial and insect life. Only the pneumo-germ is absent. By the skin, an important excretory and absorbing organ, is eliminated inorganic salts, carbonic acid, acetone, urea, alkaline lactates, and sudorates, which produce auto-inflammations when interrupted and reabsorbed. The water of perspiration contains these salts in perfect solution as impure water. Vital statistics show plainly the increase and subsidence of fevers and diarrheas of children during the cold and hot months.

In Hartford, in 1895, there was only one fatal case of typhoid fever in February, 3 in March, none in April, 7 in November and December. In January, 1896, no fatal case; in July, August and September 12 fatal cases were reported. For 1897, in March there were no fatal cases; in September and October 10 fatal cases. Statistics illustrate the influence of the

seasons in the mortality in that city of children under 5 years of age during the hot and cold months from diarrhea. In March and April, 1897, there were no deaths, but in the months of July and August 40 children died of this disease. In January, February, March and April, 1896, there were only 3 deaths, while during the months of July and August 52 deaths were reported. The greatest variations of thermometer, barometer and hygrometer are noticed in those States bordering on the Pacific and Atlantic coasts. Mark Twain once met a gentleman who told him he was making a collection of all the kinds of weather in the world, to have a museum of meteorology. Twain told him that traveling to extreme parts of the globe was useless; that if he would come East he could get all the kinds in a week.

We have 3000 miles of continent on one side and 3000 miles of ocean on the other, representing the extremes of dryness and humidity. From the far north we have its unvarying cold, from the south the hot breath of the tropics, the benign wind of the continent on the west and the sea-breeze of the Atlantic Ocean on the east. The summer months are the most gracious and lovely of the year. We are at peace with nature; even the ocean is pacific after the storms of winter. The charms and splendors of the year are now complete. That great meteorologic varieties increase the mortality, we recall the fatal influence of the blizzard of 1888, when the amount of sickness and number of deaths was enormous. Of a continuous and intensely high temperature, we recall the death-rate in New York City in 1896 during five days of phenomenal heat, from August 9 to August 14. It was estimated that 1000 persons died directly from its effect, that the deaths of as many more were caused by it among the infants and children from the intestinal antitoxins of cholera infantum. At St. Louis it proved as disastrous to life as did the great tornado, Cholera would not in the same time have caused so great destruction of life as did the sun heat. When the north wind came, invigorating with its ozone, the heated term was closed.

Am I speaking disrespectfully of the microbic family when I say that as an exterior bacterial cause they were not in it? They were surely at the demise of tissue and disposed of its remains. The question is: Were they present there as a primary cause, or was death the result of retrograde metamorphosis, the decay and dissolution of the organic tissues and of the blood from active hyperemia of the brain induced by the insupportable heat of the sun's rays?

According to the experiments of Professor Bouchard, the organism in its normal, as in its pathologic state, is a receptacle and a laboratory of poisons. Among these some are formed by the organism itself, others by bacterial proteids, low forms of vegetable growth which are the guests or the normal inhabitants of the intestinal tract, or are parasites at second-hand and disease-producing. Man in this way is constantly living under the chance of being poisoned. Yet this intoxication is not realized, for the organism possesses resources which enable him to escape. The carbonic acid which the lungs exhale in twenty-four hours, if a fractional part were retained, would act as a fatal poison.

The auto-intoxication caused by the presence of bile in the blood is a familiar illustration of the toxic symptoms of bile acids affecting the cardiac ganglia, as shown by the slowing of the pulse if unattended

with inflammation. There is languor and muscular weakness; he feels that he is being weighed down by some grave mistake that his liver has made, really from fault of habit or diet. As elimination is incessantly being effected through the kidneys, experience shows us that the most intense form of jaundice does not kill, because the coloring matter, which is more poisonous than the salts, escapes by way of the kidneys. As a result of absorption grave cerebral disturbances arise from its autotoxic effects, with delirium, convulsions and coma.

It is a reasonable conclusion that because of the waywardness of our organism, the diseases of auto-origin should be studied, as well as those of a more definite germinal character coming from without, it being the fate of our structure that many of the diseases to which flesh is heir are born within us.

COLORING MATTERS AND FERMENTS.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY J. F. PEAVY, M.D.

ASHEVILLE, N. C.

No other generalization which the human mind has reached has done so much to bind in organic unity the phenomena of the physical universe as the law of conservation and correlation of forces. It has helped very largely, too, to clear our thinking of many vague and unscientific notions. Among these is the notion of a vital principle or force. Science now substitutes the more definite and logical conception of organization, itself, accomplished through natural means, appropriating, co-ordinating and directing natural forces. In the light of this law, the phenomena of organic nature in their physical aspects become interpretable as incidents in the ceaseless redistributions of matter and motion, of which all organic changes consist. Vital changes are natural phenomena, and are linked in by physical bonds with the successions of nature. The forces through which life manifests itself are drawn from and returned to the common stock in nature.

The inorganic basis of organic development was laid during the variations of heat and pressure incident to the cooling and contraction of the earth. Under suitable temperature and pressure conditions, the so-called elements, as well as the higher inorganic compounds, as they exist in nature, have been formed and stored in the composition of the earth's crust and atmosphere. For ages the earth was thus engaged in fixing a large part of her own surplus energy under the form of balanced chemic attractions, transmuting the coarser irregular motion—heat—into the finer, systematized motions upon which depend the chemic properties of substances.

The properties of any substance, in the widest sense, may be defined as its stored potentiality of reacting in its own defined and characteristic way to incident forces. This potentiality inheres in the molecular constitution of the substance, and the definition is true of any aggregate of matter, be it molecule or man. Working with its own supply of force, our earth must have stopped short of organic evolution. It could never have produced the higher differentiations of form and function—the life and beauty of organic nature. A continued increment of energy is necessary with which to build organic properties or functions. This is furnished by the solar radia-

tion. In the organic world, the light, heat and chemic energy derived from the sun under the form of vibratory motion constitute the source of power-supply for building up the almost infinite number and variety of forms. On the other hand, the combining activity of oxygen, which, in organic nature is the complement and correlative of solar force, gives to these forms while living the capacity of vital expression, and finally restores them when dead to the condition of inorganic matter.

The three general functions of life, considered in its dynamic relations, are: the fixation or storage of solar energy; its redistribution and organization in securing organic balances, and its final liberation as vital, and for the most part, motor functions. The first of these functions is accomplished in the vegetal world through the agency of chlorophyl in the green portions of plants; the second is carried on in both vegetal and animal forms, through the instrumentality of ferments, acting as the agents of the cellular elements; while the final liberation of this stored solar energy is accomplished through the agency of hemoglobin (and its derivatives—the coloring matter of bile and urine) and transmuted into the distinctive activities of animal life.

In the economy of organic nature, chlorophyl; the green coloring matter of plants, and hemoglobin, the red coloring matter of blood, perform functions that are complementary to each other. They may be considered as placed at the two extremes of a series of chemic bodies, embracing between them the various catalytic agents active in living forms. The entire group exercises peculiar dynamic functions that are of the highest importance in the transformations of force effected by living organisms.

Chlorophyl is concerned in building up from inorganic materials, organic compounds utilizing and storing the energy of the solar rays, while hemoglobin is concerned in oxidizing these compounds and liberating the stored-up force. Chlorophyl stands at the base of the nutritive processes of vegetable life and maintains a port of entry for materials and force which build up the organic world, while hemoglobin actively supports the vital manifestations of animal life and, assisted by its derivatives, the coloring matters of bile and urine, restores to inorganic nature the materials and energy which have served their ends in the animal economy. Chlorophyl, by giving, as it were, specific direction to the vibrations which constitute solar light and heat tears asunder the atoms of carbon and oxygen in carbonic acid, CO_2 , and of hydrogen and oxygen in water, H_2O , freeing O, while the C and H are appropriated by the plant in the formation of carbohydrates and other oxidizable compounds, while hemoglobin supplies O, breaks up the oxidizable compounds and forms carbonic acid and water.

In order to further develop our theory and to furnish a basis for its postulates, it becomes necessary to introduce some general considerations relating to the properties or functions of matter, and especially those of the metal—iron. Electricity, magnetism and chemic activity are affections of matter having a common starting-point or basis in the capacity of matter for molecular polarization. They are convertible each into the other two. Electricity and magnetism might be called conjugate forces, so close and direct is their correlation. They are inseparably associated through acting in lines perpendicular to each other. To excite a molecule electrically is to excite it mag-

netically in a direction transverse to the line of electric excitation. To magnetize a molecule in a given direction is to electrize it in a transverse direction. Starting with this condition of molecular polarization, determining conditions decide what the resultant action shall be. If the proper conditions be present, the force propagates itself as electric currents. If answering chemic bonds are within reach of the excited affinities, chemic unions and rearrangements result. Should the conditions for conduction or chemic action be wanting, static electric conditions are established.

Most of the elements may be arranged into an electro-chemic series with the alkali metals—potassium, sodium, etc.—with hydrogen at the positive end, and the halogens—bromin, chlorin, etc.—with oxygen at the negative end. In the middle of the series are iron and manganese. These metals present a strong resemblance in the variety in color of their oxides and salts, their behavior toward oxygen, their magnetic properties, and the fact that they may occupy either the acid or the basic side of salts. From this last fact we infer that they are sometimes found on one side of the middle line manifesting acid or negative affinities, sometimes on the other, manifesting basic or positive affinities, their behavior depending upon special conditions in the different cases. It is by reason of their position in the electro-chemic series, possessing nearly balanced affinities in opposite directions, that the condition of bipolarity may be readily induced in them and they are hence distinctively magnetic.

The special office of magnetism in nature is to transmute other forces, to serve as a pivot or vehicle of change in their direction or modes of action. It is itself dynamic, that is, capable of producing effects, mechanical, electric or chemic, only when the body in which the magnetic condition exists or that upon which it acts is in a state of *motion*, or the magnetism itself is varying, commencing, increasing, diminishing or ceasing, in which case the molecules themselves may be inferred to be in a state of motion. A magnet is an aggregation of molecular magnets, and its action is the combined action of its molecular elements. A permanent magnet may be viewed as a static condition of force, of motion arrested and stored in the form of bipolar tensions. It embodies the capacity to take up mechanical motion and convert it into other modes of force. This capacity has been turned to immense practical account in the magneto-electric machinery so highly developed of late years. The capacity to transmute mechanical motion into electro-chemic force is possessed by each molecule of a substance in a condition of magnetic excitation. The aggregation of molecules into magnets simply aggregates or combines their action. With these facts and deductions from accepted facts before us we are now in position to further develop our theory or view of the action of these immensely important physiologic agents.

The coloring matters, chlorophyl and hemoglobin, contain the magnetic metal, iron, and upon this primary property of iron depend their peculiar dynamic functions. True, there is a striking contrast in the manner in which the property comes into play in the two cases, being made the basis of a function in each which undoes what the other does. This contrast will appear as we proceed. The action of chlorophyl is a dynamolytic process comparable to electrolysis; in fact, virtually the same. The iron of chlorophyl is

magnetized and set in motion by the energy of the solar rays. Thus are developed what are essentially rotating magnets. The condition of magnetization and correlated electro-chemic excitement with rotary motion in the atoms or particles of iron is a transitional condition of the force, which, received on the one hand as vibratory motion, is delivered on the other as electro-chemic force. This electro-chemic force is expended in tearing apart the atoms of C and O in CO_2 and of H and O in H_2O , and become posited, as it were, in the atoms of O on the one hand, and of C and H on the other, to be again delivered up as heat, mechanic motion, or muscular and other forms of vital activity when these atoms again meet at the other border of the organic world. This attractive force of the atoms of H and C on the hydrocarbonaceous compounds formed for the C which has been removed and diffused in the atmosphere, is the exact equivalent of the solar energy used in parting them, and constitutes the ultimate basis of all force manifestation in organic nature.

Plants utilizing the energy of solar light and heat, manufacture, out of materials drawn from the atmosphere and taken up from the soil by the roots, a variety of compounds—starch, fats, albumin, etc. A part of these compounds fall from the elevated plane of "proximate principles" to the condition of simple binary compounds, the measure of which retrograde metamorphosis is the amount of CO_2 exhaled by the plants. The descent from a higher to a lower plane liberates force, which, in conjunction, perhaps, with heat derived from external sources, and, acting through the agency of diastase and other so-called catalytic agents lifts another part of these compounds to the grade of organized vegetable tissue. The greater part, however, remains as reserve stores of material and force to be either used by the plant itself in the formation of parts subsequently developed, or to serve as food for animals.

Animals receive, ready prepared for them in the vegetable kingdom, the material for their nutrition and structure embodying the capacities for the force evolutions which constitute the expressions of life. True, much of this material is raised to higher planes, substances of exceeding complexity, of high molecular weight, being required to meet the demands of the extreme differentiation of form and function in the higher orders of animal life. In this lifting of pabulum for the formation and maintenance of organic structure, force is consumed, contributed no doubt by the retrograde metamorphosis of other constituents of the food, but rendered available through the agency of so-called ferments. Some of these are, in all probability, products of the ductless glands and as yet but little known. The great and striking characteristic, however, of animal as distinguished from vegetable life, lies in the fact that its chemic processes are, in the main, reductions of matter with evolutions of force which find expression as heat, sensori-motor activity, etc. At the top of the scale of organic nature, we find beginning processes the exact reverse and complements of those we found initiated by solar energy through the agency of chlorophyl in the green leaves of plants. These processes end in the complete restoration to inorganic nature of the matter and forces which have performed their parts in the mystic play of that inscrutable something we call life.

The red corpuscles of the blood, by virtue of the iron which exists in them as a constituent of their

hemoglobin, take up oxygen from the air in the lungs and deliver it up in the capillary circulation, returning with their hemoglobin in the reduced condition. In making the circuit from the lungs, through the capillaries and back to the lungs, the hemoglobin changes from the bright red of highest oxygenation to the violet of lowest reduction, passing, no doubt, through the whole gamut of colors. When it leaves the lungs it occupies the red or dynamic end; when it returns to the lungs, the violet or chemic end of the chromatic scale, its color at each stage of the declension being the index to its dynamic capacity. At the point of lowest reduction its dynamic capacity is a minimum, its chemic affinity for oxygen after it reaches the lungs, a maximum. At the point of highest oxygenation, its chemic affinity is satisfied, its dynamic capacity a maximum. In the capillary circulation this chemico-dynamic force—of which hemoglobin in its transit from the lungs is the vehicle—is reconverted into heat and motion by the impact, as it were, of atoms which had been torn apart by the dynamolytic action of chlorophyl in the green leaves of plants.

Chlorophyl and hemoglobin, with the other catalytic agents between them, require for their physiologic activity certain necessary conditions. One of these is always heat or other available force in the ascending, constructive, lifting, force-consuming series on the one hand, another the presence of oxygen with its capacity of unlocking force in the descending, destructive, force-releasing series on the other. Solar energy, either as the direct rays of the sun or as diffused daylight, is necessary, furnishing as it does the working force for the activity of chlorophyl. This activity, with the processes which depend upon it, ceases in the dark.

The permanent withdrawal of light starves green-leaved plants to death. True, it has been shown that plants will flourish in the electric light with the exclusion of the sun's rays, but the electric light furnishes energy under the form of vibratory motion practically identical in character with solar light. Diastase, which initiates and helps to carry forward the process of germination in seeds, is inert until supplied with the proper degree of heat. The same thing can with safety be affirmed of other agents related to diastase and concerned like it in constructive metabolism.

The nature and mode of operation of the various substances which serve to transmute heat into constructive energy under the directive agency of animal and vegetable organisms appear to me to furnish a rich field for practical investigation. The alkalinity of the blood and tissues furnishes an all-important condition for hemoglobin in the animal economy. The alkalinity of the blood differs in degree at the two extremities of the circuit. In the lungs it reaches its highest degree from the exhalation of carbonic acid. In the capillary circulation it becomes less alkaline from its absorption of the products of oxidation. In passing from the lungs to the capillaries the iron of hemoglobin crosses its equator between acid and basic affinities. In returning to the lungs it recrosses to its region of positive attractions. In the lungs it is electro-positive, and unites with oxygen, which is electro-negative. In the capillaries of the various organs and tissues of the body it becomes electro-negative, repelling its oxygen. The oxygen itself is doubtless converted into its allotropic form, ozone; that is, the atoms of O_2 , the ordinary condition

of oxygen, are dissociated and polarized in the same direction. In this condition they can not unite with each other, but possess in the highest degree the affinities of oxygen.

In discussing the action of chlorophyl we figured the iron as in a condition of balanced bipolar tension, performing the part of rotating magnets, appropriating the solar radiation and converting it into electro-chemic force, thereby tearing apart the atoms of O and C in CO_2 and of H and O in H_2O and positing the energy of O, on the one hand, and of C and H on the other, under the form of chemic affinity. In the case of hemoglobin, we view the iron as oscillating between acid and basic affinities, being in the one case, in the condition of electro-positive accentuation, uniting in the lungs with the electro-negative oxygen; while in the other case, through a change of chemic environment, it swings into the opposite direction of electro-negative accentuation, throwing off the electro-negative oxygen, the resulting oxidation reconverts the chemic affinity into heat and other forms of energy. It would seem, however, that the alkalinity of the blood, with its changes in degree at the extremes of the circuit, does not absolutely endow hemoglobin with its polarity or cause of itself alone the reversals of affinities. Blood outside the body will for a time manifest this property, as shown by its changes in color from red to purple, or from purple to red, according as the oxygen is excluded or supplied. Hemoglobin, if extracted unchanged from fresh blood, will behave in the same peculiar way toward oxygen. Even the hematin in blood-stains possesses a remnant of this property. An examination into the *rationale* of the guaiacum test for blood discloses this fact. Peroxid of hydrogen does not by itself oxidize a solution of guaiacum, producing the characteristic blue reaction, because its loosely-held oxygen is liberated in the condition of antiozone, and only agents liberating oxygen in the opposite or ozonic condition can produce the reaction. If hematin be present, however, the reaction occurs, the antiozone undergoing a conversion into ozone. This seems to indicate that the iron, retaining something of its physiologic setting in the hematin molecule, retains also something of its physiologic power.

The alkalinity of the blood, however, with its changes in degree at the extremes of the circuit is necessary to the performance of the physiologic function of the red corpuscles by determining the time and place at which the reversals of the oxygen affinities of hemoglobin occur. In the lungs, where alone oxygen is obtainable, the highest oxygen affinity of hemoglobin is thereby developed. In the capillaries of the various organs and tissues of the body, where oxygen is needed to meet the demands of the ceaseless change, the highest repulsive force of hemoglobin for oxygen is thus brought into action. When the blood-cells die, their hemoglobin undergoes a conversion into a substance which has been called "hematoidin," the more complex molecule of the former breaking up and the atoms of C, H, N and O rearranging themselves into the simpler molecules of the latter. This substance is believed to be identical with bilirubin, the yellow-red coloring matter of bile. The transformation of hemoglobin into bilirubin appears to be a spontaneous change, taking place under the conditions furnished in the blood of the living animal when the blood-cells die.

Bilirubin has been found in old extravasations of

blood, evidently produced upon the spot by transformation of hemoglobin. If red-blood cells be broken up and made to assume a liquid form by alternate freezing and thawing, and the solution be injected into the veins of an animal, the operation is followed by a discharge of bilirubin in the urine. Under ordinary conditions, the liver extracts the coloring matter from the blood-cells as fast as they die, completing their disintegration. Under certain abnormal conditions the liver is unable to keep up with the work of removing the disengaged and transformed coloring matter, and jaundice supervenes. Probably most forms of hematogenous jaundice are due to unusual or rapid death of blood-cells, either from direct poisoning or depraved nutrition and consequent excessive liberation and transformation of coloring matter. Here the liver, though acting perhaps with its ordinary capacity, is incompetent to rid the system of the excess.

If the disorganization of the blood is very rapid or profound, such grave conditions as hemorrhage, ecchymoses, hematuria or hemoglobinuria develop. Various toxic agents may interfere directly with the activity of the liver-cells and lead to abnormal retention of coloring matter. Probably the jaundice which follows phosphorus poisoning is the joint result of rapid destruction of blood-cells and direct toxic action on the cells of the liver. The moderate jaundice, which usually exists in connection with cirrhosis of the liver, is due to the incapacity of that organ, from pressure on its cells and diminished blood-supply, to remove the coloring matter with sufficient rapidity, though the death-rate among the cells may be only ordinary. Here, however, the increased discharge by the kidneys compensates in a measure for this impaired function of the liver, and the jaundice is not apt to be marked. Jaundice from catarrh of the bile-ducts or other obstructive conditions has for us no special interest in this connection. The coloring matter of bile as a physiologic agent occupies a place between the red coloring matter of blood and the green coloring matter of plants, and performs functions related to that of each, taking part in the vegetative processes of nutrition on the one hand, and the oxidations of animal life on the other. It is a fact, too, worthy of note, that the chemic and spectroscopic properties of this substance indicate very interesting and significant relations to hemoglobin on the one side and chlorophyll on the other. It exists in *two conditions*—bilirubin and biliverdin, the red and the green matter of bile. The difference between them is one of hydration and oxygenation, biliverdin being derived from bilirubin by the assumption of a molecule of water and an extra atom of oxygen, thus:

Bilirubin is formed from biliverdin by reversing the process.

Permit me at this point to state some facts which are considered settled by experimental evidence. Bile drawn directly from the bile-ducts during digestion and absorption is green, its coloring matter being in the condition of biliverdin. Bile obtained during the interval of digestion, or which has been stored in the gall-bladder, is yellowish red, its coloring matter being in the condition of bilirubin. If yellowish red bile be shaken up with air or exposed to the action of an oxidizing agent, as nitric acid or iodine, the color

changes to green; then, if oxygen be excluded by placing it in a bottle and corking tightly, the color changes to yellowish red again. This fact suggests an analogy to oxyhemoglobin and reduced hemoglobin.

Glucose, $\text{C}_6\text{H}_{12}\text{O}_6$, the product of the digestion of starch and saccharine substances, is deposited in the liver as glycogen or liver starch, $\text{C}_6\text{H}_{10}\text{O}_5$, undergoing a dehydration. After digestion and absorption have been completed, this material is given off as required by the needs of the system, undergoing a rehydration into glucose. There is reason to believe that albuminose—the product of the digestion of the albuminous elements of the food—undergoes a reduction in the liver to blood albumin, losing an atom of oxygen. We have already found reason to conclude that the conversion of hemoglobin into bilirubin is the normal transformation which follows upon the decay of the blood-cells under the conditions furnished in the circulating blood.

With these facts before us we venture to suggest further that, while digestion and absorption are in progress, the liver-cells, by a selective action upon the coloring matter of worn-out corpuscles on the one hand, and the glucose and albuminose of the portal vein upon the other, bring these substances into intimate relations with each other, effecting the interchange between them of water and oxygen, converting glucose into glycogen, albuminose into blood albumin, bilirubin into biliverdin. The green bile formed under these conditions is conveyed directly into the alimentary canal, and doubtless takes part in the hydrations and oxidations going on there. Having required these important and onerous duties of the coloring matter of bile, it might be suggested that we desist from further impositions. However, there are facts still unexplained, conditions unsatisfied, in our problem. The facility with which the bile coloring matter, chameleon-like, changes its hue, makes it a very accommodating substance. The secretion of bile continues during the intervals of digestion. A small reserve is stored in the gall-bladder, but the greater part finds its way into the intestine. Its color is now yellow-red, the conditions for forming green bile having ceased with the completion of digestion and absorption. The conditions in fact are reversed. Glucose, while undergoing deposition in the liver, required to be dehydrated into glycogen. In order to be available for the needs of the organism, it must be rehydrated and rendered again diffusible. The necessities of the case require us to lay this duty too upon the accommodating coloring matter. During the intervals of digestion yellow-red bile continues to find its way into the empty intestine, and is for the most part reabsorbed. In the portal vein the conditions are now present for the immediate conversion of bilirubin into biliverdin. We have already noted that if bilirubin in alkaline solution be shaken up with oxygen or atmospheric air, it is converted into biliverdin. Equivalent conditions are present in the radicles of the portal vein, that is, the blood is an alkaline menstruum and the hemoglobin of the red corpuscles is liberating oxygen. It is, I think, a reasonable assumption that the blood should carry some surplus of oxygen through the absorbent villi, during the intervals of digestion, since during the height of physiologic activity large quantities must be needed to meet the demand. Having the oxygen at hand, the bilirubin appropriates water from its solvent, just

as it does when shaken up in alkaline solution, with oxygen or air. In this way it is changed into biliverdin. Now, re-entering the liver, it comes in relation with the glycogen and yields up to it its water, becoming reconverted into bilirubin and reconverts glycogen into glucose. The atom of oxygen associated with the molecule of water, and liberated with it, is no doubt applied to the final oxidation of nitrogenous bodies which have served their ends in the economy. Of this reaction the urea formed in the liver is the product. The liver may be regarded as a chemico-vital laboratory in which certain elements of the food are prepared for assimilation; while others which have yielded up their capacity for meeting the demands of structure and function are prepared for elimination. The coloring matter serves the liver-cells in effecting these transformations by acting as a carrier of water and oxygen.

All honor to the men who are devoting themselves to arduous experimental work. Yet it is as much legitimate scientific progress to deduce the meaning of a fact as it is to get the fact. It is believed that the view presented in this paper is logical, consistent and true, resting upon a basis of accepted science. As an interpretation, then, of facts reached—to be sure, through the labors of others—it is hoped that it presents claims worthy of consideration.

DISCUSSION.

Dr. PEAVY—In closing this discussion I have nothing to add directly to the material contained in the paper itself. I am glad that Dr. Van Zandt has referred to the fact that hitherto no satisfactory explanation has been proposed of the mechanism by which the chlorophyll-bearing cells of plants decompose carbon dioxide and water, nor of the *rationale* of the oxygen-carrying and distributing function of the red-blood cells. These very difficulties first led to the investigations which resulted in the development of the view here presented. That the solutions offered are the true ones, my own mind no longer entertains a doubt.

In the decompositions effected by light in the green leaves of plants we have no more disturbance of unstable chemical balances, but the dissolution by a definite mechanism of the firmest chemical bonds. That the energy expended in effecting these decompositions is derived from the sun's rays, and is represented in the attraction of the divorced atoms for each other, is entirely beyond question. The process is clearly a conversion of mechanical into chemical energy. The postulate that this conversion and electro-chemical decomposition are accomplished through magnetization of the iron contained in the vegetal cells appears not only fully warranted by the premises adduced in the body of the paper, but it seems to be the only possible mechanism of the process. The facts of electrolytic decomposition and of the magneto-electric conversion of energy appear of themselves sufficient to render the conclusion necessary.

The theory that the oxygen-carrying and distributing capacity of hemoglobin is dependent upon a property of its iron, allowing it to exercise either positive or negative affinities under different conditions, appears also to satisfy the logical demands of the problem, and be fully justified by the facts of physics, chemistry and physiology. In proposing this explanation we are assuming no new property for iron. That it does manifest sometimes acid and sometimes basic proclivities is a well established fact. Its behavior in this regard is determined by its chemical environment.

Manganese, so closely related to iron in the electro-chemical position and properties, shares with it this oxygen-carrying function in the blood. The so-called catalytic action of black oxide of manganese, as illustrated in laboratory experiments, but shows the capacity of this substance under molecular agitation—heat—to take on and give off oxygen. Indeed, in certain chemical reactions manganese salts play the part of intermediary bodies, acting as carriers of oxygen, taking it from one and giving it to another of two bodies without being themselves directly affected in the reaction.

Blood outside the body, as long as it retains its vitality, will turn purple if oxygen be excluded, and then red again if oxygen be supplied. This shows that even without the special conditions furnished in the circulating blood, hemoglobin,

the color of which depends upon its degree of oxygenation, tends spontaneously to take on oxygen, liberate it and renew its supply. As far as this part of our theory is concerned, the proof amounts to scarcely less than practical demonstration.

Dr. Van Zant might have added that physiologists have never hitherto furnished the bile with a function in keeping with the quantity and constancy of this secretion. Doubtless it performs some secondary part in intestinal digestion—the green bile formed during the progress of digestion and absorption taking part, it may be in the hydrations and oxidations going on in the alimentary canal at that time. Intestinal digestion, however, is fairly well performed without the presence of bile, so we conclude that it is not primarily a digestive secretion. That it is not an excrementitious product is evident from its reabsorption from the intestine during the intervals of digestion. If the bile flow of the dog be diverted from the alimentary canal and discharged externally through a fistula, it is found that, while the appetite remains good and digestion is well performed, the animal soon begins to waste and finally dies from disordered nutrition. A significant fact is that the bile flow itself rapidly diminishes in quantity and becomes very scant. From this experiment we conclude that the bile is essential in some way to the nutrition of the body, and that its partial reabsorption is necessary to furnish part of the materials for continued secretion. So we seem forced to the conclusion that bile performs its most important function in the liver itself, and that even after it reaches the intestine in the intervals of digestion, it has not yet consummated its work. Whether the task I laid for it will meet with approval of physiologists generally remains to be seen. I wish to disclaim any intention of arrogating to the coloring matter the whole function of the bile. Only such part of it as is specially fitted by nature to perform and which is in general line with the work of this class of physiologic agents do I claim for its own specific function.

METHOD OF TEACHING MATERIA MEDICA.

WITH SPECIAL REFERENCE TO DENTAL STUDENTS.

Presented to the Section on Stomatology, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY WARREN B. HILL, M.D.

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, MILWAUKEE MEDICAL COLLEGE.
MILWAUKEE, WIS.

This subject, like many others, has two aspects: the real and the ideal. Dentistry is in a transition period. Some years ago it was almost a mechanical art, but there have always been in the profession men who held high ideals, and through their earnestness, enthusiasm and work it is being rapidly transformed into an ideal profession. In its highest sense dentistry should be, and is, a specialism in medicine, and the work of a number of men in this country has demonstrated that the best results and greatest achievements may be derived by making it so.

There is a tendency in the civilized world toward specialization. It has been found that higher attainments can thus be reached. But on the other hand, through narrowing the field of work, we are apt to contract the mind, and thus we find that which we gain in skill compensated by a loss in broader comprehension. It becomes necessary, therefore, when training a mind for specialty work, that we have a broad foundation upon which to build. It is not sufficient that one entering the study of dentistry should have acquired a certain amount of knowledge of English, mathematics and physics, but his mind should have been trained in broader fields, so that the concentration upon this single study will not have the effect of dwarfing the intellect and narrowing the mind.

The fundamentals of medicine should have been mastered early in his dental study, and his mind have been trained in grappling with the more abstruse problems in medicine, before he is obliged to concen-

trate his entire attention upon a portion of the oral cavity. I believe this proposition to be true from the standpoint of an educator, whose business it is to build up and round off a symmetric mind and character, and I believe it is also true from the standpoint of the practitioner, who, to be successful, must be familiar with all the factors that bear more or less remotely upon the conditions which he is treating. Thus, if we could teach dentistry according to this ideal, the question, "How much materia medica shall we teach?" would be answered thus: "All that is taught in the study of medicine." However, the obstacles that present themselves are a lack of time in the curriculum and a lack of disposition on the part of the student.

In a three-year course of six or seven months each year the average dental student is overworked in mastering the fundamentals of dentistry and medicine, and in doing the amount of laboratory and infirmary work necessary to make him proficient. It has become necessary, therefore, to abridge the work in materia medica, as well as in anatomy and physiology, in order that they may have sufficient time for the dental laboratory. In our institution there are some who are better endowed by nature, and who have a higher ambition than the average student. Realizing the advantages that present themselves by attending a school where both medicine and dentistry are taught, they are taking the full course in materia medica, therapeutics, anatomy, etc., thus completing, in a large measure, the fundamental work in medicine, in the anticipation of earning a medical degree, as well as that of D.D.S., in order that they may be better equipped for their practice, and at the same time they are rounding out their education and giving their minds a broader development.

For the average student the number of remedies in materia medica must necessarily be limited. The escharotics, the antiseptics and those that are used particularly in their everyday practice must have precedence, but there are many others whose actions have a remote influence upon the mouth and its diseases, which must also be taught. All of those affecting nutrition and assimilation have a direct interest to the dentist, and the art of prescribing should not be neglected, as it sometimes is. Having selected the few remedies we wish to teach, what to teach about them should be our next concern. All that we know is hardly too much. Their pharmacology is essential, their constituents and chemistry should be taught, and their physiologic action in its broadest sense should not be neglected, and then their therapeutic value in dentistry, as well as in medicine, should be the cap-sheaf of our investigation.

The question of how we shall teach it is a much more difficult one. Teachers are born, not made, and each teacher must adopt a method adapted to himself. In my work I have found the pharmacology of a drug can best be taught by object-lesson. The laboratory may be provided or improvised; it is only necessary that the student shall have an actual living acquaintance with the drug. The physiologic and therapeutic action can best be taught by didactic lectures, wherein the student may partake of the enthusiasm of his teacher, and may be made to feel, through that enthusiasm, the effects on long and personal experience with the remedy, which will inspire him with confidence—a mighty adjuvant in the application of drugs. There is much, however, that should be eliminated

from our lectures. The names, preparations, composition, chemic reaction, doses, etc., should be supplied in advance, that the student may commit them to memory, and have regular recitations and drill on them. This work should precede, or go hand in hand with, the laboratory work. I have never found a text-book which taught just what I wished to teach of any particular drug, nor one which treated only of those drugs which I esteemed of greatest importance to the student. I, therefore, have adopted a system of preparing skeleton notes which embrace those things that the student must commit to memory, furnishing mimeograph copies to each of the students, and leave for my didactic lectures that which I feel I could enliven by my personality. I have followed this course for three years, and the increased proficiency of the classes since its adoption has demonstrated to me the efficacy of the plan.

Having familiarized himself with the pharmacology of a drug, the student now comes to the most interesting part of his study. He has been grounded in his physiology, his chemistry, and his pathology, and now he is enabled to see the practical applicability of this knowledge in the application of the remedies to diseases. After due consideration, I have omitted to place upon my skeleton notes anything of the physiologic action or therapeutics of a drug, because they are not to be memorized, but to be reasoned out. Just how a drug acts primarily upon one organ, and through some of the great systems of the body results in a secondary action upon another organ, and drawing the parallelisms between the action of remedies and the pathologic conditions in diseases is as fascinating a study to the student in medicine or dentistry as is the illustrating of a natural law in physics. This is the logic of medicine.

In teaching therapeutics it is not sufficient to tell what diseases may be cured, and which harmed by the administration of a given drug. It makes a fascinating study for a student to take a disease, hunt out its etiology, trace the pathologic changes that take place, for the purpose of selecting a remedy that will overcome the conditions known to be present, eradicate the etiologic factor, or to build up certain structures in order to offset the destructive processes of the disease.

In my work this is still further supplemented by a course of applied therapeutics, in which we have the patient before us. We now can no longer follow the classic lines laid down in books, but must take diseases as find them, modified by the various agencies that environ the human animal. The pathologic conditions must here be studied out and remedies found that will logically supply the indications. If, perchance, in this course the student has witnessed diseases treated which are of little interest to him as far as he is concerned in his practice, he may have been given a lesson in mind culture that will serve him in good stead. The power of reasoning from effect to cause, and back to effect, is the best mental discipline for cultivating practical minds.

Potion for Whooping-Cough (L. Concetti).—Resorcin 2 gm.; antipyrin 1 gm.; aq. dest. 70 gm.; syrup of codein 10 gm.; syrup of cedar 20 gm.; tincture of opium 3 drops; tincture of belladonna 8 drops. A teaspoonful every hour or second hour to infants; a dessert-spoonful for children from one to three; and a tablespoonful for children over three.—*Semaine Méd.*, November 30.

NOISE AS A FACTOR IN THE CAUSATION OF DISEASE.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY ROBERT W. HASTINGS, A.M., M.D.

BROOKLINE, MASS.

Modern life has many peculiarities, and in his consideration of the influences which tend to the health or disease of the people, the physician must study carefully these features which may or may not introduce new factors. Among them, none is more frequently quoted than the tendency to group in large cities. So well accepted is this tendency that we need not give any figures to support the statement.

Many grave hygienic problems have resulted from this congestion of human life. Their solution has called for the most exact scientific research, careful formulation of sanitary laws and rigid enforcement of them. As a result, the dreadful scourges and epidemics which so often decimate the cities of the old world, do not obtain a foothold among us. Yet, disease is by no means abolished, though the average life may be a little lengthened. All too frequently life is cut short from preventable causes, and almost invariably one or more senses or faculties are impaired early in life. I ask your attention to one of the more obscure factors in the causation of disease which remains and in some lines is on the increase. Of scientific research in regard to it there has been very little. The reasons for this will be obvious. Still less attention has been paid to legal restrictions because of it.

What is noise? It is difficult to sharply separate "noise" from "sound." Ganot says: "Sound is the peculiar sensation excited in the organ of hearing by the vibratory motion of bodies, when the motion is transmitted to the ear through the elastic medium." "Sound, properly so called, or musical sound, is that which produces a continuous sensation, and the musical value of which can be estimated, while noise is either a sound of too short duration, like the report of a cannon, or else it is a confused mixture of many discordant sounds like the rolling of thunder or the noise of the waves." Whoever has lived beside streets can give better illustrations than these; for instance, the passing of a heavy team loaded with street-railway iron, or of a series of teams loaded with stone or coal. To such an one the "rolling of thunder" or the "noise of the waves" is like music. Now I do not suppose any one will deny that city life has in it far more kinds of noise than country life—not more sounds but more noises. And these noises are intensified and repeated by the high walls against which they strike and from which they rebound again and again. Nor are the street noises by any means all of the story. It is an unusual thing to be able to converse easily in any large factory. The persistent clatter, clatter of the machinery drowns the human voice almost completely. It is not the sound of the shoemaker, spinner, weaver or blacksmith in his or her country shop, but the confusion of a score or hundred similar sounds joined to a multitude of others made necessary by the machines and shafting.

Our consideration of what has been and is the effect of this noise incident to the great change in manner of life, naturally divides into three portions: 1, the effect of noise on the ear itself; 2, the effect on previously known or existing diseases; 3, its power to

originate disease or in any way affect the health of the general community.

With reference to the first, some careful observations have been made, for there is one class of men who work in the midst of such din that the attention of artists has been drawn to them. These are the boiler-makers. The constant reverberation of sounds produced by hammering large pieces of iron in a short time produces boiler-makers' deafness. St. John Roosa says, "boiler-makers are nearly all hard of hearing." "Those who work on the inside of boilers as riveters and who have shorter waves of sound striking upon their ears, lose their hearing most completely." Just what the lesion is, is not wholly decided. The author above cited thinks it is a hyperemia of the ultimate nerve fibers of the cochlea, and declares that "an acoustic neuritis may be produced by noise just as well as an optic neuritis by exposure to a glare." Dr. E. E. Holt records observations of deafness in boiler-makers, ship-caulkers, etc., but thinks the lesion is a middle-ear catarrh.

Dr. Roosa's theory seems to us more reasonable, however. Indeed, he has found that people with chronic middle-ear trouble hear better in the boiler factory, and ascribes this to the unusual excitation of the nerve. Doubtless many of you could give testimony of cases where deafness has arisen in persons exposed to constant loud noise. Boiler-makers and ship-caulkers are by no means the only ones who work in the midst of a din. The observations above noted are good as far as they go, but there is room for far more study in this line. This investigation, in order to be of value, must be carried on by experts who shall be able to separate results produced by noise from those due to other causes.

If we turn to the second division of our subject we find even less scientific research, but a general unanimity of professional opinion. When once it becomes evident that a patient is to be seriously ill, almost the first requisite is a quiet room. Thus Billroth advises for feverish and nervous patients a room where such noises as hammering, rattling of carriages, etc., can not be heard. Wise directs the selection of a sick-room on the second story, or higher in cities, and where it may be as quiet as possible. Many other authors might be quoted, but we all believe in it. When a patient—old, young or middle-aged—is sick, we want him in a quiet place. Now, why? What effect does noise have? Perhaps the chief result of noise is to prevent sleep, and sleep is an absolute necessity to bodily or mental recuperation. Indeed, Menander has said that all diseases are curable by sleep. We do not believe that, but we do realize its great value as a remedial agent. During sleep the brain becomes anemic, and the vessels of the skin dilate. Experiment has shown, too, that every sudden noise causes an increase of the volume of the brain, even though the sleeper is not awakened. Each such change produces a corresponding effect upon the nerve-centers and checks or prevents the processes of plastic nutrition. Thus, though the patient may become accustomed to the noise, the evil effect will be present to a greater or less extent. Quiet is desirable and may be necessary, not only as a means to secure sleep but to allow rest. When the blood-vessels are being continually contracted and relaxed according as the reflex centers are excited by noises or not, the disturbance in the supply of food to the diseased part is of grave importance. A

vicious circle is soon easily established, and the noise which at first seemed such a little factor becomes a very large one.

Suppose the patient *does* get a fair allowance of quiet sleep, if the other part of the day is disturbed by various noises, the course of the disease is thereby aggravated. The prevention of the ringing of neighboring church bells or of loud traffic along the street when a great statesman is ill, are familiar illustrations of the popular recognition of the desirability of quiet for sick people; it is just as desirable for any poor or obscure patient.

All this is true of any acute systemic disease. If, now, we turn to the chronic diseases or to those which have to do chiefly with the nerves or the great nerve-centers, we find our factor even more important. Details are unnecessary. Every physician knows the effect—sometimes fatal—of a sudden fright upon a chronic heart case, and a fright is as likely to come from a noise as from anything. Every physician knows, too, the steady failure of a nervous case, due to the constant repeating of noises about the patient. Between these two extremes we may find nearly every diseased condition of men—digestive, circulatory, nervous or local—each showing an aggravation if exposed to noise.

But does noise originate any diseases itself, and what effect, if any, does it have upon the general health of the community? We have already mentioned the diseases of the ear. Manifestly, as has already been indicated, contagious diseases can only be affected secondarily. Scientific research may yet discover, however, that sound-waves, like light-waves, do have a direct influence upon the growth of germs. It is difficult to see how any direct etiologic relation between noise and disease of the respiratory system can be traced. The same may be said of the circulatory, renal and digestive systems. Diseases of any of these portions of the body may, however, be secondary to nervous diseases. But does noise really cause any disease of the nervous system? Tyson describes nearly one hundred and fifty different forms of nervous disease, but to no one of them does he assign noise as a cause, with the possible exception of epilepsy, hysteria and neurasthenia. An epileptic convulsion or a hysteric attack may be due to a sudden fright, and this is likely to arise from an unusual noise. Neurasthenia takes its origin in the constant excitation and consequent exhaustion of the nerve-centers. Dr. F. X. Dercum has very successfully demonstrated this explanation of neurasthenia. No excitant is more frequent, none more persistent than noise. Moreover, so common is this disease in our country that it has aptly been called "Americanitis." Chapin says "as a factor in the production of insanity, neurasthenia must be considered the most important. The largest proportion of hospital admissions, received in an acute stage, have a history of neurasthenia. It is fitly called the soil out of which insanity develops." We all recognize insanity as one of the great evils threatening modern life. Do these authoritative words establish an etiologic relation between insanity and noise? But what of the relation of noise to the usual every-day life, usually esteemed healthy. Who shall say how far the high-strung, nervous, active temperament of the American people is due to the noise with which they choose to surround their daily lives? Surely, it is a factor which can not be entirely disregarded. Only physicians

know how important this temperament is in the inception, course and convalescence of disease.

Finally, we may properly consider the children. They are notoriously the cause of noise. What effect does noise have upon them? Holt says functional nervous diseases are steadily increasing among young children, and ascribes this increase to playing with them, "stimulating to laughter and exciting them by sights, sounds or merriments until they shriek with apparent delight." He advises that all such romping and playing during the first year at least be absolutely prohibited. During the first three years sleep is not very deep and hence demands attention to quiet surroundings.

We have then found noise a factor in the causation of certain ear diseases, in the course of many acute and general systemic diseases, in the etiology of some nervous diseases, chiefly neurasthenia and to some extent in the general health of the community. What line of action is open to us as students of preventive medicine? First, careful study is demanded of specialists, general practitioners and inventors to devise some protection for the ears of those who must work in the midst of a continuous din. Cotton has been used, but is inefficient. It is no slight matter to have such a large number of people continually added to our population, nearly or wholly deprived of their hearing. Many of them must become, sooner or later, a charge upon the public, and all of them are to a great degree rendered incapable of work. Protection to the eyes is guaranteed by law. Why not for the ears? Moreover, it seems probable that a careful examination of manufactories will show that much of the noise is unnecessary. If it were realized that the noise is really harmful, quiet would be secured by the same methods that we have good air and suitable light. It will cost some money, but when the people demand quiet the capitalist must furnish it. As usual the physician must lead the way.

If, now, we turn to noises outside of factories, there is also much to be accomplished. Pavements may be made smoother, as they are in Washington, D. C.; carriages may run more quietly, as for example by the addition of rubber tires; street cars and steam cars can run more quietly by care in the construction of roadbed and cars, and in the running of the cars; heavy teams may be so constructed and loaded as to avoid the dreadful jar, clatter and crash so often heard on our streets; hurdy-gurdies, handorgans, street-venders and newsboys may be restricted in time, place and calls; shrieking whistles and jangling bells may be abolished. These are but examples. Many other possible regulations will occur to you. It will require time and work and money. As physicians we must believe that quiet is a great essential to good health and then we must persuade the people that our belief is well founded.

A STRIKING ANALOGY BETWEEN THE PHYSIOLOGY OF ANIMALS AND THAT OF PLANTS.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY EDWARD DAVIES McDANIEL, A.M., M.D., LL.D.
CAMDEN, ALA.

There is a unity of plan in the anatomy and physiology of plants and animals that affords one of the most striking, most forcible and most beautiful of the evidences of the unity of nature. This unity of plan, in addition to its great but overlooked importance in comparative anatomy and physiology, is also of so great consequence and utility in human physiology and dietetics as to demand from physicians constant consideration and utilization. It is so plain and easy to be understood, that it may be rapidly and satisfactorily traced, in the following illustration from plant

which the tree derives its pabulum, and into which it discharges excrementitious matters. Below, the tree divides into large roots, which divide and subdivide into smaller portions until, in almost capillary attenuation, they permeate the soil—the other great source of food-supply and of waste discharge.

If we strip away the leaves, leaf-stems and small branches, we will have left, above the trunk, only the large limbs, which we can conceive to be hollow like the fingers of a glove, and if we invert these into the upper end of the trunk, conceived also to be hollow, and then imagine the leaves, stems and small branches to be all restored to their former places, the new arrangement will represent the air-tubes and lungs, through and into which the air enters the chest to furnish food to and remove excrementitious matters from the like parts as before.

If we conceive the like change of arrangement applied to the roots and rootlets of the tree, we will have the absorbent and secernent surface of the roots and

to man, by going from left to right, or from man to plant, by going from right to left. All that is needed here is to start at the man, as every hearer will desire the pleasure of returning by himself back to the plant.

The tree, as is seen, ends above in large limbs, branching again and again into smaller and smaller portions, and finally terminating in leaves that spread out into the air—one of the two great sources from

rootlets in apposition, with an internal field of supply and discharge—of endosmose and exosmose—i. e., a soil. However, this soil is unbounded, stationary and permanent, but is of limited supply and must be regularly renewed. There must be a receptacle with proper devices for income and outgo. Such devices are furnished in locomotor organs for reaching a food-supply, in prehensile organs for its appropriation, in

an alimentary canal for its receptacle, and in a proper outlet for residual and excrementitious substances.

The relationship between the foods and excrementitious matters of plants and of animals may be studied in connection with the illustration, and also the importance of remembering in dietetics and therapeutics, the great importance of the proper management of the contents of the alimentary canal to man's health and life.

DEVELOPMENT OF THE VITAL FORCE.

A PHYSIOLOGIC CONSIDERATION OF SOME OF THE FEATURES.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

It is important to bear in mind the dictum of the great German pathologist, Professor Virchow: *omnis cellula e cellula*. All our experiences, whether they have been directed in the search for facts among the elements of the vegetable or among those of the animal kingdom, tend to establish this apothegm as a truism.

The questions are often asked: Whence came the first cellule? Was it a development from an atom? What was its previous physical constitution? In reply, it seems but proper to say that the introduction of such inquiries is merely the result of premature consideration. In the discussion of the subject before us we will not say, however, that the examination of some facts touching upon the questions raised is not one of the objects that can come properly within our purview. Reference to the subject of the divisibility of matter may serve to awaken in us some thoughts on the question.

It is generally admitted that there is no definite limit to the properties of bodies by which their parts are capable of separation. However small a particle of matter may be, it is impossible to conceive that it can not again be divided. There may be, nevertheless, a speculative line of demarkation beyond which bodies can not be divided by the ordinary means that are within our present control. This inability on the part of mankind to accomplish more, does not affect the principle by which the disintegration of substances about us is continuously carried on. A grain of musk will sometimes diffuse its particles so as to scent a room for years, without losing any of its apparent weight. A dog will often detect his master's footsteps or the way of traveling through crowded streets or frequented roads by the mere scent, or the sensible appreciation of particles that have been exhaled from the owner's clothing or from his person. This is another proof of the exceeding attrition which matters may undergo and still have physical properties capable of being recognized.

In speaking of the cellule it is reasonable to infer that there have been variations as to its extension and form from the earlier parent cell. The nerve or ganglion cells of man and the vertebrates differ greatly in form, and vary in size from 10 to 100 microns. The cells of the motor areas are for the most part the larger. The earth during the earlier periods underwent many great revolutions. The atmosphere was constituted largely of nitrogen, and this condition of

the air must have continued until some forms of vegetation had taken on permanent activity, by the gradual evolution of oxygen from the elements that were subject to disintegration and change. The anaërobic cellules which subsist through the medium of the fermentation they produce, assumed from the increasing contact with the oxygen the nature of aërobic organisms. The changes through which such cellular bodies passed could not have been other than of a slow type. The earth, in some form and extension, must be of great antiquity, if not of beginninglessness.¹

Though there are many indications that the earth has undergone vast and mighty change, there is no real proof that the whole mass at any one time was in a molten state. Assuming that such was the case the atmosphere surrounding it may not have been so affected as not to have been a center for fostering some of the various forms of cellules. The interior of the earth is almost entirely unknown; the depth which we have been able to penetrate is scarcely to be reckoned when the whole diameter is taken into consideration. The theory deduced on account of the gradual increase of the temperature as we descend, that the earth is still in a molten state, and that we are living upon a mere crust, as it were, is based upon a most unstable foundation. Paley was once confronted with the question as to the eternity of matter. He disposed of the subject by saying that all the various parts of the universe presented indications of being the work of design, and if of design, then must have been effected by a designer. Paley compared the structure and composition of various bodies to those of a watch which might be found on a roadside. Each part of the timepiece being so constructed as to depend upon the proper working of the other parts, would impress any one who might be wholly unacquainted with the character and uses of such a device, that it was the result of design and of a designer. Paley, it must be admitted, was a pleasing and gifted writer, but he was quite unacquainted with the more modern methods of investigation and results of the inquiry of the inconstancy and transmutation of the species.

As before remarked, there must have been a gradual evolution of the aërobic from the anaërobic cellule. After the oxygen became more freely disengaged from the deeper centers, the formation of the nervous cerebro-spinal axis took place, and its development continued until it reached the stages of the various types under which it is now represented. By slow degrees the environment of the cellule improved; it was then able to appropriate to its growth a more choice pabulum, and this was transmitted to the central parts, where the structures became more highly vitalized. The effete matter was then extruded toward the surface. In this way substances of the cell, says a writer, assumed a greater activity until there appeared ele-

¹ The authority for the creation of the heavens and of the earth rests entirely upon interpretations of the "sacred writ." The term *bara*, occurring in Genesis and translated "created," is used in Isaiah, where Jerusalem is spoken of as "created a rejoicing, that is, caused her to rejoice." The word means primarily "to cut" or "to carve" of materials that existed before the cutting or carving took place. In another passage the word *bara* is used in speaking of begetting a son. We all have our ideas how cities have been built and have been made sources of pride and rejoicing to their inhabitants, and how sons or children have been begotten or produced. The various agencies employed by mankind in accomplishing any great object or event are frequently represented as being the attributes or instruments belonging to a higher power. So also the results of the action of inanimate agencies, as heat, light, and electricity, have often been described as the workings of a supreme being. These considerations, though born of our religious consciousness or deduced from metaphysical inquiries where the ultimate basis of our being is to be differentiated from its phenomenal aspects, should occupy, nevertheless, no important place in a scientific investigation.

ments from which contractile tissue and muscular sense were developed.

That principle or grade of intelligence, which in animals we denominate as "instinct,"² must have been the gradual result of chance acts put forth, either for the purpose of preservation from danger or for greater comfort and growth in their living. When we come to analyze carefully our own actions and to compare them with those of the lower forms of animal life, we shall find that they are largely the result of association and of learning by experience. These perceptions in animals are not the glimmerings of lapsed intelligence, for that view would imply that the ancestors were superior in knowledge to their descendants. All observation and experience show that there has been a gradual progress in brain power in animals even in the forms we call protozoa.

Human beings, it has been claimed, are superior to animals on account of the power of reason; that is, that mankind possesses the power of ratiocinative processes or of presenting syllogistic arguments, of generalizing and of drawing conclusions. As we study more thoroughly this phase of the human mind we shall be forced to conclude that this attitude or attainment is not of so great importance as has often been represented. Most people can reason correctly and can arrive at proper conclusions provided the premises they choose are true. In order to have true premises man must not overlook the results of his experience. An animal does the same. Every animal must be regarded as something more than a recorder and transmitter of impressions. His impulses are the results of his sensations. The same is true of man, though in a higher degree, on account of his cerebral or encephalic centers having reached a larger and more powerful development, from a more prolonged and active exercise of those parts. A good example of an animal's power of reasoning is seen in the study of the beaver, whose skill in constructing his house and in damming a stream is remarkable. The animals when preparing their lodges on the banks of a river or lake are occasionally overtaken by floods, and so some of them lose their lives. If they were to build their huts far enough away to be safe from the destructive action of the higher rise of floods, their escape from the huntsmen, who are their greatest enemies, would not be so easy.

The further we carry on our researches regarding the nature and value of ratiocinative processes, the less will we consider such operations as the greatest of all attainments. What remarkable discoveries in art or science have been made by relying essentially upon the methods of inductive philosophy? Most of the great achievements have been made by the persons who have been well versed in the details of similar methods of procedure or in the mechanism of works that afford light respecting the new invention. Harvey, in reply to the question as to what first gave him the idea of the circulation of the blood, said that the valves of the veins pointed away from the central organ, the heart, and that this fact led him to believe that they must have been concerned in the movement of the blood in the heart and arteries. This celebrated physician and surgeon, it must be remembered, had, before he made his discovery, been an accomplished anatomist. He had made himself master upon the

subject of the views of Servetus, of Columbus, of Cæsalpin and of other great investigators, who, it appears, were on the verge of interpreting the principle by which the motion of the blood was controlled.

The knowledge of all principles underlying science generally has slowly been evolved. The same is true in regard to the conception of a plan for the efficient working of the steam engine and of gaining a knowledge of the most available materials for its construction. It has taken ages for man to learn how to describe correctly the several parts or bones of the skeleton, or the different portions of a plant and flower, as their several characteristics are now studied and set forth. The nervous cerebro-spinal axis of man, like that of any animal, was constituted originally of a mere entanglement of developing primitive cellulæ.

Man's adaptation to his environment was undoubtedly accidental, though it proved favorable to his growth, progress, and attainment. He is often too apt to boast of his superiority over some of his apparently weaker neighbors, just as one nation regards its own material possessions and its opportunities as of far greater consequence than those within the reach of other nations. Referring again to the power of reason as measured by the scale of what are called logical conclusions, how very fallacious this attribute will often prove when implicit trust is had in the deductions that are reached through its operation.

The consultant says that general anasarca, or dropsy, in the human body is dependent upon one of three causes of disease, viz., upon disease of the heart, of the liver, or of the kidneys. Examination showed that the heart was not primarily affected; the liver was also regarded as not abnormally involved. The great edema must therefore be, in accordance with the general proposition enunciated, due to original disease of the kidneys. The autopsy showed, however, that the cause of death was owing to pressure upon the ureters of morbid growths (uterine fibroids) which had been the *fons et origo* of all the untoward symptoms. Had a little more attention been paid by the advisers to the formation and effects of pelvic neoplasms and to the results of inflammatory conditions, and less trust been placed in the conclusions drawn by reasoning without the help of knowledge and experience derived from such special study, the patient's suffering might have been relieved and her life prolonged by the adoption of proper, timely surgical methods of treatment.

Facts are often wrongly interpreted by regarding certain phenomena as the result of laws of the animal economy. If by law we mean that certain special phenomena occur after the appearance of particular conditions, there can be no objection to using the term "laws" for phenomena. When we assert that such phenomena are the results of a law established by a lawgiver whose dictum is irrevocable, we deceive ourselves and thus give color to the conclusion that all remedial measures for relief are useless.

By the term "law" we can mean no more than that certain results follow when certain conditions are presented in accordance with special observed facts which have previously been ascertained. We know that when chlorin and sodium in limited quantities, and under the influence of a particular temperature, are brought together the formation of common salt will be the result. Should the condition of our

² See Prof. H. W. Parker's interesting article on "The Mystery of Animal Minds," in the February number of Popular Science News, 1898; also in a previous number of the same journal.

atmosphere undergo a material permanent change, such a product as salt by the union of the two elements might not be the result. Assuming that such a physical atmospheric change should supervene, we can not otherwise conceive than that the principle essential to the formation of chlorid of sodium must have been beginningless. The departure from the occurrence of such results can only take place during the presence of other conditions. Should our entire planets, as it is possible for the human mind to apprehend, be so heated or melted as to destroy apparently all animal and vegetable life, as has seemingly prevailed within its structure during the several geologic periods which may have existed, it would be altogether likely that life of such nature and character would again recur after the subsidence of the heat or of the caloric that would be engendered by the fusion of matters, though it would undoubtedly require the lapse of centuries for its reduction. The ebb and flow of tides which would take place would be on a scale that would be almost incomprehensible. The enormous columns of clouds that would be formed from the ebullition of all the watery elements, though destructive to the larger living organisms, would nevertheless waft volumes of cellulæ far beyond the border lines of the consuming heat evolved. Living cellulæ would thus be preserved and their multiplication in some form would be continued. The diameter of such cellulæ might gradually undergo, during the subsequent processes of their formation, material diminution. The aerobic organisms would assume, as before stated, more and more the nature of anaërobic bodies, or of other minute forms of life, dependent on the pabulum which could be appropriated from the circumfusa in which they would be enveloped.

In this connection it might not be improper to state again that carefully recorded experience and close observation tend to show that all forms of animal life, except those in which morbid changes have occurred, have materially advanced to a higher state of development. Even those we denominate as the protozoa have progressed and undergone division into branches of a higher grade. How impossible would be the accomplishment of the task, should any one attempt to enumerate the various cycles or eons that elapse before a simple unicellular protoplasm can become so differentiated as to reach the higher grade of organisms.

Who could say what had been the history of each single class of primitive cells before it assumed a more complex structure? We may denominate such organisms unaltered bodies or forms of life, but, as before remarked, we can not say that such simple bodies have always been in such a state, or that such unicellular organisms have not previously had at varying intervals an innumerable number of unfoldments and regressions.

SOCIETY PROCEEDINGS.

Chicago Academy of Medicine.

Regular Meeting, Dec. 9, 1898.

Prof. C. S. N. HALBERG officiated as chairman of the meeting. Dr. GEORGE W. JOHNSON of Dunning, Ill., read a paper entitled

A CONTRIBUTION TO THE STUDY OF THE BLOOD OF TUBERCULAR PATIENTS.

He said that hematology was yet but imperfectly developed, and like many other methods of clinical examination, was

replete with error. It seldom gave a pathognomonic diagnosis, but often gave a protosight of data that can be detected in no other way. Its limits of usefulness in the practice of medicine are yet undefined. But it has come to be of such importance of late, that scarcely any clinical examination is complete without an examination of the blood. This is especially true of the chronic infectious diseases, and more particularly of tuberculosis. Anent the blood of tubercular patients, it is stated by an eminent authority on hematology, that while the patients appear to be profoundly anemic, their erythrocytes are seldom diminished in number and the hemoglobin is usually up to par, or but slightly below it. The question is therefore asked, "What is the cause of the apparent anemia in tubercular patients?"

It is the purpose of the paper to report observations on the blood of fifty tubercular patients in the advanced stage of the disease. Every possible source of error known to the author was eliminated or reduced to a minimum. A diagnosis of tuberculosis of the lungs was positively established by microscopic examination of the sputum. That the exact extent of the disease might be known and no other pathologic process present to influence the elements of the blood, a thorough physical examination was made. Especial attention was paid to cavity formation, with the idea of determining the presence or absence of leucocytosis in such conditions. The technic was essentially that detailed in Cabot's work on the blood. Clinical notes were taken on age, sex, duration of illness, family history, presence or absence of hemoptysis or hemorrhages, afternoon temperature and somatic condition. Unfortunately, the patient's word had to be taken as to the family history. This, however, was unimportant. In the microscopic examination of the sputum, note was made of the presence or absence of strepto- or staphylococci, for it is stated by Leyden, in "Musser's Medical Diagnosis," that pus micro organisms were not found in the purulent contents of tubercular cavities. They were found in great abundance in each one of the fifty cases detailed in this paper.

Hemoglobin.—Two methods of estimating the percentage of hemoglobin were resorted to: that by Fleischl's hemometer, and Hammerschlag's specific gravity test. In these cases Gloischl's instrument was more accurate. The specific gravity test invariably registered too high a percentage. The best chemicals were used, with accurately tested Squibb's urinometer. Repeated tests were made and by different persons, with the same results. The corpuscle index was estimated from the percentage of hemoglobin as read from Fleischl's instrument. In Germany, Jellinek has been experimenting of late with an instrument called Jolle's ferrometer. This is an instrument for estimating the amount of iron in the blood. He reports eight cases of secondary anemia in which the hemoglobinometer gave readings much higher than those recorded by the ferrometer, and suggests that poorly oxidized blood may give a higher hemoglobin per cent. than the amount of iron in the blood would warrant. The hemoglobin per cent. in Dr. Johnson's cases was far below normal in every instance, notwithstanding a new instrument was used, which always reads higher than one in long use. The blood was always very dark and watery, being difficult to save till taken.

Chlorosis.—This condition was met with in eight cases. Notwithstanding that it is seldom met with in males, five of these eight cases were in male patients. It is a fact that no hard and well-defined line can be drawn between mild cases of secondary anemia and chlorosis, but from the classic symptoms laid down for chlorosis, these cases would most certainly and more properly come under chlorosis. The percentage of hemoglobin was very low, even to oligochromemia; the erythrocytes but slightly diminished in number and smaller in size than normal, with now and then well-marked necrobiotic changes. There was always leucocytosis, which is not usually true of uncomplicated chlorosis.

Leucocytes.—There is always a leucocytosis if cavities are present, and the vital resistance of the patient is not too low. The number of leucocytes will be in proportion to the virulence and extent of the septic process and the vital resistance of the patient. If the septic process is extensive and the patient extremely asthenic, there will be hypoleucocytosis. Cavities were demonstrated in twenty-eight of the cases. Of this number, twenty-six had marked leucocytosis, the other two were very asthenic. The white cells were greatly increased in nineteen of the twenty-two remaining cases in which cavities were not demonstrated. The remaining three were also asthenic. Leucocytosis, therefore, occurred in forty-five of the fifty cases. Pathologic leucocytosis is diagnostic of cavity formation, although the cavity can not be demonstrated by physical examination. The absence of leucocytosis precluded cavity formation in fairly sthenic cases.

In cases of chlorosis there is lymphocytosis. In secondary anemia the adult lymphocytes are the more numerous. Polymorphonuclear neutrophils are abundant in septic cases. If there is an asthmatic or dysphonetic condition, the eosinophils will be increased. Such was the observation in these cases. Ehrlich's triple stain was used in the preparation of the slides. Neusser's granules were seen in a number of cases, but were not constantly present, or could not be detected from the granular appearance of the eosinophils. They appear as separate bodies, lying in the protoplasm immediately around the nucleus, and are most commonly seen in the mononuclear variety. They are considered to be peculiar to chronic tuberculosis and are indicative of uric acid diathesis. Among the cases was one of Addison's disease. In this case the leucocytes were all more or less granular, the granules being finer than those seen on the eosinophils, and darker, like small grains of powder.

Erythrocytes.—Well defined necrobiotic changes were noted in thirty-six of the fifty cases. Of these thirty-six cases, twenty-eight had secondary anemia. Both hemoglobin and the number of erythrocytes were diminished, with necrobiotic changes in the erythrocytes, such as irregularity in size, none being larger than normal, while some were normal and others showing poikilocytosis, oligochromemia and oligocythemia, together with a diminished number of leucocytes and an increased number of adult lymphocytes and normoblasts. The degree of such changes was, of course, varied, and there was usually leucocytosis, which is most always true of secondary anemia.

Recapitulation.—The hemoglobin was far below normal in each of these cases. Chlorosis was met with in eight patients. In these eight cases there was oligochromemia, normal or nearly normal number of erythrocytes, diminished diameter of erythrocytes, with occasional necrobiotic changes, lymphocytosis, normoblasts, and diminished number of adult lymphocytes, and low corpuscle index.

Dr. HOMER M. THOMAS.—The able paper presented by Dr. Johnson is one of widespread interest, not alone to those especially interested in tubercular disease, but to the profession at large. It represents a vast amount of painstaking, thorough and scientific work. The detail of blood examination in tubercular disease is one of elaborate technic. The study of hematology, as we know, is as yet imperfectly developed, and while the present methods of clinical examination are thorough and up-to-date in every particular, it is possible that errors may be discovered with improved technic.

The question of the apparent anemia in tubercular patients is one in which many theories have been advanced, but nothing definitely determined. We know that the paleness of the skin is not due to a lack of hemoglobin; it is only by following up lines of investigation and finding out the real cause which exists between the apparent anemia and pernicious anemia that we can acquire any data upon which to establish a differential diagnosis between the two conditions. This has been very ably accomplished by Dr. Johnson. His thesis is worthy of particular commendation, because he does not attempt to dogmatize, to establish a theory upon the results of his findings, but rather to make a plain statement of facts and allow us to draw from these facts our own deductions.

It has been stated by Leyden in "Musser's Medical Diagnosis," that pus micro-organisms were not found in the purulent contents of tubercular cavities. In Dr. Johnson's fifty cases pus micro-organisms were found in great abundance in each one of the cases. This discrepancy in statement may be due to the fact that in Leyden's cases there existed auto-infection without communication of the cavities with the larger bronchial tracts; while in those observed by Dr. Johnson there existed direct bronchial connection with the cavities, and hence mixed infection resulted. These observations will go a long way toward placing upon a firm scientific basis the hematology of tubercular cases. It would be of vast scientific interest if some other observer, as fortunately situated as Dr. Johnson is, in contact with tubercular cases, could make a similar series of examinations. Then a comparative analysis could be instituted between the two series, and discrepancies and agreements might be readily ascertained.

I wish to congratulate Dr. Johnson on the scientific character of his work, and hope that this series of cases may be but the beginning of more and more work in this interesting and invaluable line of investigation.

Dr. R. B. PREBLE.—I appreciate very fully the labor that Dr. Johnson must have expended upon this paper. There is no work which comes to the clinician that is more trying and requires more patience than that of hematology, and at the same time, it must be confessed, there is scarcely any work which brings us so little true satisfaction.

Certain conclusions were drawn by the essayist which, it seems to me, were rather strongly stated. For example, the statement that a leucocytosis is pathognomonic of the presence of cavities, although we are unable to demonstrate them by physical signs, can not be substantiated, because the leucocytosis which we find in cases in which cavities can be demonstrated is not due to the presence of cavities themselves, but to the presence of bacteria which give rise to cavity formation. These cavities are due not so much to the tubercular infection as to the mixed infection. If we have the latter without cavity formation we find leucocytosis also. So that the most we can infer from the presence of leucocytosis is that we have not a pure tubercular infection, but that we have added to it the more active pus bacteria, especially pus cocci.

It is interesting to note that Dr. Johnson has run across cases of chlorosis. The dividing line between chlorosis and secondary anemia is not by any means a sharp one, so that cases of chlorosis and secondary anemia are not easily differentiated. It is interesting to note in this connection, that one of the questions which must always be considered when we come in contact with chlorosis is whether we have a case of chlorosis or one of incipient tuberculosis under the picture of chlorosis. This frequently happens, especially in girls. They present apparently a chlorosis, and it is found later on not to be true chlorosis but incipient tuberculosis.

I think Dr. Johnson is right with reference to his statement of Neusser's granules. It is well known that Neusser is a little inclined to attach too much significance to these granules, and yet one hesitates a good deal to question his conclusions, because he is a man of such great painstaking and exactness. It was my pleasure to listen to Neusser's lectures for a number of months. He is a man who is known among his immediate associates as one who is extremely careful both in his work and in making statements. He writes but little, but what he does is very good. While it would seem as if Neusser had overdrawn his conclusions, still one hesitates to question anything that he says.

Dr. JAMES G. KIERNAN.—It seems to me that a number of points in general pathology, suggested by the paper of Dr. Johnson, ought to be considered. For instance, take the question of chlorosis. At one time the attempt was made to demarcate hysteria from certain symptoms which occurred in the female from certain symptoms of precisely the same character which appeared in the male. Here, as with chlorosis, the question was a difficult one to determine, because the female is more liable to certain symptoms. Certainly, from this standpoint, Dr. Preble's opinion regarding chlorosis does not seem to me to cover the point entirely. While it is true that chlorosis is premonitory of a large number of cases of tuberculosis, and while it is equally certain that chlorosis occurs in all three types of the tubercular diathesis, is it anything more than the demonstration of the fact that a culture medium for the development of the tubercle bacillus is produced by those conditions? Some years ago a very valuable brochure was published in a Herman series of clinical lectures by Sokolowski, in which he discussed a number of conditions mimicking tuberculosis. In a large number of these conditions, while hematologic factors were not narrated, clinical phenomena were. These seemed to indicate that chlorotic conditions resembling those occurring in the preliminary stage of tuberculosis were present in a number of cases of malaria, post-pregnancy and nervous exhaustion states. On the other hand, Sokolowski pointed out that prominent among the tubercular affections which mimic other diseases is pseudo-chlorosis. For a long time, he remarked, a certain connection between chlorosis and pulmonary tuberculosis had been noticed. Some forms of chlorosis attacking young women at puberty would obstinately resist otherwise successful treatment and gradually pass into lung tuberculosis. The opinion obtained that the condition was simple chlorosis which from some obscure cause passed into phthisis. Trousseau first called attention to this condition, which he termed pseudo-chlorosis, and showed it was a precursor of phthisis. The pallor of pseudo-chlorosis is, as Sée has pointed out, often distinguishable from that of chlorosis. The pallor of chlorosis is a waxy one shading into green. The pallor in pseudo-chlorosis is bluish-gray shading into ashen. It is of interest, therefore, to find that hematologic observation has confirmed these older observations in clinical medicine and has pointed out a basis for the semeiology. It is not surprising, therefore, that there should be conditions occurring in both male and female, who are victims of tuberculosis, which will mimic, if not actually be, chlorosis, and which is practically a culture medium for the development of tubercle bacilli.

With regard to the question of leucocytosis and cavity formation raised by Dr. Preble, there exists another factor in addition to what he called the most active agents of degeneration,

the staphylococci, the streptococci, and the pus cocci in general. There is still that tendency from an expression of constitutional defect, in addition to the onslaught of the pus cocci, aided by the tubercle bacilli. I understood Dr. Johnson as saying that the condition prior to cavity formation was one of leucocytosis.

Dr. JOHNSON—I simply stated that where there was pus infection, even where there could not be a cavity demonstrated, leucocytosis was diagnostic of cavity formation, and I simply meant that it was diagnostic of bronchiectatic abscesses and smaller abscesses, which I believe would be difficult to demonstrate physically.

Dr. KIERNAN—Taking another phase of your paper, would you regard leucocytosis as an expression of a defect of vital resistance, or of the opposite condition—an attempt at repair?

Dr. JOHNSON—If there be a leucocytosis, I consider it an attempt at repair.

Dr. KIERNAN—That was precisely the position assumed by Sokolowski. In accordance with the usual laws of pathology, when there is an onslaught by active organisms, like the pus cocci, there is an attempt at excess of the white corpuscles, and hence, under ordinary pathologic laws, that should be expected in the case of a cavity where the vital resistance was sufficient, rather than the reverse. It seems to me, that is an expression of a pathologic law.

I do not think Dr. Johnson has taken too positive a standpoint in his paper. His findings have been merely put as strongly suggestive rather than as demonstrative. Considered from that standpoint, it is an extremely valuable contribution. Of course, there need to be undertaken a large number of control experiments along this line, but we must not forget that in hematology, as elsewhere, the old fiat that was pointed out by Bacon in his "Idols," that is, a man takes a label and proceeds to measure everything by it without reference to control experiments. This paper can only be criticised from its suggestive standpoint. It must be remembered that in pulmonary tuberculosis there are a great many phenomena such as occur in a large number of exhaustional conditions. They occur with greater rapidity; they are more demonstrable; they are mingled more with the minor phenomena produced by the tubercular changes, but still in a general way they resemble the other conditions of exhaustion. This is peculiarly true of the psychoses produced by tuberculosis. That being the case, one would expect a large number of phenomena having a close resemblance to other constitutional conditions modified more or less by the local states. As Dr. Preble has pointed out, a good many of the most difficult conditions that have to be dealt with in considering pulmonary tuberculosis are due rather to the secondary ravages of pus cocci than to the original ravages of the tubercle bacillus itself. But it should also be remembered, that while the tubercle bacilli can produce a constitutional condition which predisposes to pus cocci ravages, yet behind the tuberculous condition are a number of constitutional states, and all of these should be considered.

I would like to see, what I think will ultimately be made, precisely the same observations along the line of what Sokolowski has called pseudo-tuberculosis that have been made here, that is, observations to determine how much of these hematologic phenomena are produced by constitutional conditions which underlie and predispose to the tubercular condition, and how much of them are produced by the secondary consequences of the tubercular infection.

Dr. J. A. WESNER—Dr. Johnson has not overstated the case in saying that the specific gravity and Fleischl's method of estimating hemoglobin are very inaccurate. In normal blood all the hemoglobin is not oxyhemoglobin, but some of it is hemoglobin; furthermore, oxyhemoglobin is changed quite rapidly in the presence of air, etc. Fleischl's hemometer is standardized to the color of oxyhemoglobin and it is this variation of color of the different colors of hemoglobins which makes this error. Hoppe-Seyler's method is very accurate and simple; he uses an apparatus composed of two compartments. One of these he fills with a standard carbonic acid hemoglobin solution, and in the other he places the blood to be examined, and dilutes up to the mark with water, and then passes in carbon monoxid gas to saturation. We now have two hemoglobins, both of the same chemic composition, and, therefore, of the same color. We could apply the same method to Fleischl's hemometer; instead of using an oxyhemoglobin prism, use a carbonic acid hemoglobin prism, and then saturate the drawn blood with carbon monoxid and place in the disc and proceed the same as given under the Fleischl's method.

With reference to pathologic leucocytes, I think Dr. Johnson's answer to Dr. Kiernan, that it is an effort at repair, is correct, and I believe if the urine had been tested in all of these cases albumose would have been found. This is always

indicative of either pus formation or chronic suppuration. In simple tuberculosis we will not find any albumose in the urine. When we have mixed infection, especially when there is an effort at repair, albumose will be found in the urine.

Dr. JOHNSON (closing the discussion)—I wish to make myself clearly understood in regard to pathologic leucocytosis. I believe it is universally conceded by pathologists that where there is a pathologic leucocytosis, there is always a septic process, and that was the thought expressed in my paper. I desired to be understood as saying that where there are pus micro-organisms present, such as streptococci and staphylococci, and where there are purulent discharges in the sputum, demonstrated by microscopic examination, there is the formation of bronchiectatic abscesses. I stated in my paper that there are various degrees of cavity formation, as well as various degrees in the septic process, and that is what I meant when I stated that a pathologic leucocytosis is diagnostic of cavity formation, although the cavity could not be demonstrated by physical examination. I desire to thank the members of the Academy for their attention and discussion of my paper.

Southern Surgical and Gynecological Association.

Eleventh Annual Meeting, Dec. 6-8, 1898.

(Concluded from page 1473).

Dr. A. M. CARTLEDGE of Louisville contributed a paper entitled

WHEN SHOULD WE OPERATE FOR APPENDICITIS?

He drew the following conclusions: 1. Probably 98 per cent. of the patients who die of acute appendicitis without operation have the fulminating variety of disease. Operation, to be of service, must be done in the first twenty-four hours, better in the first twelve. 2. In view of the fact that we have no means of knowing the probable course of a given attack of appendicitis, operation, when possible, should be performed within the first twenty-four hours after the onset of symptoms. 3. Patients seen after the third day should not be operated on until over the attack, or until purulent formations, if such take place, have been walled off and the patient practically rid of general sepsis. An exception to this rule is the rupture of an appendiceal abscess into the peritoneal cavity, a very rare accident, when abdominal section should be immediately performed. 4. Probably as many patients recover from general septic peritonitis by stimulants and purgatives as by operations. In either event, if it is a case of true general septic peritonitis, the mortality will not be far from 95 per cent. Contributions to medical literature would indicate that there is a sad need, on the part of the profession, of more definite views as to the nature of this disease. If operated on at all, no attempt at general cleansing of the cavity should be practiced; quickly assist nature to take care of the desperate patients, by removing the source of the foci. To do more is to add the shock of an unbearable operation to an already nearly exhausted vitality. 5. Subject to interval operation patients who have suffered unmistakable attacks of the disease. 6. Do not operate too soon after a severe attack with many adhesions; the operation will be greatly simplified by waiting a few weeks longer. In the meantime, keep the patient upon light diet and little exercise. Patients do not usually have a recurrence until the adhesions or splints have been removed by absorption. The mortality from interval operations should not be more than 1 per cent. In drawing the above conclusions, Dr. Cartledge wishes it to be distinctly and thoroughly understood that they are not to be considered in the sense of hard and fast rules, but simply as a working basis for the general practitioner.

Dr. GEORGE H. NOBLE of Atlanta read a paper on

URETERAL ANASTOMOSIS.

He gave an analysis of thirty cases collected from literature, and divided them into two classes: 1, ureteral anastomosis, or union of the ureter end to end or side to side; 2, ureteral implantation into the bladder. July 2, 1898, the essayist ligated the ureter with the ovarian vessels and Fallopian tubes in a case of large extraperitoneal fibroma. This was the very first ligature applied in doing the hysterectomy. The bladder end was split about three-eighths of an inch, as much of the mucous membrane as could be drawn out was cut away; then the upper or kidney end of the ureter was invaginated into it, using a mattress suture for the purpose. The split was then closed with fine sutures, making a snugly fitting cuff around the opposing end with no mucosa intervening. Small silk was used to stitch the raw edge of the inferior segment around and to the sides of the upper section. A peritoneal cuff was thrown around the joint thus made and the ureter buried behind the

peritoneum. The entire work was conducted with the aid of a ureteral catheter, which had been introduced through the ureter into the bladder and drawn out of the urethra with a pair of forceps. The upper end was passed into the kidney end of the ureter. This served a useful purpose, the entire manipulation being greatly facilitated and preventing obstruction of the ureter by crowding down the cut end of the mucosa just below the line of union. This case had suffered from absorption of pus for a number of weeks from double pyosalpinx, was emaciated and thoroughly septic. Her temperature just before going upon the operating table was 103 degrees, and had been running equally as high for the time she had been in the hospital and perhaps longer. Her pulse was 130, weak and thready. Thus this anastomosis was done under unfavorable conditions, but was successful.

In October, 1898, he did a successful resection of the left ureter in a case of extraperitoneal extension of sarcoma of the ovary. About one and a half inches of the duct was removed and the ends united as above. The peritoneum was stripped from the entire left half of the pelvis. The bladder was separated from the upper portion of the vagina, and also from the horizontal ramus of the pubic bone, and drawn up to left side to the ileopectineal line to cover or bury the ureter, and fastened with a silk suture. In this instance the ureteral catheter was introduced on the stiletto, and being stiffened by it passed directly out of urethra from the ureter; thus the use of forceps was necessary to fish it out of the bladder. Abdominal and vaginal gauze drains were used. There was no leakage.

The essayist said that there are several features necessary to success in doing ureteral anastomosis aside from thorough asepsis: 1. Perfect coaptation or invagination, which must be done in such a way that no mucous membrane can slip between the ends of the ureter. 2. The ureteral artery should be preserved in its continuity to the ends of the ureter. If this vessel be destroyed, when the ureter has been dissected loose from its attachments, it will perish beyond the point where it ceases to receive its blood-supply. The ends of the ureter should be cut back to the point where the artery is intact, lest under diminished blood-supply and tension it should perish. 3. All strain or tension must be relieved. Should union occur by first intention, the parts will separate as soon as the sutures cut out or are released. 4. There must be no obstruction to the flow of urine.

Dr. WILLIS F. WESTMORELAND of Atlanta presented a paper entitled

CARCINOMA OF THE BREAST.

He said that carcinoma now presents even a more serious problem than formerly, on account of its rapid increase. The proportionate mortality from cancer is four and a half times greater now than half a century ago. No other disease can show anything like such an immense increase. According to statistics, two out of every five cases of carcinoma in the female are of the breast. Over three-fourths of all the tumors occurring in the breast are carcinoma, or to be exact, of 637 tumors, over 503, or 83.20 per cent. were carcinoma, leaving only 107, or 16.79 per cent., representing all other forms of neoplasms. The author discussed the etiology of the disease at considerable length. Speaking of the pathology, he said there was no subject in surgery about which such divergent opinions are held. There is a wide variation in the malignancy of carcinoma, some proving fatal in less than a year, a few others taking ten or fifteen years. He divided the new varieties of carcinoma into the scirrhous and medullary or encephaloid. The former has an average duration of life of about thirty months, the latter of about twelve months. When it is considered that the skin and pectoral muscles are involved in nearly every instance in this disease, the surgeon can easily see the philosophic reasoning upon which Halstead's operation is based. The essayist follows the Halstead method in carcinoma of the breast. He believes, however, that Dr. Bloodgood was the first to demonstrate the advantages of completely cleaning out the postero-internal subscapular region by the supraclavicular route. The results of the Halstead operation, in the opinion of the essayist, depend upon the ability of the individual operator, his earliness in seeing the case and his closeness in following Halstead's technique. This operation not only requires surgical skill and experience, but proper respect for the magnitude of small things.

In the opinion of Dr. Westmoreland, no surgeon will make a satisfactory operation on his first few cases. He finds that with each case he operates more satisfactorily. The operation does not present the seriousness that its magnitude would lead us to believe. He has operated six times before his class at a public clinic and transferred the patients afterward, at times quite a distance, to their homes. In his first operations he

had some shock from exposure, but this is easily controlled by placing hot towels over the exposed surfaces. There is practically no blood lost in a properly made operation. It is better to complete the operation, grafting included, at one sitting. When, for any reason, this is not practicable, the cleaning out of the supraclavicular region and the grafting can be made at a second operation. When grafting is done at a second operation he finds it better to remove the granulations. This is best done by curetting. In two of his cases it was necessary to remove the subscapular nerves, and in another to resect the axillary vein. No unpleasant sequelæ followed in either case. He has operated upon over fifty cases of carcinoma since he began surgical work, and has always cleansed out the axilla and stripped the muscles in each case. He has been making Halstead's operation since its introduction. He does not know the results in the majority of these cases. Two of them, however, came back to him with later recurrence, one with a carcinoma of the femur five years after the operation, no local return; the other with a local return in the cicatrix nine years afterward. This case died in a short time from metastasis. He feels quite sure that these were not independent new growths. There is always one rule, that the more malignant the case, the greater the blood changes.

The primary object of the paper was to point out the fact that a careful clinical examination of each case, a record of the local conditions, the type of tumor, the blood changes, whether or not there was marrow infection, the family history, and the length of time it had existed, would not only give definite facts upon which to base a prognosis, but, if published with each case, would give all surgeons a record of infinite value for comparative purposes.

Dr. I. S. STONE of Washington, D. C., contributed a paper on

THE RARITY OF OVARIAN CYSTS IN NEGRESSES.

After several years' experience in a hospital for women, where a large number of negroes are annually treated for gynecologic diseases, and where cases of uterine myomata are frequent, the writer has noticed the extreme rarity of ovarian neoplasms and especially of the multilocular variety. He addressed letters to all the members of the Association and to several other prominent surgeons elsewhere, and of the large number who replied to his inquiry there was almost universal acquiescence in the position taken by him, save from one important medical center, i. e., New Orleans. According to the records from the hospitals of this city, cysts of the ovary of all classes are rather more frequent in the negro than in the white. Leaving aside this one source, the author advanced overwhelming testimony favoring the view that ovarian tumors are exceedingly rare in the negro race. The essayist makes a careful distinction between multilocular and unilocular cysts, because there can be no doubt about a diagnosis at the time of operation when a multilocular cyst is found. It is otherwise with parovarian cysts or those of the broad ligament, etc., which are perhaps classified as ovarian, and their removal called ovariectomy in hospital reports or operation lists, when, strictly speaking, they are not ovarian tumors. He has frequently operated for dermoid, papillomatous, parovarian and broad ligament cysts in negroes (although most of these in mixed cases), but has not seen a multilocular ovarian cyst.

Dr. F. W. PARHAM of New Orleans read a paper on

RESECTION OF THE THORACIC WALL FOR TUMORS GROWING FROM THE THORACIC SKELETON.

He reported two such operations of his own with successful results. Both operations widely opened the pleural cavity and the lung collapsed in both. In the first the collapse was relieved only when the great pectoral muscle was brought down and sutured to the rent in the pleura. In the other, signal service was rendered by the Fell-O'Dwyer apparatus for maintaining regular respiration. He believes the perfection of this apparatus and its application in skillful hands will greatly aid in the developing of the surgery of the chest. He had collected all cases operated on up to date with a mortality of 25 per cent. for the intrapleural operations for tumors of the chest wall.

Dr. W. L. ROBINSON of Danville, Va., presented

A CLINICAL REPORT ON THE USE OF ANTISTREPTOCOCCIC SERUM IN SEVEN CASES OF PUERPERAL SEPTICEMIA, FOUR OF POST-OPERATIVE SEPSIS, THREE OF SEPTIC CELLULITIS, AND TWO OF ERYSIPELAS.

The use of antistreptococcic serum in puerperal fever, septic cellulitis, post-operative sepsis and erysipelas, comprises seven cases of puerperal fever treated by him with high fever, rapid, weak pulse, characteristic breath, chilliness, nausea and insomnia, pelvic tenderness, with scanty, fetid lochia. From 12 to 20 c.c. were injected after the usual treatment had

failed, including irrigations, intra-uterine and vaginal, sealing abrasions of the cervix and perineum, saline injections, purgatives, stimulants, etc., with prompt improvement in the general condition, rapid fall of temperature, lowering of pulse-rate, and complete recovery. The effect was manifest in from eight to sixteen hours in the majority of cases. In three post-operative cases of sepsis, seemingly hopeless, all usual treatment failing, the serum in twelve hours transformed every symptom of high fever, chilliness, rapid, weak pulse, diarrhea, etc., into a hopeful condition, resulting in rapid recovery. Pain subsided in twelve hours, fever in eight hours, diarrhea in forty-eight. One was a vaginal hysterectomy; the second was operated on for the removal of pus-tubes, and the third was a vaginal hysterectomy. Three cases of septic cellulitis consisted of suppurative cellulitis of the hand, commencing in the finger, one of injury from a rusty nail, and the other from the spur of a cock. Both had been treated by general alterative tonics and locally with improved antiseptic measures, but the disease progressed daily, involving new tissue till the serum was used, which promptly arrested the progress of the disease in both cases and saved the hands. A third case was a gunshot wound of the ankle, with marked septic prostration, chills, diarrhea, etc., which was dissipated promptly by the use of the serum, so far as fever and general septic symptoms were concerned.

Two cases of erysipelas: One, 16 years of age; abscess following extraction of tooth, discharging at two points on the neck. Redness and swelling covered one-half of the face, nose and head. Temperature 104.4 degrees; pulse 140; delirium, vomiting, chilliness, etc. Ten c.c. of the serum were injected at nine p.m., resulting in fall of temperature to 100 degrees. Next morning there was complete arrest of all symptoms, followed by prompt recovery. The second case was one of nephritis; puffed eyelids and face; erysipelas of the thigh; hard, red, shiny swelling; delirium; two injections used in twenty-four hours rendered patient convalescent in thirty-six hours. The serum used was that of Parke, Davis & Co.

Dr. J. B. MURFREE, of Murfreesboro, Tenn., followed with a paper on

PENETRATING WOUNDS OF THE CHEST.

He confined his remarks largely to wounds of this region. Such a wound is produced usually, by external violence where the walls of the chest are penetrated and the offending substance enters the thoracic cavity. It is a wound where not only the chest-walls are injured, but also the tissues and often-times some of the viscera within the cavity. Penetrating wounds of the chest vary in their extent, character and severity. They vary from a small perforation with a delicate knife blade or small bullet, merely separating the tissues without inflicting any serious injury, up to a fearful laceration with great loss of tissue or serious damage to an organ produced by a large knife or a mallet ball. Wounds penetrating the chest are dangerous from hemorrhage, from the admission of air into the pleural cavity, producing collapse of the lungs, from emphysema, from empyema, from septicemia and exhaustion. When a large vessel is injured, death quickly ensues from loss of blood; while injury to smaller vessels may endanger life and even prove fatal from continued or frequently repeated hemorrhage. The symptomatology and treatment of these wounds were dwelt upon by the essayist at considerable length.

Dr. GEORGE S. BROWN, of Birmingham, Ala., reported a case of vesico-rectal fistula of eight years' standing, the result of perineal lithotomy, with cure after ten operations.

The following officers were elected for the ensuing year: President, Dr. Joseph Taber Johnson of Washington, D.C.; vice-presidents, Drs. F. W. Farham of New Orleans, and W. L. Robinson of Danville, Va.; secretary, Dr. W. E. B. Davis of Birmingham, Ala.; treasurer, Dr. A. M. Cartledge, of Louisville; to fill vacancy in the Council, Dr. L. McLane Tiffany of Baltimore.

New Orleans was elected as the next place of meeting, time to be determined by the Secretary with advice of the Council.

After the presentation and adoption of resolutions of thanks, the Association adjourned.

Cincinnati Academy of Medicine.

Regular Meeting, Dec. 6, 1898.

Dr. E. H. SHIELDS contributed a paper to the meeting entitled

THE HYPODERMIC METHOD IN THE TREATMENT OF SYPHILIS.

He had used this method in some seventy-six cases in private practice and in many more in charity work, and always with the best of results, the manifestations of the disease disappearing with from twenty-six to sixty injections. He had given

over seventeen hundred injections without abscess formation and attributed this good result to several reasons: that the injections were deep intramuscular; that he did not use calomel; that the solution used was sterile. In this latter connection he thought not enough care was taken in rendering the preparation sterile. He usually, though not invariably, used the bichlorid of mercury, and the injections were usually given about once a week. The pain of the injection was not very severe and was often preferred by the patient to the inunction treatment. He especially recommended this method in the roseola stage, when the face was involved and it was desired by the patient to most quickly rid himself of this early lesion; and also in those secondary eruptions that resisted other methods of treatment, as the so-called psoriasis palmaris luetica. In a case of iritis the pupil had responded to atropin only after the injection treatment had been instituted, though the internal administration of mercury had been pushed to the limit. (A similar experience was mentioned by one of the subsequent speakers.) Among all his cases he had had but one recurrence.

Dr. RAVOGLI opened the discussion, saying that he had read a paper on the hypodermic treatment, seventeen years ago, before the Academy. At that time, when calomel was used almost exclusively, when the injections were subcutaneous, and when but little was known of aseptic technic, abscess formation on the fifth or sixth day was very frequent. To be sure, previous to suppuration the mercury in the system had accomplished wonderful results. He himself had had one case develop gangrene, and death had almost resulted. The patient had been confined to bed many weeks. Another objection to the use of calomel was the tendency to an early production of ptialism; once injected, absorption would continue from the reservoir until the supply was exhausted. The ptialism would become worse, and nothing could be done unless the points of injection were incised. He had abandoned the method many years ago, but of late he had treated some of the inmates of the Cincinnati Hospital by hypodermic injection. He found that the neurotic condition usually present among the women of a venereal ward was greatly increased. The pain of the injection was greatly complained of, often lasting several weeks, almost always causing a decided limp on the day of the injection. Nodules were often formed at the point of the injection which persisted for months. He agreed with the essayist as to the good results obtained by this method in malignant cases of syphilis, and had often seen lesions most persistent to other methods of treatment clear up rapidly after a few injections. He thought that it was for these cases particularly this treatment should be reserved. He did not believe in treating all cases indiscriminately by means of any one method of treatment. Drs. Heidingsfeld, Merrill, Ricketts, Weaver, H. M. Brown, Marcus, Haines, and the essayist, also discussed the paper.

Dr. BYRON STANTON, local member of the Ohio State Board of Health, read some interesting facts regarding the presence of smallpox in the State of Ohio, stating that the subject was of general interest in that it had assumed almost the proportions of an epidemic, and that because the type of the disease had been almost universally mild it had been mistaken in many places for chicken-pox. The latter, to obscure matters more, had indeed been prevalent at several places where undoubted cases of smallpox were also raging. The present epidemic had begun in March of the present year, having been brought to Carroll from Georgia. Several members of an "Uncle Tom's Cabin" troupe had become infected, but the mildness of the cases baffled the attending physicians and no precautions had been taken to prevent spread. In all, about 550 persons had been attacked, almost all persons who were neither protected by a previous attack nor by vaccination. The mildness of the present epidemic is shown when it is stated but five deaths have occurred out of the total number of cases reported. Over thirty towns have suffered, including the cities of Sandusky, Cleveland, Dayton and Cincinnati. In the latter city, up to date, nine cases have been reported and isolated at the Branch Hospital. In most of these cities the "Uncle Tom" troupe had given performances. To their credit it may be said that they were unaware of the nature of the disease attacking their various members. They are now happily corralled in Cincinnati. The town that has suffered the most is Loveland, between twenty to thirty miles from Cincinnati, on the Pennsylvania Railroad. This place is not yet free from infection.

Regular Meeting, Dec. 12, 1898.

Dr. O. P. HOLT presented a patient afflicted with pernicious anemia. The principal point about the case was that the diagnosis had been positively made about two years ago (Jan-

uary, 1897), and that he had been incapacitated from work for fully a year before that time by weakness, loss of strength, palpitation and shortness of breath. He was admitted to the Cincinnati hospital, January, 1897, with the above symptoms and also with great edema of the lower extremities, the external genitals, and the face, particularly the eyelids. The skin was of a decided lemon-yellow color. He was very well developed and not emaciated. During the year of his illness he had consulted many physicians, and diagnoses of all kinds had been made: Bright's disease, heart disease, particularly malaria, but never pernicious anemia. A careful examination of the urine, quantitative, qualitative and microscopic, showed the kidneys to be normal. The heart was normal, aside from soft, blowing, systolic murmurs, not constant, heard indifferently at apex and base, which murmurs could be readily accounted for by the anemia. The lungs were normal, also the liver and spleen. There was no history of venereal disease or of alcoholism. The examination of the blood showed the reds to be in the neighborhood of one million, the whites about three thousand; the hemoglobin estimation showed the individual corpuscular richness to be above normal, taking the number of reds into consideration, so that the color index was above one. The stained specimens showed marked poikilocytosis, both in size and shape. Nucleated cells were not common, but the normoblasts exceeded the megaloblasts. This latter point—the excess of normoblasts over megaloblasts—has always been regarded as a rather favorable sign as far as prognosis is concerned. He thought that the increase in hemoglobin was due to the fact that the average size of the reds was above normal. The eye grounds were normal, and no retinal hemorrhage had developed. The stools were examined frequently for parasites, as described to be occasionally present by some observers, but none were found. Indeed, no gastrointestinal complications had been observed at any time. The patient was kept in bed, functions kept normal, and arsenic administered in the form of Fowler's solution, and gradually increased until he was taking fifteen drops three times a day without discomfort. The edema gradually disappeared, he became stronger, his red count gradually increased to almost three millions and at the end of three months he was discharged at his own request, greatly improved, as he thought well. To the present time he has been kept under observation, and during this interval has had two typical relapses, which latter are regarded as very characteristic of the disease. His last count showed the following: reds, 2,700,000; whites, 7,000 (very unusual, as a leucopenia is almost always present); hemoglobin 43 per cent., differential count (500 whites): small lymphocytes, 36 per cent.; large lymphocytes, 1.2 per cent.; neutrophils, 60.4 per cent.; eosinophiles, 2.4 per cent.; no myelocytes. While counting the five hundred whites, twenty-six normoblasts and one megaloblast were observed. In puncturing the ear to obtain the blood, the latter flows with great difficulty, and deep puncture has to be made so as to obtain sufficient blood for examination without resorting to pressure. The blood remains fluid for a long time and seems to have very little power of coagulation. Poikilocytosis, while present, is not so marked as at previous examinations. In the treatment of this disease many remedies have been used with apparently little success. While temporary improvement has followed the exhibition of several, this good effect could not be properly assigned to the drug in question, as it is well known that many cases have improved without medication, and relapses, as he had said before, were typical of the disease. Iron he regarded as useless, as the disease was not looked upon as resulting from increased destruction of reds, but to something interfering with their proper manufacture. Various body extracts have been used, but with little good effect. Bone marrow has been reported of value in some cases, but the time is not yet ripe to ascribe too much to this remedy. Arsenic, in the form of Fowler's solution, which this patient has taken freely, is looked upon by most authorities as the most valuable agent as far as we now know.

Dr. C. A. L. REED read a paper on "Fat and Fecundity," which was discussed by Drs. C. E. Caldwell, Bonifield, H. M. Brown, T. Louis Brown, Kiely, Haines, Fraid, Johnston, Ricketts, Judkins.

The French Congress of Urology.

Paris, October, 1898.

ALBARRAN, HALLE and LEGRAIN presented the subject of VESICAL INFECTION.

They stated that in 304 cases examined the bacterium coli was found 131 times, pure in 98; the pyogenic staphylococcus was found 70 times. The pyogenic streptococcus has only been

noted eighteen times in literature. In their experience gonorrheal infection very frequently depends upon the action of the gonococcus exclusively. Fraenkel's, Friedlander's and the typhus bacillus are but rarely encountered, while the Koch bacillus is among the most frequent agents of vesical infection. The recent discovery of anaerobic micro-organisms in vesical infections throws a new light on certain gangrenous and fetid processes. The diagnosis depends upon histo-bacteriologic analysis of the urine, which differentiates bacteriuria from cystitis and determines the extent of the lesions. The destruction of the micro-organisms by medical means is usually unattainable; surgical intervention is necessary to evacuate the results of stagnation of urine and apply antiseptics or open up the organ, insuring drainage and repose.

CARLIER reported two cases of vesical infection consecutive to dysentery in which the infection must have proceeded from the intestines, and yielded to energetic medication.

PICQUE extolled the value of the hypogastric incision in vesical infections except in the case of ascending infection with severe lesions of the upper urinary passages. The gravity of this operation has been much overrated.

JANET emphasized the contagiousness of vesical infections, mentioning an instance in which he found the same diplococcal bacillus in the urethritis of two men which he had noted in the bladder of their common mistress. He considers sexual relations counter-indicated in case of vesical infection, even bacteriuria. Others confirmed this statement with numerous instances of urethritis contracted from vesical infection in others.

HAMONIC recommended permanganate as an especially effective antiseptic for the bac. coli; sublimate and mercuric binoiodid for the staphyl- and streptococci; copper sulphate for the gonococcus and zinc chlorid for the Koch bacillus.

ESCAT related the case of a young man with acute gonorrhea who was seated and in erection, when another person sat down in his lap, causing a spongio-fibrous rupture of the urethra, with the immediate formation of a diffuse sanguine infiltration in the entire perineal region, and in the course of several months complete retention, with lesions requiring internal urethrotomy and dilation.

BOECKEL reported a case of rupture of the urethra back of the ligament of Carcassone, from a very violent shock to the perineum. A suprapubic median laparotomy evacuated a pus pocket and disclosed the location of the solution of continuity of the urethra, but a few weeks later symptoms of constriction required external urethrotomy, a hypogastric incision and retrograde catheterism, with a sound left for three weeks before complete recovery.

LEGUEU reported an extensive urethral breach filled by the lining process devised for vesico-vaginal fistulae. The patient kept the permanent sound twenty days, but she is now completely cured. Permanganate was preferred to protargol by several members for gonorrhea.

ESCAT proclaimed the superiority of cyanid of mercury for this affection. From 1 to 5 per cent. solutions can be used progressively and as much as a liter, without inconvenience to the organ or organism. It induces a serohematic exudation in the urethra which proves an effective serotherapy against the gonococci, and when better appreciated will render valuable services in gonorrhea and perhaps in all urinary affections.

MONOD confirmed its value from experience, although he observed that the application is sometimes painful. The pathogenesis of secondary aseptic urethritis in persons with a gonorrheal past was discussed, and instances related in which the bicycle, coitus and the immoderate use of beer produced it.

CARLIER of Lille has even observed cases of urethritis in men without venereal antecedents but addicted to beer to the extent of twenty liters in the twenty-four hours.

ABARRAN reported six observations of double angioneurectomy for hypertrophied prostate, all satisfactory and come remarkably improved. The results of vasectomy reported were twelve cures, ten improved and twelve failures, out of forty cases operated (Nicolitch), one absolute failure (Reynès). Six cases remarkably improved by the Bottini operation were reported.

COTTET described a case of acute prostatitis following a two-months' old gonorrhea, requiring the prerectal incision and evacuation of the abscess, in which the gonococcus was found pure, furnishing fine cultures. He can find no similar case in literature.

DESROS observed, in regard to prostatic calculi, that they can be reached by the perineal route if they are small or medium-sized, but if they are found too large to extract by this means, even after the perineum has been opened, the hypogastric incision must be resorted to.

A number of cases of vesical tuberculosis were reported,

cured with cystotomy, curetting and cauterizing the inner surface of the bladder.

NOGUÉS has been very successful in some recent cases with instillations of a 1 to 4 per cent. solution of ichthyol.

VIGNARD protested against the laborious enucleation of the organ, which too frequently preceded nephrotomy.

LOUVEAU does not advocate in general immediate suture of the kidney after nephrotomy for calculous anuria, but reported two observations in which the catgut suture healed by first intention without any filtering of urine through the wound.

ALBARRAN always leaves a drain in the kidney reaching to the pelvis after nephrotomy for calculous anuria. He reported several cases of pyelonephritis treated with lavages of the pelvis with boric acid water and nitrate of silver, 1 to 1000. He urged all to establish better the indications for catheterism of the ureters. He only applies it in bacteriuria in the rebellious form, and the precaution of a lavage of the kidney will forestall accidents. In severe pyonephrosis he only resorts to catheterism just before the surgical intervention.

HOGGE recommended salol, 9 grams a day, as a preliminary to catheterism of the ureters for vesical bacteriuria.

DESROS has observed chills and fever follow catheterism of the ureters and cease as the catheters were removed. In one case an intense chill followed catheterism for a severe pyonephrosis, with death in three days, suggesting caution in catheterizing.

"Essential Hematuria" is the subject announced for discussion next year.

PRACTICAL NOTES.

Plastic Surgery in the Mastoid Process.—Von Mossetig-Moorhof describes, in the *Cbl. f. Chir.* of November 19, his method of closing a defect after ablation of a cholesteatoma in the ear, and all danger of recurrence is past. He cuts a tongue-shaped flap below the defect, after freshening the edge between two parallel lines drawn around the edge of the flap. The edges of the defect were detached all around so that they could be lifted with a hook. The flap was then turned back over the defect and the edges of the flap pushed under the raised edge of the defect all around. Four stitches held it in place and the space left by the flap was sutured in a straight line. The exposed under surface of the flap covering the defect cicatrized over in his six cases in two weeks. An extraneous flap might be applied, if desired, to render the operation more cosmetically complete.

Plastic Surgery of the Eyelids.—Professor Angelucci describes the following cases as a typical illustration of his method: After removal of an ulcerated epithelioma requiring the excision of both lids, of the lachrymal gland and of some neoplastic nodules in the tissues of the orbit, two large flaps were cut, one on the brow and the other on the cheek, extending down to within one centimeter of the angle of the jaw, sliding the flaps together and suturing them with the horizontal median line of the orbit between, the eyebrow on the upper flap a little lower than its normal position. The orbital edge of each flap was sutured to the conjunctiva of the cul-de-sac, except in the internal angle, where it was sutured to the peripheral segment of the bulbar conjunctiva, which had to be detached up to the limbus. The *Rev. Gen. d'Ophthalmologie* for October 31 illustrates the results a couple of months later. The new lids work and wink well, the secretions of the conjunctival sac are sufficient to protect the corneal epithelium, and although the cosmetic results might be better, the important problem of protecting the eye is solved.

Surgical Treatment of Ulcer of the Stomach.—Berg urges the publication of all cases after having been followed long enough to determine the ultimate results, as the indications are still so uncertain. He describes thirty cases operated on. The first ten were ulcers with infiltration simulating a palpable tumor. His conclusions from the results attained were that pyloroplastics is inferior to gastro-enterostomy, which must occasionally supplement segmentary resection. The exclusion of the pylorus supplemented by gastro-enterostomy, protects

best against the danger of progressive infiltration and perforation, when it is impossible to excise it as in certain cases. Seven cases of cicatricial stenosis of the pylorus were treated with gastro-enterostomy (in one case preceded by ineffectual pyloroplastics). The rest were for various benign affections. He warns against attributing serious gastric disturbances to hernia, and advises an exploratory laparotomy when the hernia is operated on. All his cases recovered. *Nordiskt Med. Arkiv.*, xxxi, 5.

Bonain's Local Anesthesia.—This process comprises the anesthesia of the external surface of the tympanic membrane with a mixture of phenol, menthol and cocain hydrochlorate, $\frac{1}{10}$ gm., or 2 gm. of the phenol to .5 gm. or 1 gm. of the other ingredients. The internal surface of the membrane and the mucosa of the tympanum are anesthetized with two or three drops of a one-tenth solution of cocain instilled by an incision or incisions made in the membrane with a Hartman canula, mounted on a small syringe. The blood flows very little, if at all. His experience includes twenty-eight operations; paracentesis, destruction of synechiae, mobilization, ablation of the ossicles, total ablation of the tympanum, also for hypertrophied tonsils and tuberculous infiltrations and vegetations of the larynx.—*Rev. Hebdomadaire de Laryng.*, etc., November 26.

Cocain and Spartein Anesthesia.—Bagot combines spartein with cocain, which obviates the depressing effect of the cocain on the heart, while rendering the anesthesia more lasting. He has a powder prepared beforehand: cocain hydrochlorate .04 gm., and spartein sulphate .05 gm. When ready to use, the powder is dissolved in one or two cubic centimeters of boiled water. As much as eight to twelve centigrams of cocain can thus be injected in fractional injections without accident. In operating on a tumor he injects 1 c.c. of the weaker solution on one side, and waits seven or eight minutes before injecting the other side. He can then commence the operation in a few minutes on the side first injected. If the operation requires over twenty minutes, a third injection can be made, which keeps up the anesthesia for three-quarters of an hour.—*Gazette Méd. de Liège*, December 1.

Paroxysmal Hemiglobinuria.—In a discussion of several cases at the Berlin Medical Society, it was established that exposure to cold, even walking around barefooted in a bed-room, would in certain persons produce an attack of hemoglobinuria. The blood came from the ureters in one case. Avoidance of getting chilled has arrested the affection in certain cases as reported; Ewald observed that he had never derived any benefit from amyl nitrite, which has been recommended for hemoglobinuria.

Anthrax on the Nose.—A. Strubell reports a severe case of gangrenous and necrotic anthrax spreading from the tip of the nose, with chills, fever, etc., completely cured with scarcely a scar, by frequent injections of a 3 per cent. solution of carbolic, a total of 400 Pravaz' syringe-fuls in eighteen days, combined with copious stimulants, warm baths, and hot cataplasms at a temperature of 50 to 55 degrees C., applied locally every ten minutes, night and day. The growth of the anthrax bacillus is checked at 40 degrees and permanently arrested at 42. Cultures from the nose were very virulent, but no bacilli were found in the blood.—*Munich Med. Woch.*, November 29.

Aneurysms of the Arteria Ilio-femorals.—The *Vienna Klin. Woch.* of November 24, contains a detailed review of eighty-five cases in literature and a personal case, by F. Schopf. He concludes: Compression should be attempted in every case if possible. It may cure alone and, if not, it at least prepares the way for a collateral circulation. If an operation is finally required, total extirpation, if practicable, is the safest method to follow. It ensures best against recurrences, promotes the development of the circulation, is no more dangerous than any other method in respect to the wounds and renders rapid

recovery possible. The number of total extirpations of all kinds of aneurysms is increasing; according to Delbet's statistics, from 1875 to 1887, 320 aneurysms were treated with ligatures and 63 with total extirpation, or one extirpation to each five ligatures, but from 1887 to 1894 there were 189 ligatures to 76 extirpations, or one to two and a half ligatures.

Radical Cure of Mal Perforans.—Chipault has cured twelve out of fourteen cases by stretching the nerve, followed by cleaning out the ulceration, removing all necrotic bone and horny edges, concluding with an aseptic bandage. All were cured, but two relapsed (four months to three years). The nerve should be stretched not too far from the spot, and still not too near. Nine times it was the nervi plant. int. and ext.; once the plant. int. alone; once the collateralis int. of the great toe, and three times the saphenous ext. at the edge of the Achilles tendon. The nerve is stretched with the finger or a forceps, principally toward the distal end. He noted in the etiology: tabes, diabetes, syringomyelia and alcoholism. The evacuation of the ulcer alone will not cure, but stretching the nerve alone will accomplish it, though much more slowly. He believes that stretching the nerve is also applicable to tumors on amputation stumps, and zoster eruptions, as well as to other cutaneous affections with a nervous basis.—*Cbl. f. Chir.*, November 19.

Wounds of the Heart.—Professor Rydygier opens up the heart by a horizontal incision starting a little to the right of the sternum, and extending through it and still farther to the left, just above the third rib. The incision is then carried downward, obliquely outward to the left, including the left third, fourth and fifth ribs. The periosteum is then cautiously detached from the sternum, and the bones sawed. The triangular flap thus made is carefully raised, keeping close to the bones and detaching the muscles. The heart is thus amply exposed, while there is no danger of injuring the pleura or pericardium, and the liability of foam production is reduced to the minimum. Riedel states that in one case the air getting into the pericardium with the blood from the wound churned the blood into foam by the heart action, until it poured down over the whole chest wall. Rydygier's flap has only been tested on the cadaver.—*Vienna klin. Woch.*, November 24.

Dressing for the Umbilicus.—S. I. Kouzmine has devised a treatment for the umbilic wound that has proved extremely successful in forty-two cases. He slips an elastic band over the cord, 3 mm. thick, 9 in diameter and stretching to 3 or 4 cm., pushing it down over the cord to within a centimeter of the abdominal wall. No further ligature is required. The stump is then covered with two or three folds of plastered cloth, which hardens into a solid shield protecting the umbilicus from infection, and undisturbed by bathing the infant, etc. To prevent injury to the abdomen a strip of cotton is inserted around its lower edge, and a cloth bandage to hold it in place. The plaster is left untouched until the cord drops off, when the stump will be found mummified and aseptic.—*Semaine Méd.*, November 30.

Dangers of Lumbar Puncture.—The usually harmless lumbar puncture may lead to fatal results in persons with abnormal cerebral vascularization, the same as a cranial injury on a normal person produces a bulbar shock for a moment, which soon passes away, while the same shock in a pathologic condition may entail the most serious consequences. *Le Lyon Méd.*, reports the case of a syphilitic with abrupt, complete paraplegia, resisting all treatment for two years, when Jaboulay resolved to try lumbar puncture. Ether; 20 c.c., of a clear fluid escaped, and 10 c.c. of a 5 per cent. solution of iodine were injected. While the patient was still half drowsy from the anesthetic, the respiration suddenly ceased, although the heart and pulse were beating regularly and there was no marked cyanosis. In spite of artificial respiration, traction of the tongue, etc., it

was impossible to re-establish normal respiration, although the heart and pulse action continued normally for over an hour and did not finally cease for an hour and a half. The necropsy disclosed generalized syphilitic myelitis, with a softened focus in the left brain, no alteration noted in the medulla, liver or heart, but multiple syphilitic gummata in the right kidney.—*Presse Méd.*, November 19.

Diffuse Parenchymatous Keratitis.—Syphilis has been found the most important factor in the affection in Panas' experience, but in from 30 to 50 per cent. some other cause must be sought. It is also observed in animals, which do not have syphilis. Tuberculosis was noted in twelve out of fifty-one cases and next in the etiology, impaludism, influenza, rheumatism, gout, uterine affections and rachitism. The usual treatment was deep injection of mercuric iodid, and then potassium iodid administered internally, in tuberculous cases, deodorized iodoform in powders. Paracentesis of the anterior chamber and iridectomy, seem to act favorably in chronic cases.—*Presse Méd.*, November 19.

New Symptoms of Measles.—Meunier has noted a marked loss of weight in persons during the incubating stage of measles, when there are no symptoms as yet to indicate the disease. It is noticeable four or five days after contagion and amounts on an average, to 300 or 50 grams a day in child of 1 to four years. It may even attain 790 grams. This progressive loss of weight continues several days and seems to be independent of the age, or severity of the affection afterward. He suggests that it may prove important in indicating and isolating the disease in schools, etc.—*Gaz. hebdom. de Méd.*, 89.

Formulæ for Cuticolor Ointments and Pastes.—Rausch has been devoting much time to studying the best combinations for this purpose and testing them. He recommends the following formulæ, all for external use. The ichthyol preparations are adapted whenever an emollient and vaso-constricting effect is desired. Sublimate can be added at will, without affecting the color. 1. Cuticolor zinc ointment: Armenian red bole .03 gm., glycerin 6 drops, zinc ointment to 10 gm. 2. Una's zinc paste: Armenian bole .24 gm., glycerin 20 drops, eosin (1 to 500), 8 drops, zinc paste 40 gm. 3. Una's zinc sulphate paste: Armenian bole .24 gm., glycerin 20 drops, eosin (1 to 500) drops, paste of zinc sulphate 40 gms. 4. Una's ichthyolized zinc paste: ichthyol, 1 per cent., zinc paste 30 gm., eosin (1 to 500) 16 drops. 5. Ichthyol, 2 per cent.; zinc paste 40 gm., eosin (1 to 500), 20 drops. 6. Ichthyol, 3 per cent.; zinc paste 40 gms., eosin (1 to 500), 22 drops. 7. Ichthyol, 4 per cent.; zinc paste 40 gm., eosin (1 to 500), 40 drops. 8. Ichthyol, 5 per cent.; zinc paste 40 gm., eosin (1 to 100), 12 drops. Cuticolor gelanthum: Armenian bole .02 gm., eosin (1 to 500) 2 drops; zinc oxid 4 gm., glycerin 3 gm., gelanthum 20 gm.—*Journ. de Méd. de Paris*, November 27.

Sanguinaform.—C. S. Engel of Berlin has applied to therapeutics the physiologic fact that the red-blood corpuscles in the embryo of mammals are nucleated and peculiarly rich in hemoglobin. He procures the embryo of the pig in large quantities, fresh from the slaughter-houses, and produces a powder from the blood-forming organs, desiccated and pulverized, with two parts each lact.; a trifle ol. menth. pip., and for some cases, 2 per cent. ferrum oxydatum. This is administered, per os, three times a day, each dose, from what can be taken up on the point of a knife to half a teaspoonful. He is much gratified at the results attained, which correspond to the theoretic assumption of the value of this treatment with physiologic hemoglobin. In a boy of 7 years, the specific gravity of the blood rose from 1046 to 1057; the hemoglobin increased rapidly from 40 to 60, and finally to 75 per cent., in the course of two and a half months. His investigations were made on ten subjects, mostly chlorotic girls, and every two or three weeks the blood was carefully tested for its specific gravity, alkalinity, amount of hemoglobin, proportion of red and white corpuscles, blood plates, etc. His communication in the *Deutsche Med. Woch.* of November 24 is a theoretic and practical study of our present knowledge of the subject.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	2.00
Single Copies	10 Cents

In requesting change of address, give old as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, DECEMBER 24, 1898.

INJURY OF THE SPINAL CORD WITH SYMPTOMS
OF SYRINGOMYELIA.

When the condition of syringomyelia was first described, it was believed that the accompanying symptoms were distinctive and characteristic, and that the peculiar sensory dissociation observed was pathognomonic, but time and experience have not unqualifiedly sustained these earlier notions. It has been abundantly shown, clinically and pathologically, that the symptoms, except as to their mode of onset and course, bear no relation to the process itself or to the nature of the lesion, but rather to its situation and extent. So-called syringomyelic symptoms have been observed in association with cavities, neoplasms, hemorrhages, traumatism and other lesions of the spinal cord; and the manifestations vary in accordance with the structures involved. Most often the multipolar ganglion-cells of the anterior horns of the cervical cord are affected, so that weakness and wasting of muscles in the upper extremities result; while involvement of the adjacent pyramidal tracts gives rise to spastic phenomena; and invasion of the posterior columns is responsible for interruption of sensory impulses, tactile and muscular sensibility often escaping, while pain-sense and temperature-sense are usually impaired or lost. As stated, there is, however, no rigid invariability of the symptoms or in their distribution or extent.

An instructive case of vertebral injury, with involvement of the cervical cord, and presenting symptoms of syringomyelia, is reported by LLOYD in the Spring number of *Brain* for the present year, with some

interesting reflections on the course of the sensory tracts in the cord. A laboring man, 60 years old, had, at the age of 30, received an injury to the dorsal and cervical spine by being jammed between two canal-boats, but recovery took place after five weeks' treatment. At the age of 57 years, the man was buried in a landslide for an hour; and on returning to consciousness after twenty-four hours, the *left* arm and leg were found paralyzed. Contractures subsequently developed. The muscles of the arm and shoulder were, besides, atrophied and the seat of fibrillary contractions. Clonus was marked in the fingers, wrist and ankle on both sides, and the phenomena of so-called spinal epilepsy were readily elicited in the legs. Appreciation of pain was lost on the entire *right* side of the body, excepting the face; temperature-sensibility in the *right* lower extremity and in a small area on the anterior aspect of the right side of the chest; and tactile sensibility in the *right* leg. An angular deformity involving the seventh cervical and the first and second dorsal vertebrae was visible, as well as a depression in the lumbar region.

Death resulted from some intercurrent affection five years after the second accident. On postmortem examination, in addition to evidences of extensive fracture of the cervical vertebrae, the dura was found adherent to the body of the sixth vertebra, while an angular deformity at the junction of the fourth and fifth vertebrae compressed the cord into a ribbon at the exits of the fifth, sixth and seventh cervical roots. At the level of the third and fourth roots the dura was twice as thick posteriorly as anteriorly. On histologic examination, the greatest destruction was found at the level of the seventh cervical vertebra and on the left side, including the pyramidal, cerebellar and antero-lateral ascending tracts, the anterior and posterior horns, the anterior portion of the posterior columns and the gray and white commissures. The destruction extended across to the right side of the cord along the commissure, but in its greatest intensity did not reach the horns of the right side. There was, however, some diffuse degeneration of slight degree in the antero-lateral column of the right half of the cord, and the anterior and posterior horns were misshapen and slightly degenerated. Ascending degeneration of the left cerebellar and antero-lateral tracts could be traced to the medulla oblongata, and two well-defined streaks of degeneration in the posterior columns, the one extending from near the gray commissure backward through the postero-external column, and the other from a point in the postero-internal column at the posterior longitudinal fissure backward and outward, but not to the periphery of the cord, could be traced to the level of the pyramidal decussation. There was marked descending degeneration of the left lateral pyramidal tract throughout the cord, slight degeneration of the right pyramidal tract, slight diffuse degeneration in the posterior columns, and degeneration

in the comma-zones for a short distance downward.

It is pointed out that while no cavity had formed in the cord, the seat of the lesion, particularly in its distribution about the central canal and the central gray matter, corresponded with that observed in many cases of syringomyelia. The segmental loss of tactile sensibility confined to the right leg is considered possibly hysteric, from the absence at and above the seat of lesion of any serious involvement (such slight implication as existed being symmetric) of the postero-internal columns, through which the sensory fibers from the lower limbs pass. PRINCE, in the article on syringomyelia, in DERCUM's "Text-book on Nervous Diseases" (p. 590), cites BRUHL and CHARCOT as authority for the statement that "the loss of sensation in the arms occurs in zones, extending in a circular manner around the limbs, as in hysteria, and does not follow the anatomic distribution of the nerves in neuritis. This zone-configuration is thought to correspond with the arrangement of the spinal centers."

The thermanesthesia and the analgesia in this case are considered as pointing unerringly to the conclusion of VAN GEHUCHTEN, that in all probability pain-sense and thermic sense are transmitted through the gray matter by way of cells whose axis-cylinders become the fibers that constitute especially the antero-lateral ascending tract; and these fibers are, according to the same authority, crossed. The fibers for tactile sensibility are believed, on the contrary, to pass up the posterior columns on the same side.

USE AND ABUSE OF COCAIN.

When we reflect upon the almost universal use of this drug in medical and surgical practice it is difficult to understand that but fifteen years have elapsed since its introduction to the medical world. Even at that time it was thought by those acquainted with its uses that a new era had been opened, particularly in the realm of minor surgery, but probably its most sanguine adherents little reckoned that in so short a time it would become so well known as to escape the bounds of professional watchfulness. Its advantages in small and short surgical operations, where without its use general anesthesia would become almost imperative, has been exemplified times without number. The injection of a 0.5 per cent. solution into the deeper layers of the skin along a proposed line of incision will make that incision practically painless, and abdominal sections have been performed under this local anesthesia alone.

By its invaluable aid wonders have been accomplished in ophthalmic surgery. Previous to the introduction of cocain, when a cataract operation must perforce be performed under a general anesthesia, the operators were not at all sure but that they would find the vitreous upon the primary dressing, forced out of the wound by the retching and vomiting efforts so frequently happening after the administration of

an anesthetic; or perhaps the violence of these efforts exciting a hemorrhage into the vitreous, in either case interfering absolutely with the success of the operation.

In nose and throat practice, cocain finds its most frequent use, and we might add, abuse. Not only are the various operations along these passages facilitated by anesthetizing the mucous membranes with solutions of this drug, but other important purposes are also well served; we are able to tell if a turbinate body is congested or whether the chronic congestion has led to true fibroid hypertrophy, by noting whether or not a weak solution is able to materially reduce the size of one of these bodies; if so congestion is principally to blame, and vice versa. Suppose that we are dealing with a patient with congested turbinates, and a cocain solution is applied; contraction in these erectile tissues soon follows, and the rhinologist is then vastly better able to discover other pathologic lesions that may be situated posteriorly, while operative procedures are far more easily performed by thus enlarging the field of vision. Again, when caustic drugs, either in strong solution or in pure form, are to be applied, it is the part of humanity to relieve the patient of all possible suffering in so far as it is not inconsistent with his safety.

In acute rhinitis, by contracting the vessels of the nasal mucous membrane, the turbinate bodies are reduced in size, the nasal cavity is freely opened, and the patient much relieved; but with the wearing off of the beneficial effect of the cocain, which unfortunately takes place very quickly, the vessels become more congested and tortuous than before, and the condition is aggravated. Resort is again made to the spray, and the same farce, or rather tragedy, is again enacted.

Before we had any realization of the hidden dangers of the drug, slaves to cocain were detected in all parts of the world where this terrible servant had been introduced. The servant had again become the master and a master that demanded the very lives, by inches, of his slaves. Even in comparison with morphinism but a small proportion of cocain habitués are ever able to throw off the shackles of their tyrant, and the results of the latter drug are even more deleterious and deadly than the former. It is to be deplored that so many of our profession have yielded to its devastating influence, and all the more so that anyone, professionally or otherwise, is so easily able to replenish his supply at the nearest drug store without prescription.

Unfortunately, in the early stages of the habit, the mental faculties as a rule are greatly benefited, and more head-work, if it may be so termed, can be performed. Cases without number have been reported of this influence among professional men, physicians, lawyers and even ministers. We all remember how Dr. CONAN DOYLE makes his great hero, Sherlock

Holmes, perform his feats of reasoning only after the instillation of a few grains of cocain into his veins. As in the morphin and chloral habits, it takes progressively increasing doses of cocain to satisfy the craving, and cases of taking as high as sixty grains in twenty-four hours have been reported. Later the drug exerts a degenerative action on the nervous system, and the will-power is completely lost. Upon the other tissues the condition becomes similar to that which in children we have been pleased to term *marasmus*. As regards the histologic effect upon the various organs, many experiments have been made upon the lower animals, and we have reason to believe that similar changes take place in man. In the brain and cord there is usually a well-developed hyperemia. On microscopic examination there are found degenerative changes in the large ganglionic cells of the cord and in other large collections of these cells in various parts of the body, particularly the cardiac ganglia. SCHEPPEGRELL, who has looked into the subject rather closely, makes the following statement: "In chronic poisoning the degenerative processes are found to have advanced farther in the cells of the spinal cord and medulla, minute cavities, atrophy and hyaline degeneration of the muscular tissues; in the nerve ganglia there is fatty degeneration, minute cavities and simple atrophy; in the liver atrophy of the hepatic cells is present. The vascular system is most affected in the spinal cord, there being cellular proliferation and hyaline degeneration of the coats. In the heart and liver an atrophic condition of the tissue is found, also a swelling of the endothelium of the capillaries of the cardiac ganglia."

Acute cases of poisoning are by no means uncommon, as every rhinologist will testify. Especially are the symptoms liable to follow the spraying of the nose with the usual strength used, 5 per cent., as a preliminary to examination and treatment. The nasal mucous membrane having a greater absorbing power than that of the mouth and pharynx, toxic symptoms are more apt to follow applications to the former. In mild cases of poisoning, the pupils dilate, the pulse becomes slow, the skin exhibits a marked pallor, the patient is often loud and boisterous in his conversation; in more pronounced cases, the face becomes cyanosed, the pulse rapid and thready, and syncope may supervene. Finally coma, with stertorous respiration and abolition of the reflexes may come on with the most startling rapidity, followed closely by dissolution. The amount of the drug appears to have little influence in the production of mild or grave symptoms, idiosyncrasy here being of the greatest importance. The time elapsing between the application of the solution and the establishment of toxic symptoms also varies within wide limits.

One word as to the substitution of drug habits. Attempts have frequently been made to cure morphinism by the use of cocain, and vice versa, this

either on the advice of physicians or the victim attempting to take the cure into his own hands. This is not to be countenanced for a moment, in that the habitué becomes a slave to both, and the breaking down of his nervous system occurs even more rapidly than before. Many persons become victims through the pernicious habit of taking snuff. Probably all preparations of this contain cocain in larger or smaller quantities, and the physician may often be put upon the right track by obtaining the history of such a habit.

SCHEPPEGRELL, through his residence in New Orleans, has been enabled to add to the literature a peculiar phase of the cocain habit. He states that among the southern negroes, not a few of them draw up crystals of some salt of cocain into the nose. The object of this is not to obtain a free breathing space, but on account of the exhilaration a small quantity produces when taken in this manner.

Lastly, we must remember the many blessings that the proper use of cocain has bestowed upon mankind, at the time not forgetting that we are dealing with a two-edged sword. We should never put the drug into the hands of the patient himself. We should endeavor to find some means of preventing its dispensation by druggists without a prescription by a qualified physician. We should not in our private offices be too prone to apply it indiscriminately to all cases where a little suffering is to be borne. When it does become necessary to resort to its use in private practice, we should not allow our patient to know what drug is being used. With these restrictions, cocain has the greatest power to yield good results, and may in time become an unmixed blessing and regain the place in the profession that of late years it seems to have lost.

ALCOHOLISM IN FRANCE.

MR. ARCHDALL REID, in a publication of his which has been recently widely quoted, considers alcohol as working out a benefit to the race by exerting a selective action on degeneracy, and thus in time producing a racial immunity to its own effects. There may be a grain of truth in this opinion, but in some respects it is open to question, and it does not so fully justify the conclusion obviously deduced by many, and apparently so intended by the author, that it is rather a good thing than otherwise for the race. If it acts in this way, so, it may be said, do tuberculosis, syphilis and other pests of civilization, which also cull out the physically and otherwise defective, and to the extent that they leave only the more resistant and prudent, may be said to improve the race average, and also to develop in time a certain degree of immunity to their attacks. That alcohol can be said to really act in a similarly remotely beneficial way, while directly and immediately disastrous in its effects, is far from being an established truth, either sociologically or physiologically, and as an abstract truth it is still more open

to dispute. We may speak approvingly of the fool killer as serving a useful purpose, but he becomes a very serious functionary if the general population, as a distinguished Briton once said of his countrymen, are mostly fools.

It is of interest in this connection to note the spread of the agitation against alcohol in countries, where, if a real immunity could be produced by long-continued usage, it ought now to exist. In our own country and in Great Britain the question is comparatively an old one, and there is little doubt that the conditions here and there are better in this regard than they formerly were. Most people, however, would be inclined, from a survey of the facts, to attribute whatever good has resulted rather to a public sentiment in favor of temperance than to any immunity derived indirectly through the vices of ancestors. In continental Europe, the general interest in the medical and sociologic aspects of the alcohol question, judging from the active public efforts in this direction, is of more recent date, but it seems to be increasing, and may be taken, in some measure, as an index of the greater spread of the evils of alcoholic excess. In France, a country that should show an immunity if any can, the conditions appear to be serious enough and to amply justify apprehensions of national disaster from alcoholic degeneracy. According to a recent paper by Prof. M. DEBOVE in the *Presse Médicale* of November 16, the consumption of alcoholic drinks, calculated in figures of absolute alcohol (100 per cent.), is at present 14 liters per inhabitant, as compared with 10.5 liters in Germany, 9.25 in Great Britain and 6.10 in the United States. If distilled liquors only are included, as in a recent thesis by M. RUYSEN, quoted by DEBOVE, the amount is 4.54 liters per head as compared with 2.85 liters in this country. The figures he gives are the more significant when comparisons of recent and former years are offered, and we see that the consumption of alcohol in distilled spirits per head has risen in France from 1.1 liter in 1830, and has decreased in this country from 5.75 liters in 1860 to the present figure of 2.85. France, a country where alcohol in the form of wines and other fermented liquors has been almost universal and which ought reasonably to have thus acquired an immunity, if such were possible, has taken more and more to stronger drinks till it now leads the list, while this country, which a few decades ago had a still higher ratio, has fallen back in their usage to nearly the lowest figure, and is well down toward the minimum in the usage of all forms of alcohol-containing beverages. The number of cabarets in France has increased from 281,000 in 1830 to 500,000 in 1897, and indeed in some departments there appears to be one dramshop to every twenty or thirty adult inhabitants. New York and Chicago, with their numerous enough saloons, appear very moderately equipped in this regard when

compared to Paris with its 33,000 cabarets, or one on an average to every three or four houses. M. DEBOVE sarcastically says, in view of the rapid spread of these establishments, that he does not despair of yet seeing street-cars turned into ambulant saloons and thus spreading throughout Paris the benefits of alcoholism.

It would seem that there might be some error in Professor DEBOVE's figures; they certainly appear extreme, but we have no means of contradicting them. If correct, the economic aspects of this overgrown industry, if such it can be styled, ought to stir up French statesmen and legislators. France certainly appears to be well in the way of obtaining all the "benefits of alcoholism" to the full satisfaction of ARCHDALL REID and others of his class who can discover these beneficial effects.

While France seems to be in the lead in this regard, other European countries are also advancing in the same line. Belgium appears to be one of these, and some years ago similar complaints were uttered by a distinguished Austrian alienist in regard to the spread of the use of stronger alcoholics in southern Europe. The anti-alcohol congresses that have been held within the last few years and have been attended by some of the highest medical authorities, are a sign of the times that the need of some check is needed for the increasing alcoholic consumption. The movers in this work are not fanatical prohibitionists or even, as a rule, advocates of total abstinence at the present time—they are chiefly scientific medical men who can see the evils they wish to check. In a country like France, that seems just now, to use a colloquialism, to be going the full pace, there is certainly room for their best efforts.

THE ARMY MEDICAL DEPARTMENT OF THE FUTURE.

Under the above caption, in our issue of December 3 last, we suggested the likelihood of a large increase of the personnel of the Medical Department of the Army in the immediate future. We considered that for the Regular Army required by the United States, the present strength of the Medical Department, 192 officers, would have to be increased to at least 450 by the appointment of 258 medical men to fill original vacancies. This we regarded as the very minimum of needful expansion. Since then, three bills providing for the reorganization of the army have been introduced into the Congress of the United States. The precise wording of these bills is given in another column. It suffices for our present purpose to say that one provides for an increase of 404 medical officers, and each of the others for an increase of 309, making the total of the one 598, and of the others 501. It is evident that some action will be taken by Congress to increase and reorganize the regular army, so that the volunteer troops may be relieved from service and returned to their homes; and it seems probable that

this action will involve a large addition to the present medical force. This is the point which we desire to bring to the notice of the younger members of the Association, that those of them who have military aspirations may not be taken unawares by the announcement of the convention of an examining board to fill vacancies in the corps. Army medical appointments have been made by competitive examination since the days of the Revolution. In 1775 the Provincial Congress of Massachusetts Bay required each candidate for a position in the Medical Department to be subjected to a close examination by qualified medical men, and there was nothing *pro forma* in the work of that early board, for it is on record that eight out of fourteen candidates were rejected for failure to come up to the standard. The system then instituted has never ceased to be the rule. In the coming expansion of the corps, it is not likely that appointments will be made without this examination. In fact, all the bills now before Congress provide for the examinations now required by law.

No action will probably be taken by the Surgeon-General of the Army looking to the selection of the best men for the new position until these positions have an actual existence by legislation; but medical men desirous of filling them may do much in the way of special preparation to meet examining boards, if they recognize the likelihood of the speedy appointment of such boards. We know from the "Circular of Information for Candidates seeking Appointment in the Medical Corps of the United States Army," that applications for permission to appear for examination are in order at all times. This circular, issued from time to time by the Surgeon-General of the Army, gives the Constitution of the Medical Department at the date of its issue, and states the pay and emoluments and the duties and privileges of army medical officers, the method of making application and the manner and scope of the examination to which candidates are subjected, illustrating the general character of the latter by a series of questions on the various subjects taken from the records of a recently convened board.

At this present writing, the Chairman of the Military Committee of the House of Representatives is reported as having stated his belief that a bill reorganizing the army will be passed at a very early date. Our young friends should be prepared for prompt action by the Surgeon-General of the Army on the passage of this bill.

CORRESPONDENCE.

Stammering.

CORTLAND, N. Y., Dec. 13, 1898.

To the Editor:—In a late number of the JOURNAL there was a note as to the cause of stammering that startled those of your readers who heard the after-dinner speech of Mr. Henry Guy Carleton. To see the rich jokes of this excruciatingly

funny stammerer presented as an item of medical interest is too much. But when we see it this week copied into the *Philadelphia Medical Journal*, sandwiched in between articles on the pure flour law and under-average life risks, the matter becomes serious. Would it not be well to mention that his comma bacillus of stammering is not to be taken so seriously as it reads? Yours respectfully, F. W. HIGGINS, M.D.

ASSOCIATION NEWS.

Section on Laryngology and Otology.—The program for the Section of Laryngology and Otology has been filled, and no more papers can be accepted for the Columbus meeting in June, 1899.

BOOK NOTICES.

Physician's Visiting List for 1899. Philadelphia: P. Blakiston's Sons & Co. 1898. Leather cover, \$1; plain binding, \$0.75.

This is the forty-eighth year of the publication of this handy visiting list, which will be useful to any physician. In contents, besides the blank leaves, a calendar, tables of signs, weights and measures, dose table and a "new complete table for calculating the period of utero-gestation."

Medical Record Visiting List for 1899. New revised edition. Leather. New York: Wm. Wood & Co. 1898.

In this edition the matter useful in emergencies has been increased, an important change being "in the list of both apothecaries' and decimal systems, and the indication of such as are official." There are also the uses tables concerning matters the physician often wishes to refer to, as weights, measures, solutions, etc.

PUBLIC HEALTH.

Technic Instruction for Religious Orders.—The recent French Catholic Medical Congress passed resolutions urging the training of all sisters of charity in the professional care of the sick and the instruction of the students in seminaries and theologic colleges, in practical hygiene, by a physician.—*Jour. des Sci. Méd. de Lille*, November 26.

Influenzal Prevalence.—A mild form of la grippe has been reported by many physicians of New York City and vicinity, a few cases having appeared as early as the middle of November. A large proportion of the cases have taken on the form of an acute coryza with soreness of the throat. The attack almost invariably begins with a chill, and headache and pains in the limbs.

New York State Pathologic Laboratory.—The ninth annual report of the New York State Commission in Lunacy, just issued, contains a full report on the methods and principles underlying the pathologic work of the State hospitals in the central laboratory in New York City. According to the *Charities Review*, November, this report "should receive careful consideration, for it not only develops methods of investigation, but presents a new view of the pathology on insanity, which by common admission is less perfectly understood than any form of disease afflicting the human race; and, if any hope of alleviating this curse is held out, in a better understanding of its nature and prevention, no possible means should be withheld, or no lack of encouragement toward its thorough investigation." Dr. Van Gieson, the director of the institute, is clear and explicit in his demonstrations and deductions, and can not well be misunderstood.—*Medical News*.

Scallops in Sewage Waters.—According to the *Medical News* for December 3, Fairhaven, Conn., has a large industry in shell-fish which is being injured by sewage pollution. So large have become the quantities of factory refuse and sewage that pour

into the docks that pleasure boats no longer anchor at that point. When the New York Yacht Club gave this as a reason for omitting its annual visits it was laughed at, but now the citizens appreciate that the yacht owners discovered a condition which is becoming serious. When the Vineyard steamers went out this summer there was a trail of stench in their wake as they stirred the water with their paddles, which demonstrated how polluted the river is with filth. Business at the Fairhaven bath-houses has fallen off, for it is only at high tide, and often not then, that the water is sufficiently clear to tempt a bather. Scallops taken in the upper harbor have caused fever among those who have eaten them, and physicians have declared that the shell-fish which live in the mud on the shore are dangerous to eat on account of the sewage. Many are agreed that there are things more serious than high taxes, and a menace to the health of the community is not to be lightly regarded.

Epileptic Colony in New Jersey.—Under an enactment passed in 1898, an "epileptic village" is about to be inaugurated in the southern part of New Jersey. The act defines that this colony shall be governed by six managers, constituting a non-partisan board, having a three-year tenure. This board is instructed to select a suitably-located site, provided the cost of the same with the buildings on it shall not exceed \$15,000. The law further requires that all plans for improvements to the property shall be submitted to and approved by the governor of the State. It is understood that a suitable site, consisting of about two hundred acres of land in the central part of the State, near Princeton, has been secured, that there are some good houses on the place, and that it is the intention of the managers to get enough of these buildings in condition to receive about twenty patients during the present year. Patients are admitted on a certificate signed by at least two freeholders of the town or township in which the applicant resides, which certificate must be attested before a magistrate. Freeholders in New Jersey exercise about the same powers and duties relative to charitable work as is exercised by superintendents and overseers of the poor in New York. The certificate made by the freeholders must also be certified to under oath by at two physicians, who must set forth the fact that the patient is an epileptic.—*Charities Review*, December.

Diet for Laboring Men.—Secretary Wilson of the Agricultural Department has been engaged in an investigation for the purpose of throwing light upon the most suitable varieties of food for laborers, mechanics and others whose daily work involves the expenditure of great muscular efforts. His agents in this research have studied the dietary of athletes and others, the amount and variety of whose food was measured and regular. Extensive examinations have been made on farms, in the shops and the factories, but the results there were not so satisfactory as at Yale, Harvard and other places, where better facilities were afforded for making tests. Agents of the Department were present at both New Haven and Cambridge while the crews of those universities were in training for their big rowing match last spring, and kept accounts of the amount and variety of food furnished to the men. There is no absolute rule as to the diet of the athletes, and trainers of men preparing for feats of strength and endurance have widely varying ideas on this subject. Investigations are to be carried on in other lines, with the idea in view of finding out what foods are the most nutritive for hard-working men. Experiments with bread and cereals have been carried on at the University of Maine, and at the University of Tennessee digestive experiments were made on the students. Interest in the nutrition investigations being made by the Agricultural Department is spreading all over the country. Secretary Wilson states that among the gratifying evidences of this fact is the recent appointment of one of his agents as a consulting expert to the

Lunacy Commission of the State of New York on the food and diet of the insane. In connection with its other duties this commission is charged with prescribing the diet for the inmates of the asylums for the insane throughout the State. The Department of Health of the City of New York is arranging to issue circulars of practical information regarding the nutritive value and preparation of foods for general distribution in that city.

Kings County Hospital, New York.—This important institution, located at Flatbush, Long Island, is the subject of a special official report by Commissioner T. G. Bergen. This hospital for the poor of Kings county has in former years been the scene of disgraceful overcrowding and other scandal, growing out of years of political jobbery. Under the management of Dr. J. T. Duryea, medical superintendent for the past two years, important improvements have taken place, not only in the appearance, but in the accommodations of the place. Not only have all the wards been renovated and better furnished and supplied and the operating-room established, but a special home and rooms for trained nurses are already furnished, as well as a house for the resident physician and special rooms for the members of the medical staff. At the present time the presence of the professional nurses in their uniforms, with junior nurses or pupils aiding them and learning their profession, the improved condition of the quarters for the medical staff, and the opportunities furnished for instruction to medical men, graduates of medical schools, are a mark of an up-to-date system. For the first time in its history this hospital is now making a return to the medical world for the benefit of science and, therefore, for the good of humanity, for all the sums which in recent years have been spent unscientifically upon its wretched maintenance. It is proposed, with the additional sum of \$100,000, granted by the Board of Estimate of 1898, to furnish additional wings to the main building for the accommodation of two hundred or more patients, for a better home and resting-place for all the nurses, away from their patients when off duty, and possibly for better accommodations for the idiots and feeble-minded and for convalescents, and also to create an amphitheater for the purpose of clinical instruction. In this way this hospital may yet become a credit to the people and a blessing to the sick poor of the Brooklyn Borough. Nearly 680 patients are now under treatment at this hospital, very many of these afflicted with diseases which prevented their admission into other hospitals of the city.

SOCIETY NEWS.

Washington Microscopical Society.—At the regular meeting of the Washington Microscopical Society, held December 13, a joint paper was read by Drs. George T. Howland and Henry A. Robbins, entitled "The Gonococcus Neisser," and the different methods of staining.

Cincinnati Society for Original Research.—At the regular meeting, December 8, the following program was given: Dr. Sattler, "Anatomic Basis of Temporal Neuralgia;" Professor Edwards, "Plans of the Biologic Laboratory of Cunningham Hall;" election of Officers.

Association of the French Medical Press.—An international congress of the medical press is being discussed by this Association, and efforts are under way to have it organized as a special Section of the International Medical Congress of 1900. If not found feasible, it is proposed to hold it as an autonomous congress. A congress of medical deontology is also under discussion, and the organization of a medical club in Paris.—*Presse Méd.*, November 12.

Northwestern Ohio Medical Association.—The fifty-fourth meeting held at Lima, Ohio, December 8 and 9, 1898, was the largest

and one of the most interesting meetings of the association. Twenty new members were admitted and 122 applications for membership received. The next meeting will be at Findlay, Ohio, in December 1899. The following are officers: R. E. Jones, Gower, president; W. K. Dickey, Toledo, first vice-president; B. S. Leonard, West Liberty, second vice-president; J. P. Baker, Findlay, secretary; T. M. Gehrett, Deshler, assistant secretary and treasurer.

American Physiological Society.—According to *Science*, November 4, a meeting of the American Society of Naturalists will be held in New York, December 28 to 30, at which arrangements will be made for sessions of a number of affiliated scientific organizations. Among these, it may be stated that the American Physiological Society and the American Psychological Association will meet on Wednesday, Thursday and Friday, and probably the same days will be chosen for the American Morphological Society, the Society for Plant Morphology and Physiology, and the Association of American Anatomists. The Section of Anthropology of the American Association will meet on Tuesday, followed on Wednesday by the American Folk-Lore Society.

Washington Chemical Society.—At the recent meeting of the Washington section of the American Chemical Society, held at the Cosmos Club, Dr. E. A. DeSchweinetz of the Columbian Medical School, read a paper on the "Estimation of Nicotin," and reported his past investigations and experiments with the curative serum for hog cholera. He also exhibited liquid air, which he served with a ladle and demonstrated its wonderful and interesting properties.

Society of Ophthalmologists and Otologists.—The November meeting of the Society of Washington Ophthalmologists and Otologists was held at the residence of Dr. J. H. Bryan, Dr. Swan M. Burnette, president, in the chair. Dr. Bryan read a paper entitled "Chronic inflammation of the Middle Ear." He discussed, at some length, the differential diagnosis, and pointed out the particular class of cases which should and those which should not receive operative interference. Dr. Suter read a paper on the "Twisting Power of Cylindric Lenses." An interesting discussion followed both subjects, and was participated in by Drs. Burnette, Wells, Richardson, Muncaster and Belt.

Philadelphia County Medical Society.—At the last stated meeting of the Philadelphia County Medical Society, Dr. Lawrence Flick read a paper on the subject of "Contagion; Its Meaning and Sanitation." In the paper the speaker first introduced the philology of the word "contagion," after which he cited the definition as expressed by different medical writers. Speaking further on the subject, Dr. Flick thought that the word "contagion" should include the word "infectious." Drs. A. A. Eshner and Solis Cohen both dissented from the view as expressed by Dr. Flick, and held to the opinion that the word "contagion" should be used in rather the restrictive sense, while the word "infectious" should be used more broadly and include the word "contagion." Dr. H. Ferree Witmer presented an unusual case of aphasia affecting a lad about 15 years of age. Suitable charts and diagrams were also exhibited to show the locality of the lesion. Dr. A. J. Downes read a paper on the "Bottini Operation for Enlargement of Prostate Gland," and exhibited the instruments and battery necessary to complete the operation. A case in which an aged person had been treated for this affliction with distressing symptoms, at the hands of the speaker, had shown a wonderful improvement. Only five minutes are consumed in the operation, which seemed relatively free from danger.

International Congress of 1900.—Dr. Lannelongue, chairman of the Organizing Committee of this medical congress, has announced that the time for holding the sessions has been fixed for Aug. 2 to 9, 1900. The entrance fee, amounting to 25 francs, can either be sent to the general manager at Paris or to the committees who are acting in foreign countries. Every subscriber will receive a document showing the extent and arrangement of the Section in which he is interested. The congress is divided into five Sections: 1. Biology: *a*, anatomy, descriptive and comparative; *b*, histology, embryology, teratology; *c*, physiology, physical and biologic chemistry; and *d*, anthro-

pology. 2. Medicine: *a*, general and experimental pathology; *b*, bacteriology and parasitology; *c*, pathologic anatomy; *d*, visceral pathology; *e*, medical diseases of children; *f*, therapeutics and pharmacology; *g*, nervous diseases; *h*, mental diseases; and *i*, dermatology and syphilology. 3. Surgery: *a*, general surgery; *b*, surgical diseases of children; *c*, surgery of the urinary organs; *d*, ophthalmology; *e*, laryngology and rhinology; and *f*, otology. 4. Obstetrics and gynecology. 5. State Medicine: *a*, hygiene, sanitary medicine and epidemiology; *b*, forensic medicine; and *c*, military medicine and surgery, naval medicine and surgery, and colonial medicine. Two general meetings will be held; one on the opening day and the other at the end. Only those members nominated and invited by the Committee will be able to read papers. All proposals relative to the work of the congress must be handed in to the Committee before May 1, 1900.—London *Lancet*, November 26.

Washington Obstetrical and Gynecological Society.—The two hundred and eighty ninth meeting of the society was held December 2, at the residence of Dr. Joseph Taber Johnson. Dr. Bovee presented two Fallopian tubes which he had removed. In either tube hematosalpinx and pyosalpinx was found, the blood tumor occupying the tubes nearest the uterus, while the pus cavity occupied the fimbriated portion. Dr. J. T. Johnson presented two large, fibroid uteri, which he had recently removed. The first was removed from a white woman, aged 58 years, who gave the following history: Eight years ago she consulted Dr. Murphy at Columbia Hospital, and he performed an abdominal section but declined to remove the tumor, on the ground that it was not a suitable case for operation. She applied to Dr. Johnson at the Georgetown University Hospital two weeks ago, who successfully removed the growth. The growth presented a large polypus in the interior of the uterus. The second was removed from a white woman, aged 38 years. This was a large, pedunculated fibroid which grew in the broad ligament. As the uterus was found to be diseased, that was also removed. Both patients made an excellent recovery. The paper of the evening was read by Dr. Samuel S. Adams, on the diagnosis of tubercular meningitis in infants. Dr. Adams discussed particularly the question of diagnosis and pathology. He gave the history of three interesting cases, which he had recently seen in consultation with other members of the society. The patients died, and he regretted that no postmortem was permitted. The discussion was opened by Dr. E. E. Morse, and further participated in by Drs. Adams, Smith, H. L. E. Johnson, Winter, Cook and Acker. Dr. D. W. Prentiss gave the history of a case of syphilitic fever. No history of specific character could be obtained in the beginning of the attack. The patient had chills and fever daily. Finally, a suspicious sore throat suggested syphilis. Iodid of potash and protiodid of mercury promptly cured. The chart showed daily fever, often high, of a typical, regular character, but no corresponding increase of pulse.

Washington Medical Society.—At the meeting of the society held November 30, Dr. William C. Woodward read a resolution of regret on the death of Dr. Charles M. Hammett, which was formally adopted. Dr. Dallas Bache, U. S. A., and Dr. Wm. H. Gardiner were elected members by invitation. Dr. Maues presented a case of calculus pyelonephritis and calculi in the gall-bladder, with intermittent fever. The patient had been a sufferer for many years and at one time was supposed to have been suffering from peritonitis, and on another occasion was supposed to be in labor. Repeated urinary examinations showed negative results. Operated on for ovarian disease, the tubes and ovaries were removed. The patient had four attacks of renal colic and subsequently pus was found in the urine. Postmortem showed a large calculus in the left kidney and three calculi in the gall bladder. Dr. Glazebrook presented two kidneys and gave following history: The patient, aged 41 years, suffered from inguinal hernia, urethritis, stricture and rupture of the urethra; urethra sacral fistula, cystitis, retention and calculus. The stone was crushed and removed per urethra. Postmortem showed the left kidney weighed one ounce; urethra fibrans. Right kidney weighed fifteen and one half ounces. The ureter contained a large calculus and was distended from that point to the kidney. Section of the kidney showed sloughing and infarctions. Dr. W. W. Johnston read a paper on the differential diagnosis of disease characterized by regular intermittent fever. He said, that as a rule disease accompanied with chill, fever and sweating is usually assumed to be malarial, in a malarial region. The following of such a rule is often the source of error. He mentioned the following fevers which presented similar symptoms: malaria, hepatic, ulcerative endocarditis, vegetative endocarditis, rheumatic, acute tuberculosis and syphilitic. In malarial, the fever begins with chill, and the temperature is at its

height in four or five hours, followed by sudden sweat; secretion of urea is increased. Where the initial attack or the three stages continue for less than ten or more than twelve hours, diagnosis is doubtful. The spleen is usually enlarged and the skin sallow. Finding the presence of the plasmodium confirms the diagnosis. In hepatic fever there is suppurative or inflammation of the bile ducts; chill, no prodromes, irregular course; chill usually in afternoon or evening. Rise of temperature begins with chill. Sweating is least constant, usually short; urea decreased for two or three days between fever; no pain; no icterus; no physical signs, except biliverdin in the urine. Diagnosis is by exclusion and by sudden cessation. In endocarditis, one of the most characteristic symptoms is intermittent fever, chill at no fixed hour, highest evening temperature 102 degrees, followed by sweating; pulse rapid; exhaustion marked; interval of a day between fever; leucocytosis; organisms in blood; results fatal, embolic symptoms. In rheumatic fever there is chill every day, never exhausted, and stiff joints. In one case Dr. Osler noted the presence of small subcutaneous nodules on the legs. Salicylate of soda cures. Quinin is useless. In tuberculosis, fever is first intermittent, then remittent and finally intermittent; chill at midday; flushing of face; loss of flesh. In syphilitic fever, daily pain, daily fever, often high, but no corresponding increase of pulse; previous history.

At the meeting held December 14, the president, Dr. Samuel C. Busey read his annual address entitled "The History and Progress of Sanitation of the City of Washington and the Efforts of the Medical Profession in Relation Thereto." Dr. Busey described the original city as laid out, and referred to its hygienic and anti-hygienic features; the different water-courses and streams, swamps and lowlands; he referred to the gradual growth of the city and the different acts of Congress regulating its government; the introduction of Potomac water in 1859; the beginning of sewer construction in 1810; and described its evolution. He gave an interesting account of the first organized effort of sanitation, which occurred in 1819, in the appointment of a health officer, whose duty it was to report nuisances to the mayor; culminating in the present health laws of the District as aided and modified by the efforts of the Medical Society. He also referred to the evolution and growth of the city hospital system, and closed his remarks by showing the effect of sanitation in lessening the prevalence of contagious diseases and its influence particularly in lessening a number of cases of typhoid fever in the District.

NECROLOGY.

SAMUEL DECKER, M.D., College of Physicians and Surgeons, New York, 1867, of Griffin Corners, N. Y., died December 6, aged 59 years.

EDWARDS HALL, M.D., Albany, N. Y., 1844, died December 10, at his home in New York, where he was long and favorably known as a faithful family physician.

ALBIN J. FULDA, M.D., of New York, who had been in poor health for several years, died there December 9. He served during the Civil War as surgeon of the Forty-fifth New York Volunteer Infantry.

SOLOMON P. CAHEN, M.D., New York City, died of pneumonia, December 6. Born in Germany in 1895, he came to New York in 1860, returning to Germany in 1864, where he later was graduated in medicine from the University of Leipzig.

GEORGE W. BAKER, M.D., Brooklyn, N. Y., died December 5. He was born in 1837, received the degree of M.D. from the College of Physicians and Surgeons, New York City. During the Civil War he enlisted in the medical corps, and was soon assigned to a hospital in Washington, where he served for three years.

L. CHAPMAN SMITH, M.D., New York University, 1878, died at his home in Brooklyn, N. Y., December 9. After receiving his dental diploma he began the study of medicine and after his graduation, took up the study of pharmacy. He was 45 years old and a member of the Kings County Medical Society. A wife and two daughters survive him.

GOVERNEUR MATHER SMITH, M.D., College of Physicians and Surgeons, New York, 1855, died in that city December 8. He was a son of the late Prof. Joseph Mather Smith of the above college and inherited his literary as well as humanita-

rian impulses. His name was well known in hospital work and benevolent institutions. He was unmarried.

HENRY CAMPBELL DOUGHTY, M.D., Augusta, Ga., died at his home December 4, of consumption. He was demonstrator of anatomy in the Medical College of Georgia, and in addition to his work in surgery gave a great deal of attention to chemistry and bacteriology. He was but 26 years old.

NATHAN SHERWOOD KING, M.D., of Yonkers, N. Y., died at his home, December 11, of pneumonia. He was born in 1824 at Fishkill, and was graduated from Williams College in 1849 and from the College of Physicians and Surgeons three years later. He leaves a wife and one married daughter.

JOSEPH W. MARSEE, M.D., Indianapolis, Ind., Dean of the Indiana Medical College, died December 3, after an illness of two days, aged 50 years. His connection with the Indiana Medical College began twenty-three years ago, when he became demonstrator of anatomy, later succeeding to one of the chairs of surgery, and six years ago to the office of Dean.

J. G. CUNNINGHAM, M.D., Kittanning, Pa., died December 12. He was a member of the County, State and AMERICAN MEDICAL ASSOCIATION, and of the G. A. R. and Masonic bodies, and a graduate of Jefferson, class of 1867.

A. C. MORRIS CHESTON, M.D., West River, Md. December 1.

C. M. Deitrich, M.D., Galesburg, Mo., December 8.

Daniel Dupree, M.D., Dallas, Texas, November 25, aged 77 years.

Thomas D. Wright, M.D., Preston, N. Y., aged 81 years.

E. B. Fleece, M.D., Wildwood, Fla., November 30.

Hosea A. Hamilton, M.D., Oneonta, N. Y., December 6.

J. B. Hanaford, M.D., Apopka, R. I., December 6, aged 59 years.

George Z. Higgins, M.D., Strong, Maine, December 11, aged 66 years.

J. W. Hill, M.D., Knoxville, Tenn., December 4.

Francis Johnson, M.D., Pawtucket, R. I., November 27, aged 65 years.

J. L. Jones, M.D., New Middletown, Tenn., December 4.

L. Metzger, M.D., Brooklyn, N. Y., December 4, aged 35 years.

S. R. Millington, M.D., Poland, N. Y., November 28, aged 72 years.

Henry Ostrom, M.D., Alton, N. Y., December 8, aged 73 years.

John Parr, M.D., Buel, N. Y., December 7.

Martin Payne, M.D., Portland, Ore., December 2, aged 62 years.

Albert J. Philips, M.D., Baltimore, Md., November 24, aged 44 years.

D. T. Porter, M.D., Memphis, Tenn., December 2, aged 72 years.

Leander Seaton, M.D., Stauffer, Pa., December 11, aged 40 years.

John I. Sherwood, M.D., Covington, Tenn., December 2, aged 66 years.

Norman T. Shobe, M.D., Indianapolis, Ind., December 1, aged 22 years.

William S. Stevens, M.D., Augusta, Ga., November 29.

E. M. Stillman, M.D., Andover, N. Y., December 6, aged 57 years.

F. E. Strong, M.D., Lancaster, Wis., December 13, aged 40 years.

S. C. Warner, M.D., Ceres, Va., December 5.

J. A. W. Wegforth, M.D., El Paso, Texas, December 9, aged 35 years.

DEATHS ABROAD.

SIR WILLIAM JENNER, the distinguished pathologist and physician in ordinary to the Queen and the Prince of Wales, died December 12. He was born in 1815 and was educated at University College, London, in which institution he became professor of pathologic anatomy in 1848. He was president of the Royal College of Physicians from 1881 to 1889, when he retired from the practice of his profession. He was the first person to establish, beyond dispute, the difference between typhus and typhoid fevers. He was appointed physician extraordinary to the Queen on the death of Dr. Baly, in 1861, and the next year was gazetted physician in ordinary to Her Majesty, receiving the same preferment in 1863 in the household of the Prince of Wales. He attended the Prince Consort during his last illness. It was in recognition of his services during the severe illness of the Prince in 1871 that he was made Knight Commander of the Bath. He was created a baronet in 1868. He wrote numerous papers on fever, the acute specific diseases, diphtheria, diseases of children and diseases of the heart, lungs and skin. Among his published books are a treatise on diphtheria, and "The Identity or Non-Identity of Typhus or Typhoid Fevers."

H. A. PILLIET, M.D., Paris, aged 37 years. Seldom has so brief a career seen such an amount of scientific work accomplished. His constant co-operation on the staff of the *Progress Médicale* and of the *Tribune Médicale*, and as professor in the training schools for nurses, did not interfere with his abstract scientific labors, studies of the liver in infective diseases, toxic gastritis, muscles of the bladder and uterus, etc. He prepared for any work of this kind on an organ by an exhaustive study of the normal organ in man and animals, before turning to the pathologic conditions.

MISCELLANY.

Betain Hydrochlorate vs. Tetanic Toxin.—Roger and Josué announce that one centigram of betain hydrochlorate will neutralize, completely, one drop of tetanus toxin in experiments on guinea-pigs, and merely diminish the effects of two drops of toxin, thus establishing the limits of its neutralizing action. —*Semaine Méd.*, November 30.

Protracted Grippe.—Tilaloff has observed several cases of grippe lasting several months. In three cases there was continuous slight fever for five months, and in two, intermittent relapses, transient, but occurring at intervals for several years. Change of climate is required for this chronic grippe. —*Presse Méd.*, November 26.

Edema of the Larynx.—The *Rev. Hebd. de Laryng.* for November 19 describes two cases of edema of the larynx, probably of angioneurotic origin, one due to the menopause, treated with leeches, sodium salicylate and sodium iodid, gradually diminishing during several months, till final recovery. The other commenced abruptly in a young man after a simple stroll on the seashore so violently that intubation was required at once. The patient was out of danger the same evening.

Ascending Neuritis.—Marinesco concludes a histologic study of this rare affection with the statement that the most frequent if not the only cause is a local affection. If there is much tendency to spread, the agents of the infection pass by means of the lymphatic spaces in the nerve to the spinal cord; that is, a spinal-cord phase supplements the neuritic phase. The destruction of a certain number of nerve-fibers by the microbe and its toxins may affect the center even before the toxic substance has reached the spinal cord. If, on the other hand, the poison is very diffusible, the central lesions are marked before there are manifest lesions in the nerves, as happens with nicotine injected into a peripheral nerve. —*Presse Méd.*, November 23.

The Pancreas in Diabetes.—Lancereaux asserts that a certain form of diabetes, *diabète maigre*, is necessarily connected with every profound alteration of the gland, and that the other forms of diabetes may be due to a material disorder or merely a functional disturbance in the innervation. Glycosuric diabetes is therefore no longer a distinct disease, but, similarly to albuminuria in relation to the kidneys, is a syndrome subordinate to a material disturbance of the pancreas or to mere disturbance of the innervation. —*Bull. de l'Acad. de Méd.*, November 15.

Osteomalacia.—F. Schnell has observed thirty-two cases at Würzburg: one recovered spontaneously; sixteen received medical treatment alone and eleven surgical after the former had failed. He classifies them as progressive and tardy. The progressive form appears early and has no remissions. The tardy form was observed in multiparæ, with exacerbations during pregnancy and remissions in the intervals. Phosphorus and cod-liver oil proved the most effective medical treatment, diminishing the pain. Castration proved successful, not only at first, but in its permanent results. The ovaries in the fourteen cases examined were degenerated in proportion to the severity of the affection, the stroma transformed into fibrillary connective tissue, with a tendency to hyalin degeneration of the vascular apparatus.

Carrion's Disease.—The October numbers of the *Crónica Médica* of Lima are devoted each year to a discussion of this disease, better known as Peruvian verruga and Oroya fever, and to a eulogy of the devoted young doctor, D. A. Carrion, who was making a comprehensive study of these supposedly separate endemic diseases, and become convinced of their identity. To demonstrate it he inoculated himself with blood from a patient with verruga at the Hospital 2 de Mayo, and died in a couple of months from the effects, with a typical case of Oroya

fever (1885). His description of the particulars of the disease as it attacked him is one of the most exact and comprehensive studies of any disease extant.

Experimental Tuberculosis.—Richet states that dogs inoculated with pure cultures of the Koch bacillus were exposed to the vapors of turpentine for an hour every week during six months and the development of the infection was definitely arrested, while the control animals all died. —*Presse Méd.*, November 28.

Myositis Ossificans Progressiva.—Stempel has been studying, for three and a half years, a typical case commencing at four years of age. He concludes from his numerous microscopic investigations that the process is not due to the muscles or bones, but proceeds from the connective tissue, originating in some disturbance of the tissues in the embryonal period, producing defective differentiation of the original gelatinous tissue—representing the mesenchyma—which would develop normally into connective tissue on one hand and into bone and joint tissue on the other. If this normal differentiating process is disturbed, the places normally occupied by connective tissue are filled with bone and joint tissue. The coexistence of the other disturbances in development, absence of the terminal phalanges, etc., which generally accompany this affection are also explained by this theory. —*Cbl. f. Chir.*, November 19.

Intestinal Obstructions.—In a previous number of the JOURNAL (p. 966) in an article on "Intestinal Obstructions from Gallstones, with Report of a Case," by J. P. Lord, M.D., Omaha, Neb., an illustration which belonged to a paper appearing later in the JOURNAL was erroneously inserted, in place of the following:

Photographs, actual size, of gallstone, in half section, case of Jere Cooper, operated March 14, 1898, by Dr. Lord.

Photograph, actual size, of gallstone removed from lower ilium of Jere Cooper, by Dr. Lord, March 14, 1898.

Abdominal Fixation of the Uterus.—Henricius reports sixty cases operated on—15 retroflexion or retroversion; 39 prolapsus, or other causes. Three have borne healthy children at term (two operated for prolapsus and one for retroversion). In forty-eight cases, recovery was smooth; in 5 there was a fistula or hernia or both; in one, sepsis from the tube removed, in one case necrosis of the part, the abdominal wall probably too tightly compressed. In one case there was a slight phlebitis of the leg and in another an emphysema in the abdominal wall.

He has collected 122 cases in literature in which abortion followed in 14, premature natural delivery in 3, premature artificial delivery in 1. In 104 cases of delivery at term, there was breech presentation 6 times, shoulder 6, asynclitism of the head, 1; spontaneous delivery in 66 out of the 104; eclampsia in 2.—*Nordiskt. Med. Arkiv.*, xxxi, 5.

Rupture of the Umbilic Cord.—Tissier reported, at a recent meeting of the Paris Medicolegal Society, a case of delivery in a standing posture in which the weight of the child, 2670 grams, broke the cord horizontally across, the divided surfaces as smooth as if they had been cut with scissors. Other cases were related in which the weight of the child had caused the usual oblique rupture, and Charpentier mentioned a case in which a very heavy fetus was accidentally picked up by the cord and suspended a few moments without rupturing it.

Vitality of Severed Human Flaps.—Wentscher asserts that Reverdin's flaps can be kept three weeks without loss of vitality in a 6 to 10 per cent. salt solution, or dry in cotton, and then be successfully transplanted. A brief freezing does not injure them, but they are very sensitive to warmth, long application of disinfectants and much desiccation. The tissue should not be too dry to easily imbibe the protoplasmic stream after transplantation.

Surgical Intervention on the Insane.—Picque of Paris, proposes to increase the discretionary powers of the curator or administrative committee in respect to operations deemed indispensable by the physicians of the asylum that has the insane patient in charge, adding to the present regulations: "The administrator may, in case of conflict with the family, order the application of treatments considered indispensable."—*Presse Méd.*, November 26.

Fundus Oculi Lesions: Correction.—In the report of the paper of Walter Hilliard, M.D., (vide JOURNAL, December 10, p. 1421), in the sentence: "Another feature of importance is the capillary network of the retina, which is the finest and closest in the body," the choroid is meant and not the retina.

Quinin in Malarial Fever.—Dr. Robert Koch having had the temerity to declare that the "black-water fever" of South Africa is really "quinin poisoning," has most effectually injured the reputation of quinin, at least in the minds of the laity in South African territory, and has thereby occasioned a heated discussion in British medical journals and societies. Dr. Koch's opinion is not accepted by the English physicians who are resident in South Africa, and they vehemently protest that it is superficial and fallacious, arguing with liberal references to long experiences, which show that black-water fever patients recover quickly if treated promptly with heroic doses of quinin—that, in the words of Dr. R. U. Moffat of Uganda *British Med. Jour.*, Sept. 24, 1898), "there is only one treatment for malaria: quinin, more quinin, and yet more quinin."—*Am. Therapist*, November.

Tachypodia or "Hot Foot."—The late Dr. Péan of Paris was once called in the capacity of a physician to attend a duel. One of the adversaries was so cowardly that he ran away after the first shot, unhurt. The four seconds, the remaining combatant, and the Doctor stood looking at each other with embarrassment and discomfiture, when Dr. Péan broke the silence by saying gravely, "I know the disease that has suddenly attacked this gentleman," and taking out his pencil and paper, he drew up a report as follows: "At the first shot, Mr. X. was taken with a sudden attack of tachypodia that would not yield to treatment. The seconds, therefore, on consultation with the physician, stopped the duel."—*Medical News*, December 3.

The Pathologic in Goethe.—W. A. Freund contributes an article to the *Munich Med. Woch.* of November 29 that will create a sensation among the admirers of Goethe, as he states

that the fact of the early death of his children and the degeneracy of those that survived, studied in connection with his own illness at one time, which after the most unfavorable prognosis, terminated unexpectedly in recovery in the course of a year, indicate a specific disease cured with specific treatment. The lesions mentioned in his letters, his reference to "Don Sassafras," and his later relapses support this view, which Freund claims explains much of the medical, chemist and philosophic tendency of his writings.

The "Pugwash Plant" of the Indian Doctor.—The man who has worked the country long and successfully as an Indian doctor gives directions for the pursuit of this noble calling. Buy up a job lot of senna and make it into senna tea, with a few other "yarbs." Bottle it and take it out on the road with a wagon. Name it "Yokotami, the Great Blood Purifier of the Pugwash Indians." Men will throng to the wagon to get it, and, going to the edge of the crowd, will take a furtive swig to see how much better they feel. They usually think they do, and after their bowels have moved the next morning they know they do.—*Popular Science News*, November.

Temperature on Determination of Sex.—Molliard stated, at the Paris Académie des Sciences, October 31, that a higher temperature favors the production of females (Düsing), and Schlechter arrives at the same conclusions in regard to horses. Von Siebold has shown that eggs of the nematus ventricosus produced more females as they were kept at a higher temperature, and Molliard confirms this fact in regard to the mercurialis. Knight, on the other hand, has noted that the watermelon raised in a hotbed, has only male flowers.—*Presse Méd.*, November 9.

Bequests.—The late David Leahy of Brooklyn left certain large sums to charitable institutions, of which the St. Mary's General Hospital of Brooklyn receives \$10,000, the St. Mary's Maternity, \$7,500, and the Home for Consumptives of Brooklyn, \$5,000. Several homes for children, and other institutions, together with those named above, are to receive \$100,000, in addition to which a residuary interest in over \$200,000 is left to those charitable institutions and to the Catholic University and Yale College.

Dr. Jacobi Honored.—An anonymous donor has presented \$50,000 for the endowment of a ward for children at the Roosevelt Hospital, New York, the ward to be used for the purposes of the clinical instruction of the students of the College of Physicians and Surgeons, and to be known as the Abram Jacobi ward for children. The trustees of Columbia are to have the right to nominate the persons giving instruction in this ward, and that appointment has been conferred upon Dr. Abram Jacobi, Professor of Children's Diseases. One of the conditions of the gift was that the donor's name should not be made public. Only the students in their final year will be taught in the ward, which will be open to all children, except those having contagious diseases.

For Cuba Libre.—Dr. John Guiteras, Professor of Pathology in the University of Pennsylvania, will resign at the close of the present year to accept the chair of the Practice of Medicine at the University of Havana. Dr. Guiteras has been greatly interested in the liberation of Cuba and wishes to build up the medical courses in the University of Havana.

An Army Medical Examining Board.—The Army Medical Examining Board, which was convened in Washington, D. C., October 10, last, has concluded its present labors by filling all existing vacancies in the corps. The Board consisted of Col. Dallas Bach, assistant surgeon-general; Major Louis A. Le Garde, surgeon, and Captains G. E. Bushnell, G. D. De Shon and E. L. Munson, assistant-surgeons, United States Army. One hundred and seven candidates were invited to appear, but thirty-three failed to avail themselves of the oppor-

tunity; twenty-nine were rejected on account of defective physique and twenty were passed as satisfactory in every respect. Among the successful candidates were Dr. Church, who, as assistant-surgeon of the Rough Riders, distinguished himself in the fight at Las Guasimas, June 25, 1898, and Dr. Ford, the assistant-surgeon of an immune regiment, who came all the way from Manzanillo, Cuba, to have his qualifications tested. The Board has adjourned subject to the call of its president. It has not been dissolved, and may have considerable work before it if Congress passes a bill for the reorganization and increase of the army.

Accident to Hospital Ship.—The *Bay State*, a hospital ship belonging to the U. S. Army, was the scene of an explosion of an ice-making machine at Brooklyn on December 6. The expert engineer in charge of the machine lost his life, and twelve members of the hospital corps of the vessel were injured or temporarily in danger of asphyxiation. The injured men were treated successfully on board of the *Relief*, which chanced to be lying at an adjacent wharf. The *Bay State* was only slightly injured. She was formerly the property of the State of Massachusetts. At the close of the hostilities with Spain, she had been purchased by the Federal authorities and assigned to Chief Surgeon R. M. O'Reilly, whose future post of duty will be at Havana and in Cuban waters, referred to in another item.

Appointment as Contract Surgeon in the U. S. A.—The following requirements are exacted by the Board of Examiners: Evidence of graduation at a regular reputable medical college—diploma to be submitted to the Board. Proof of hospital or other professional experience will be of benefit to the candidate. Candidates must be in good health, of reasonably sound physique, and citizens of the United States. The examination is of a practical nature, embracing hygiene, practice of medicine, pathology and surgery. In addition, a thesis on some professional topic will be prepared by the candidate. The following questions submitted to former candidates are published as a guide to applicants: 1. What chemic and physical qualities of water would lead you to suspect its potability? 2. What are the varieties and pathology of felon? 3. What is Vidal's test? 4. What are the modern methods of treating diphtheria? The pay of acting assistant surgeons is \$150 monthly. The applicant must be free from physical defects which would incapacitate him from the military service. For further information address Major H. S. Kilbourne, Surgeon, U. S. A., Army Building, 39 Whitehall Street, New York City, President of Board of Examiners.

To Profit by British Experience.—Lieut.-Col. R. M. O'Reilly, chief surgeon, Havana, Cuba, has recently been ordered to proceed to Jamaica, with the view of gathering information concerning military sanitary methods in that island, which may be of use to us in our occupation of Cuba. Surgeon-General Sternberg gave him the following special instructions:

In compliance with instructions contained in a letter from the Adjutant-General of the Army, dated Dec. 2, 1898, you are expected to make a careful inquiry with reference to the methods now in use in the island of Jamaica for protecting soldiers of the British Army stationed upon that island, from fatal infectious diseases and from the deleterious effects of climatic influences. You should ascertain, as far as practicable, the results obtained by improved methods which have been adopted as the result of experience, and full details as regards the housing, clothing and feeding of British soldiers in semi-tropical and tropical climates; also the methods found most satisfactory for the disposal of excreta and for the protection of troops from infectious diseases, and especially yellow fever, dysentery, camp diarrhea and the malarial fevers. The measures of prophylaxis adopted, and the results of such measures should be fully investigated. Especial attention should be given to the question of rations and clothing which have been found suitable for the climate of Jamaica; also as to the construction of barracks found by experience to be most suitable and conducive to the health of the soldiers in garrison; also

to everything pertaining to camp equipment and the sanitation of camps as practiced and as required by army regulations and orders. You are expected to make to the Adjutant-General of the Army a full report upon these subjects.

Protection from insects.—A memorandum from the office of the Surgeon-General of the Army, issued as far back as June 13, 1890, does not appear to have attracted the attention of medical journalists. We present it here as being of interest to others than those to whom it was first addressed:

The attention of medical officers of the regular and volunteer armies is invited to the following extracts from a letter addressed to the Surgeon-General by Prof. Stantord E. Chaille of the Medical Department, Tulane University of Louisiana, New Orleans: "Instructions appear to have been issued to our soldiers for the preservation of health in the tropics, and I believe it well worth your consideration whether it would not be well to have disseminated among them information calculated to alleviate greatly their sufferings from mosquitoes, fleas and other insects, sufferings which often deprive soldiers of the sleep and rest which, with food, are the primary requisites for their efficiency. During the Civil War many soldiers blessed me for the following information: Mosquitoes, fleas, bedbugs and, I believe, insects generally detest and will avoid the essential oils and the plants which, with or without bruising, are strongly impregnated with their odor. In New Orleans, oil of lavender is used by many for relief from mosquitoes; a drop or two smeared on a hand or on any naked surface will protect until it dries up, say half an hour. While a Confederate surgeon I was in a town infected with fleas, and secured great relief by using freely in my boots and clothing and about my bed the bruised pennyroyal which grew abundantly within the town. Smearing exposed parts with grease will protect from mosquitoes until the grease disappears. A small piece, say one or two inches square, of fat muddling or bacon to smear on exposed parts is more efficient than essential oils, because the grease does not dry up as soon, and would probably protect during the usual hours of sleep, if used at the beginning and repeated once during the night's rest."

Bills to Reorganize the Army.—Three bills "for the Reorganization of the Army of the United States and for other purposes" have been introduced into Congress. Each has been read twice and referred to the committee on military affairs. The following are the sections of each which relate to the medical department. It seems likely that the provisions in Senate Bill 4900 for so many assistant surgeons-general with the rank of major, captain, etc., are merely the result of clerical errors in copying the bill.

SENATE BILL 4900, introduced by Mr. Hawley. . . .

SEC. 15. That the Medical Department of the Army shall hereafter consist of 1 surgeon-general, with the rank of brigadier-general; 20 assistant surgeons-general, with the rank of colonel; 30 assistant surgeons-general, with the rank of lieutenant-colonel; 175 assistant surgeons-general, with the rank of major, and 120 assistant surgeons-general, with the rank of captain, mounted, and 250 assistant surgeons-general with the rank of lieutenant, mounted. The enlisted force of the medical corps shall consist of 250 hospital stewards, 250 acting hospital stewards and 2000 privates.

SENATE BILL 4938, also introduced by Mr. Hawley. . . .

SEC. 11. That the Medical Department shall consist of 1 surgeon-general, with the rank of brigadier-general; 20 surgeons, with the rank of colonel; 30 surgeons with the rank of lieutenant colonel; 100 surgeons, with the rank of major; 350 assistant surgeons, with the rank of first lieutenant; and a hospital corps consisting of 250 hospital sergeants, who shall have the pay and allowances of hospital stewards; 100 pharmacists, with the compensation of \$40 per month and the allowances of acting hospital stewards; 500 hospital corporals, with the pay and allowances of acting hospital stewards; and 3200 privates. *Provided*, That all vacancies in the grades of colonel, lieutenant-colonel and major created or caused by this section shall, as far as practicable, and subject to the prescribed examination, be filled by promotion, according to seniority, as now provided by law. *Provided also*, That assistant surgeons shall have the rank of first lieutenant for the first five years' service, and that of captain after five years' service, subject to the examination now provided by law. *And provided further*, That the period during which any assistant-surgeon shall have served as a medical officer of the volunteer army during the war with Spain shall be counted as

a portion of the five years' service required to entitle him to the rank of captain.

Acting assistant-surgeons may be appointed by the surgeon-general, with the sanction of the Secretary of War, and under such regulations as may be prescribed by him, for temporary service, whenever imperatively necessary, at a compensation not to exceed \$150 per month. *Provided*, That no one shall be so appointed until he shall have passed a satisfactory professional examination.

HOUSE BILL 11022, introduced by Mr. Hull. . . .

SEC. 11. That the Medical Department shall consist of 1 surgeon-general, with the rank of brigadier-general; 10 surgeons, with the rank of colonel; 20 surgeons, with the rank of lieutenant-colonel; 110 surgeons, with the rank of major; 360 assistant surgeons with the rank of captain or first lieutenant; and a hospital corps consisting of 250 hospital sergeants, who shall have the pay and allowances of hospital stewards; 100 pharmacists, with a compensation of \$40 per month and the allowances of acting hospital stewards; 400 hospital corporals, with the pay and allowances of acting hospital stewards; and 3000 privates. *Provided*, That all vacancies in the grades of colonel, lieutenant-colonel and major, created or caused by this section, shall, as far as practicable, and subject to the prescribed examination, be filled by promotion, according to seniority, as now provided by law. *Provided also*, That assistant-surgeons shall have the rank of first lieutenant for the first five years' service, and that of captain after five years' service, subject to the examination now required by law. *And provided further*, That the period during which any assistant-surgeon shall have served as a medical officer of the volunteer army during the war with Spain shall be counted as a portion of the five years' service required to entitle him to the rank of captain. *Provided further*, That all vacancies in grade of assistant-surgeons shall be filled by competitive examinations, as now provided by law.

Acting assistant surgeons may be appointed by the Surgeon-General, with the sanction of the Secretary of War, and under such regulations as may be prescribed by him, for temporary service whenever imperatively necessary, at a compensation not to exceed \$150 per month. *Provided*, That no one shall be so appointed until he shall have passed a satisfactory professional examination.

Medical Registration in Connecticut.—The regular examining committee of the Connecticut Medical Society has held eight special examinations during the year 1898, the last one on November 8. Seventy-five applicants were examined, five of whom were for midwifery only and seventy for general practice. Of the seventy general practitioners, thirty-nine were found qualified and twenty-one not qualified, while six were conditioned. Of the latter, three were afterward examined and found qualified. The results of the last examination have not been reported to the State Board. One of the rejected midwives was also re-examined and passed. This committee and the two other official examining committees have held a conference and decided to apply to the State Board of Health to appoint the time and place for examinations only once in four months, i. e., in March, July and November; that all examinations shall be written in English, and that at least 75 per cent. of answers must be correct to enable a candidate to pass, but that "conditions" may be allowed, if there are not more than two branches under a marking of seventy-five, and the markings not less than fifty, with re-examination at the expiration of four months.—*Medical News*, December 3.

Hospitals.

By the will of Josiah B. Thomas of Peabody, Mass., \$50,000 is left for the founding of a hospital in Peabody.—The new St. Luke's Hospital, Bayonne, N. J., was formally opened for patients December 3.—The Presbyterian Hospital, Chicago, has received \$50,000 as a Christmas gift, from Mrs. Averell of Chicago, to endow a free ward of ten beds for men, to be known as the Albert J. Averell Memorial Ward.

Cincinnati.

HEALTH REPORT.—The Health Department reports an average of nine cases of chickenpox per day. The cases of smallpox at the branch are all doing well.

PERSONAL.—Dr. Lawrence Shields, who has held the posi-

tion of resident physician at the Cincinnati Hospital for the last two years, has accepted the post of associate to Dr. Parsons of Mexico City.

Washington.

REPORT OF HEALTH OFFICER.—The report of Health Officer Woodward for the week ended December 10 shows the total number of deaths to have been 1119, 73 white and 46 colored. The principal causes of death were apoplexy, bronchitis, consumption, diphtheria, nervous, circulatory, genito-urinary, pneumonia, malignant growths, and typhoid fever. The total number of births was 127, 77 white and 50 colored. At the close of the week there were 122 cases of diphtheria and 129 cases of scarlet fever under treatment.

EMERGENCY HOSPITAL NURSES' HOME.—The new home for the nurses of Emergency Hospital, the gift of Mrs. Phebe Hurst, was formally opened, December 7. The hospital superintendent, Miss Simonton, received several hundred callers, all interested in hospital work. The home is located opposite the hospital, has the ambulance stable adjacent, and is connected with the hospital by electric signal. A large number of rooms in the hospital, formerly occupied by the nurses, will now be vacated, and the space used for the accommodation of patients.

COLUMBIAN GRADUATES IN THE ARMY.—At the recent competitive examination for Army surgeonships, none of the graduates of the Columbian Medical College failed. The list included Drs. James R. Church, surgeon of the Rough Riders, J. H. Ford and Dr. Wolf. The best examination was passed by J. H. Ford, member of the class of '97.

HOSPITAL FOR FOUNDLINGS.—At the 12th annual meeting of the Board of Directors of the Washington Hospital for Foundlings, recently held, Dr. Z. T. Sowers was elected president. The following staff was also elected: Drs. Z. T. Sowers, chief of staff, D. K. Shute, ophthalmologist; C. W. Richardson, laryngologist and M. F. Cuthbert, R. W. Baker, Samuel S. Adams and J. R. Wellington.

London.

HARVEIAN LECTURE.—The first Harveian Lecture was delivered this week by Dr. Wm. Ewart at St. George's Hospital and College. The series of three is to cover "Disease and its Treatment and the Profession of Medicine in 1899." The first lecture dealt with the present aspects of disease, and after a rapid sketch of the disappearance of many diseases and the diminution of others, the immense advances in our means of recognizing and treating them, etc., Dr. Ewart settled down to a broad and philosophic consideration of the interesting questions: "Can Disease Entirely Disappear?" "Will Such Approach to Disappearance as may be Expected Seriously Limit Our Usefulness and Field as a Profession?" The first of these questions he quickly answered in the negative, pointing out, as Clifford Allbutt pithily remarked some years ago, "Die we must, somehow," and every life saved from infections, and diseases of malnutrition simply meant an adult to die later on of, say arterio-sclerosis or of cancer. It was theoretically possible for death by old age to be a purely natural, even physiologic, process, but practically it was extremely rare that all men "went to pieces all at once," like our beloved Holmes' immortal "One-hoss Shay." Some "weaker place can't stand the strain," gives way, and death occurs by what we term "disease." As to the effect of the diminution of disease upon the profession, he held that while it had perhaps temporarily diminished the amount of employment for us in certain directions, yet upon the whole it had distinctly widened our field so far. Our standards of health were much higher, there was a keen desire to avoid risk of disease, a determination to have even discomfort alleviated, on the part of the community, which was bringing thousands of patients whom formerly we would never have seen. As he summed it up, "Disease had diminished, treatment increased." He cited American experience as bearing out this position and expressed the hope that the day would come when England would attain as high a standard of thoughtfulness and foresight in the removal of all possible conditions of disease and calling skilled attention to the very earliest symptoms "as obtain in Transatlantic Britain." He also referred to the wide field opening up to the profession in the supervision of education, and, in fact, took a strikingly similar position to that assumed editorially by the *JOURNAL* a few weeks ago.

MOLLUSCUM CONTAGIOSUM, CANCER, ETC.—At Mr. Jonathan Hutchinson's clinical demonstration last week a case of molluscum contagiosum was presented with the history that a generalized outbreak of the eruption had developed some three weeks after the patient had taken a Turkish bath. Upon

which the lecturer remarked that, in his experience, nearly every case of widespread molluscum contagiosum in an adult, had developed very shortly after taking a Turkish bath, and that he believed the disease to be often due to the use of infected "public" towels, vigorously applied to a softened and heated skin. It would be interesting to notice whether such a connection could be traced upon the other side of the Atlantic. It was also stated, in commenting upon a case of cancer, that in the lecturer's opinion the children of parents who married late in life were more liable to cancer than those of young parents. This was one of the factors in the increasing prevalence of cancer, as marriages occur usually at a much later age than formerly. The other and weightier factor was that cancer being a disease of adult or late middle life, and a larger proportion of children surviving to attain this age, the proportion of those in the community liable to its attack was markedly increasing. Mr. Hutchinson said that he had been much interested of late in the question of disease liability of the children of old parents, and asked for information from his hearers as to the truth of the statement that grafts taken from an old apple tree and inserted in a young root-stock would live only as long as the parent tree. Gardeners had assured him that it was an accepted rule among them that when the old tree died the grafts were sure to follow very shortly. If this be true it would appear that every part, even of a composite community like a tree, had a more or less definite and limited life expectation determined by that of the whole. Does this apply to our own tissues, including our generative cells, and has a race a life-period like an individual?

LORD LISTER, in his presidential address at the late annual meeting of the Royal Society, dwelt chiefly upon the late triumphs of preventive medicine and announced that Dr. Turner had discovered a method of protection against the terrible African rinderpest, by inoculation of serums along the line suggested by Koch and that 700,000 cattle had already been saved by it and there was hope of entirely eradicating it.

Philadelphia.

DR. AND MRS. S. WEIR MITCHELL have sailed for Egypt, where they will spend several months.

DR. WILLIAM PEPPER, JR., who has recently recovered from a severe attack of typhoid fever, sailed last Saturday for the south of Europe and will cruise in the Mediterranean for several weeks.

QUARANTINE AGAINST RABID DOGS.—Dr. J. C. McNeal, of the Department of Public Safety of this State, has reported to State Veterinarian Leonard Pearson of this city that a large number of rabid dogs exist in the Sewickley Valley. At a recent meeting of the Live Stock Sanitary Board, called by Governor Hastings, at the request of Dr. Pearson, action was taken and all dogs in the Sewickley Valley were quarantined.

GIFT CONTESTED.—The will of Sarah Donnell, who recently bequeathed the bulk of an estate valued at \$10,000 to various charitable institutions, including the Episcopal Hospital, is being contested by her sister, who recently filed a caveat with the Register of Wills. The ground on which the contest will be brought has not become public.

VISIT TO SOUTHERN ARMY CAMPS.—Dr. M. S. French, secretary of the National Relief Commission, left last week on a visit to the different army camps throughout the South. On his return trip Dr. French will visit the different hospitals along the Atlantic seaboard, including Savannah and Fort Monroe.

LA GRIFFE PREVAILING.—Early in the week a few scattered cases of gripe made their way to the hospitals. Later the school children became affected, and now it seems scattered abroad throughout the city.

DIAGNOSIS SUSTAINED.—It will be remembered that last week Dr. W. B. Atkinson of the State Board of Health was sent to investigate the suspicious cases of skin disease epidemic throughout the town of Bradford, Pa., and the surrounding country. Dr. Atkinson is reported as finding a number of cases with symptoms so manifest that he at once reported them as smallpox. This diagnosis seemed to startle a good many of the practitioners in Bradford, and they had no hesitancy in stating that the diagnosis was incorrect. A public meeting was called and rousing resolutions adopted setting forth the

opinion that smallpox was not epidemic in the locality. However, smallpox has continued to spread throughout the city, and on December 11 twenty cases were reported. Dr. Benjamin Lee, secretary of the State Board of Health, also visited the place and concurred in the diagnosis as expressed by Dr. Atkinson.

MEDICO-CHIRURGICAL COLLEGE.—Plans are now under consideration for the erection of a laboratory for this medical college which, when completed, will cost several hundred thousand dollars. A plat of ground adjoining the property and extending along Cherry and Seventeenth Streets has been purchased. At the meeting of the trustees, to be held in January, it is rumored that the matter will be formally discussed, as up to the present time nothing has been decided as to the style of the proposed building.

LEGISLATION FOR PURE FOOD.—Delegates from this city have been appointed to the Pure Food and Drug Congress which meets in Washington on January 18. The special duty of this Committee is to urge upon Congress the importance of the Brosius bill now before that body, which provides against adulteration of food and drugs. Secretary Smedley is quoted as saying that the various exhibitions at the food show recently held here prove the ingenuity of the adulterants in counterfeiting both the flavor and appearance of food products to an alarming degree. For instance, strawberry jelly is made of glucose, gelatin, anilin dye and artificial flour; cayenne pepper is mostly gypsum; black pepper is largely gypsum and ground cocoanut shells; mustard is principally wheat flour, cayenne pepper colored with a poisonous drug known as Martin's yellow.

A HEALER WITHOUT DRUGS.—Mr. Carol Morton of New York recently gave an address in this city on "Christian Science," and is reported as saying that Christian science is in thorough harmony with the spiritual significance of the Bible. In fact, the Bible is the text book mostly used. Christian scientists accept Christianity according to Christ instead of Christianity according to the dogmas of men. God, the Supreme Being, is certainly synonymous with nature. Health of body, like holiness or wholeness of character, is the normal condition of the image of God, man and woman. Jesus healed the sick and reformed the sinner by the same method. He did not use drugs or material methods. He operated through mental or psychic laws. Christian science has nothing to do with faith cure, spiritualism, theosophy nor hypnotism, but it can not agree that the practice of medicine is a science.

STUDENTS AND THE MUNICIPAL HOSPITAL.—At the meeting of the city council last week, Dr. Walk, a member of that body, who offered the resolution providing that students of the different medical colleges be permitted to visit, for instruction, the patients suffering from diphtheria and smallpox at the Municipal Hospital, has not pressed the resolution as if he thought it would prevail. In fact, so much opposition has been created and ill-feeling engendered on account of this resolution, that instead of being its advocate at the last meeting of the council, Dr. Walk was absent, and it was given out that he will not press the measure any further.

FOR NEW LABORATORIES.—The committee appointed for the purpose of soliciting subscriptions for the new laboratories at the University, to cost \$300,000, report that they have received much encouragement in the work. The plan is to enlist the 6000 medical alumni and thus form centers of local associations under one general alumni association, and thus unite all the graduates in medicine. This is the first general call for contributions from the medical alumni for improvements at the University, and much is hoped for this plan. Provost Harrison has stated that these new physiologic, chemic and pathologic laboratories would be the next building erected during the coming year, and that he would guarantee that one half the expense of the building would be \$150,000.

PHYSICIAN RESIGNS.—Dr. John M. Foyst, who has been for the past few years physician to Girard College, has resigned his position and will engage in private practice. The position pays a salary of \$900 a year, and places a suite of rooms, meals and a servant at the disposal of the occupant. No successor has yet been chosen.

APPEAL TO BOARD OF HEALTH.—Residents of a certain district of Germantown, this city, have made a formal protest against the condition of a neighborhood of Pulaski Avenue, Morris Street and Chelton Avenue, which is being circulated among the residents of that locality to be subsequently turned over to the Board of Health. It is stated that during the past few months considerable sickness has occurred there and that many cases of diphtheria have existed, from which four deaths

have occurred. The locality is believed to be in an unsanitary condition, from the fact that large pools of water are said to form in the gutters, and that at the present time microbes abound.

MICROSCOPE OF FIFTY YEARS AGO.—Dr. J. Cheston Morris recently gave a lecture on "The Development of the Microscope," before the microscopic section of the Academy of National Sciences. He said that in 1850 there were upright microscopes of German and French make, and that one of the greatest improvements was the Ross stand, which enabled a person to examine an object at any angle. Achromatic lenses were made afterward, and many of the latest improvements were due to American opticians and mechanics.

MORTALITY STATISTICS.—For the week ending at noon, December 17, there had been 481 deaths, an increase of 45 over last week, and 30 over the corresponding period of last year. In children under the age of five years, 118 occurred.

FREE HOSPITALS FOR POOR CONSUMPTIVES.—The proceeds of the Philopatrian Ball will go toward the expense of these patients. Instead of erecting a new building for the treatment of these cases, certain wards will be set apart in those hospitals which will care for the tuberculous, and to them the proceeds will be distributed. The hospitals which have taken the greatest interest in this work are the St. Agnes and St. Mary's. The amount of money paid each week for the support of these patients is \$5.00.

THE PUBLIC SERVICE.

Movements of Army Medical Officers.—Special Assignments: Col. Charles R. Greenleaf, assistant surgeon-general, U. S. A., to Savannah, Ga., and to such other places as may be necessary for the purpose of inspecting the medical department at that and other stations. Col. Wm. H. Forwood, assistant surgeon-general U. S. A., from the U. S. Soldiers' Home, Washington, D. C., to duty as chief surgeon department of California, San Francisco, Cal., relieving Lieut.-Col. Johnson V. D. Middleton, deputy surgeon-general U. S. A., on his retirement from active service. Major Henry S. Kilbourne, surgeon U. S. A., to report to the quartermaster-general as medical inspector of transportation. Acting Assistant-Surgeon Aristides Agramonte to Havana, Cuba, on business connected with the study of the cause and prevention of yellow fever, under special instructions from the surgeon-general of the army.

Medical Supplies: Major John B. Hall, surgeon U. S. A., from mustering-out duty in Pennsylvania to San Francisco, Cal., to assume charge of the medical supply depot at that place. Major James E. Pilcher, brigade surgeon, Vols., from the Seventh Army Corps to duty as supply officer at Savannah, Ga.

To Santiago: Major Randall R. Hunter, brigade surgeon, Vols., from leave of absence to report to the commanding general; and Acting-Assistant Surgeons Frederick Hadra, Frederick W. Fabricius, from the Josiah Simpson General Hospital, Va., and John C. Greenewalt from Fort Thomas, Ky., all via New York City.

To Pinar del Rio: Acting Assistant-Surgeons George B. Lawson and F. Medina Ferrer to report to Brig.-Gen. George W. Davis for duty with troops going to that province.

To Porto Rico: Major John Van R. Hoff, surgeon, U. S. A., assigned as chief surgeon of the Department. Acting Assistant-Surgeon E. A. Southall, via New York City to Ponce for duty with the Nineteenth U. S. Infantry.

To the First Army Corps: To report to the commanding general at Macon, Ga., Capt. Charles E. B. Flagg, assistant-surgeon, U. S. A., from the General Hospital at Fort McPherson, Ga.

To the Second Army Corps: Major Edgar A. Mearns, brigade surgeon, Vols., from the First Army Corps to Athens, Ga., for duty with the Third Division.

To the Fourth Army Corps: Major Henry D. Thomason, brigade surgeon, Vols., and the following acting assistant-surgeons to report to the commanding general at Huntsville, Ala.: R. E. Caldwell from Richmond, Va.; Charles Farmer from Lexington, Ky.; R. L. Taylor from the Josiah Simpson General Hospital, Va.; Edwin P. Wolfe from Washington, D. C., and J. Stebbins King from New York City.

To the Seventh Army Corps: Major Ira C. Brown, brigade surgeon, Vols., to report to the commanding general; Major William S. Bryant, brigade surgeon, Vols., to Brig.-Gen. Lloyd Wheaton as chief surgeon, First Brigade, First Division, and Major George B. Bunn, brigade surgeon, Vols., to Brig.-Gen. H. C. Hasbrouck as chief surgeon, Second Brigade, Second Division.

To mustering-out duty: Major Ezra Woodruff, surgeon, U. S. A., from Fort Trumbull, Conn., to New York City for N. Y. Vols.; Major W. C. Borden, brigade surgeon, Vols., at Washington, D. C., for the Fifth Company U. S. Vol. Signal Corps; Major Richard W. Johnson, brigade surgeon, Vols., at Chicago, Ill., for the Seventh Company U. S. Signal Corps, and Capt. Henry R. Stiles, assistant-surgeon, U. S. A., at Portland, Me., for the Eighth Company, U. S. Vol. Signal Corps.

To duty at hospitals, etc.: General Hospitals: Major Benjamin F. Pope, surgeon, U. S. A., to Savannah, Ga., for duty pertaining to the supervision of the construction of the general hospital at that place, and as surgeon in command of the hospital when completed. To the Josiah Simpson Hospital, Va.: Major Edwin F. Gardner, surgeon, U. S. A., from duty with the Third Division, Second Army Corps. To the Hospital Ship *Relief*: Lieut. Weston P. Chamberlain, from the General Hospital, Fort Monroe, Va. To the Hospital Ship *Bay State*: Acting Assistant-Surgeons Charles E. Marrow from the *Relief* and Randolph M. Myers from sick leave in Washington, D. C. To the Hospital Transport *Mobile*: Acting Assistant-Surgeon Charles B. Mittelstaedt to Savannah, Ga. To the U. S. Hospital R. R. Train: Acting Assistant-Surgeon C. L. G. Anderson.

To duty at Military Posts: Major Louis A. La Garde, surgeon U. S. A., from Fort Robinson, Neb., to the U. S. Soldiers' Home, Washington, D. C., as attending surgeon. To the Washington Barracks, D. C.: Acting Assistant-Surgeons C. B. Millhoff, from Johnstown, Pa.; Benjamin J. Edger, from the General Hospital, Fort Myer, Va., and Isaac W. Brewer, from sick leave in Washington, D. C. To Columbus Barricks, Ohio: Major William J. Wakeman, brigade surgeon, Vols., from sick leave, and Acting Assistant-Surgeons Harold W. Cowper, from Fort Myer, Va., and Louis T. Hess, from Washington, D. C. To Fort Adams, R. I.: Capt. George J. Newgarden,

assistant-surgeon, U. S. A., from duty at Savannah, Ga. To Fort Leavenworth, Kas.: Lieut. Basil H. Dutcher, assistant-surgeon, U. S. A., from Fort Grant, Ariz., and Acting Assistant-Surgeon Francis M. McCallum. To Fort Grant, Ariz.: Acting Assistant-Surgeon John E. Bacon, from Fort Hancock, N. J. To Fort Crook, Neb.: Acting Assistant-Surgeon John R. Hicks, from the General Hospital, Fort Monroe, Va.

Leaves of absence granted or extended: Majors Charles Richard and William R. Hall, surgeon, U. S. A.; Lieut. Clyde S. Ford, assistant-surgeon Fourth U. S. Vol. Infantry, and Acting Assistant-Surgeon E. W. Pinkham.

Sick leaves granted or extended: Major Wallace Neff, brigade surgeon, Vols.; Capt. John D. Howe, Assistant-Surgeon, Sixth Ohio Infantry; Lieut. Maurice C. Ashley, assistant-surgeon, First New York Infantry, and Acting Assistant-Surgeons Charles S. Stern, E. Van Hood and Isaac W. Brewer.

Resigned: Major Burton S. Booth, surgeon Two Hundred and Third New York Infantry; Major Salem Heilman, surgeon, One Hundred and Fifty-Seventh Pennsylvania Infantry; Lieut. F. L. Albritton, assistant-surgeon Sixth Ohio Infantry, and Lieut. Paul M. McCreay, assistant-surgeon Fourth New Jersey Infantry.

Honorably discharged: Major William H. Arthur, chief surgeon Vols. (Major and Surgeon U. S. A.) his volunteer commission only; Major Wallace Neff, brigade surgeon, Vols.

Contracts annulled: The following acting assistant-surgeons: From the General Hospital, Fort McPherson, Ga., James H. McCall, of Hunt- Tenn., Edwin M. Patterson of Washington, D. C., and James C. Ross of Salt Lake City, Utah. From Washington, D. C., Frank Garnett Young of Clarksburg, W. Va. From Fort Meyer, Va., Edwin C. Barstow of Washington, D. C. From the Josiah Simpson Hospital, Va., Wallace S. Chapman of Denver, Colo., and from the General Hospital at Ponce, P. R., John L. Goltra of Buffalo, N. Y.

CHANGE OF ADDRESS.

Allen, B. G., from Robbins, Tenn. to Somerset, Ky.
Brooks, S. D., from Port Townsend, Wash. to Nat'l Quarantine Station, Angel Island, Cal.

Brewster, B. H., from Hooper to Petrolia, Pa.

Campbell, J. G., from 5107 Lexington ave. to 6857 Wentworth ave., Chicago, Ill.

Chapple, C. L., from Asbury to Barrabas Hospital, Minneapolis, Minn. de Beque; W. A. E., from De Beque to Youngerman bldg, Des Moines, Iowa.

Fenelon, M. P., from Rippon, Wis. to Cartville, La.

Graham, C. A., from 16th and Curtis street to box 764, Chicago.

Joslin, H., from Stedman bldg to 921 Logan ave., Denver, Colo.

Kreass, S. S., from 1316 to 1510 Walnut street, Philadelphia, Pa.

Loper, J. B., from 415 8th to 1213 25th, Des Moines, Iowa.

Parker, W. T., from Asylum Station to Westboro, Mass.

Patterson, R. N., from Oakland to 1606 California street, San Francisco, Cal.

Shortridge, W. R., from Elgin, Ill. to La Plata, Mo.

Sweeney, A., from 366 Wabasha street to Lowry Arcade, St. Paul, Minn.

Van Fradenburg, G. A., from Alcott to Manassa, Colo.

Wilson, H., from Lima, Ohio to North Loup, Neb.

Whalen, C. J., from 237 North Clark to 235 Dearborn ave., Chicago, Ill.

HYGIENE AND DIETETICS IN DIABETES MELLITUS

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association held at Denver, Colo., June 7-10, 1898.

BY FRANCIS E. CARROLL, M.D., A.B.

BOSTON, MASS.

If perfect culture of mind and body was to be had, a perfect knowledge of the laws of life, an intellect and body trained, the moral faculties of man in balanced order, the human race would not perish under a grievous yoke of disease; the youth of man would be protected and become more perfect; decay of life would be blended with happiness of perfect knowledge; life would become more vigorous, disease more remote. Life is an entity, a constant growth, a resultant waste, a potential energy, an eventual expenditure. No agent has been found to arrest the waste or crystallize the tissues of growth and vigor from decay. To do so would be death itself, for life is an incessant change, its vital energy dependent upon the laws of nature, a neglect of which inevitably produces lamentable results. To prolong the period of vital energy, the improvement of the nutrition of the tissues is necessary, either by hygiene or by preparing the proper food for the purposes of nutrition, or removing or preventing those chemic changes in the tissues, called decay. The benefits derived from these principles have extended the duration of life, and it is from this irresistible inference—the instruction derived from experience—that the hygienic and dietetic treatment adapted to diabetes mellitus can abridge or prolong human life. It would be wise had man a mystic elixir capable of preserving life, where there had been injurious habits and old damages, of rendering a stream pellucid which is turbid at its source, but our nature, having no *Deus ex machina*, must look to the proper supervision of that upon which health and life are dependent.

One great means in the efficacy of hygienic treatment of diabetes mellitus is *air*. The air influences, by variations in the amount or condition of its normal constituents, by difference in physical qualities, or by the presence of impurities. The patient should be surrounded by most favorable hygienic influences, because of the mischievous consequences of the disease proceeding slowly or rapidly according to the constitution, age of patient and circumstances in life. No one who has paid any attention to the condition of health in disease can doubt that impurity of air marvelously affects the individual in the convalescent state. The respiration, and cutaneous emanations of man, the impurities from combustion of light and heat, the effluvia of uncleanness of rooms and persons, demand that the sleeping-room should be well

ventilated, removed from any impure flow of air, and that the house should be wholesome and well drained. The patient should pass much of his time in the open air, the action of the sun's rays vitalizing the atmosphere and imparting vigor and energy to the system. During the cold of the winter a glass house with southern exposure is a great comfort. For cleanliness and to preserve a healthy state of the skin, bathe regularly in water not too cold, not allowing the body to be long submerged. After a warm alkaline bath in winter, or a tepid bath in summer, either on retiring at night or arising in the morning a brisk friction or massage, using coca oil, facilitates the removal of effete epithelium, and is conducive to stimulating a healthful action to an otherwise dry and harsh skin. A foot-bath of hot water, with the addition of a tablespoonful of mustard, is very useful where there is fulness of blood-vessels in the head, continued sleeplessness or obstinately cold extremities. Warm flannel next to the skin, and residence in a warm equable climate is an aid to health.

For individual life to continue to exist, the healthfulness of its envelope—the body in which it dwells—must be preserved. So the ingesta, which goes directly or indirectly to the growth, repair or the production of energy in any form, must be administered to insure the proper continuity of the body, its textures, its organs, its processes and actions. Alimentation and beverages are necessary to the existence of all organized beings, but the requisite quality and quantity depend very much upon the circumstances connected with each individual case. It is quite obvious, that to accomplish the best results in the processes of healthy nutrition, the application of dietetic principles is a most prominent feature, and in the widest acceptance of the term it is of prime importance—the corner-stone in the treatment of diabetes. A necessary reform of diet should be had in diabetes. A strict disciplinarian subjects his patient, without reason, to a stringent diet; another, more captious, permits every conceivable latitude. A conscientious, docile patient obeys the strict rule, gets disgusted with mutton or beef, and alimentation in general, consequently is nauseated by a meat diet and abandons it. A capricious, covert one, disregards all necessity, and deceives the animal economy.

The efficiency of diet depends upon the proper elimination of all ingesta containing grape-sugar, cane-sugar, beet-root sugar and starch. The glycogenic function of the liver and its hepatic action on carbohydrates renders food of such assimilative nature injurious, aggravates the glycosuria, and the excretion of sugar gradually increases. A certain, exact determination of ingesta and its effects in reference to carbohydrate metabolism should be outlined and noted. The normal, assimilative action of the liver should be enabled to be approximately defined, and its carbohydrate metabolism estimated, by exclud-

ng the patient from a generous diet and directing a strict diet from ten days to a fortnight. After having followed this cautious procedure, a standard is obtained whereby the effects of a stringent diet can be readily determined.

In many cases, a gradual substitution of articles of a mixed diet, in definite quantities, may be cultivated with advantage, and should sugar reappear, the diet can be duly regulated. In severe cases, carbohydrates should be permitted and results noted. In a large number of diabetics, a pure skim-milk regimen results in a total disappearance of sugar, whereas others can take milk and potatoes, in small quantities, with success, and with slight increase in amount of sugar. Individual idiosyncrasies must be watched and suspected, as some patients tolerate starch in one form better than in another, as bread rather than potato. Many diabetic foods possess an injurious amount of starch, and others are useless and absolutely indigestible, so that the *summum bonum* of diet must be insisted upon with such additions as are judicious. An exclusive animal diet may reduce, or cause the sugar to disappear, but it can not always be tolerated, for appetite will grow "stale," and the necessity of a mixed diet becomes a serious study. In this disease, the nervous system is correspondingly implicated and a rigid devotion to animal ingesta increases the tension, for there is a physical degeneration peculiar to this affection, and a mixed diet is the wisest course to pursue. When thoughtfully regulated, such a regimen is more likely to keep the disease stationary by upholding vitality than by being confined to one diet, while the stomach and system become debilitated with results of innutrition, and sooner or later succumb to the fell destroyer. Milk, when assimilable, is a boon to the invalid. When digestion is apt to be deranged, peptonized milk may be substituted, but the monotony of a milk diet becomes unbearable. Cream, as long as it agrees, may be allowed, and cod-liver oil is a nutriment, particularly where fatty articles are easily retained.

To many of the laity there are certain fixed principles by which this disease must be attacked; and one is that complete abstinence from amylaceous food or any liquid or substance convertible into sugar is necessary. Logically true these premises may be, yet a suitable diet, eliminating all saccharine and amylaceous, sugar-producing substances, strictly speaking, is impossible. There is skim-milk treatment, best used in the incipient stage, causing the sugar to disappear, and an abatement of symptoms as long as the diet is rigidly followed; in others, where disease is persistently established, it is not of any use, despite all treatment. Even in later life, when diabetes is most amenable, fat meats, eggs, soups and fish may be taken daily, to vary the diet as much as possible, taking the hearty meals in the earlier part of the day. The most important article of diet—bread—deprivation of which is illy borne by the patient, is a source of careful thought to the physician—the substitutes of bread are so various, imperfect and injurious. Gluten flour, however prepared, possesses starch. Where extreme discipline is required, the carefully prepared bran, thoroughly washed and free from starch, or bran prepared by the cold-air blast process, may be used. Pavy's almond food, Seegeus' almond food, Camplin's method of making biscuit of bran flour, Kuelitz's biscuits of inulin from Iceland moss, are substitutes for bread. When exclusive diet is not determined the ordinary bran may be used.

In the nature of beverages, milk, combined with lime water, soda water, or buttermilk, is good, or a refreshing draught is Apollinaris, Vichy or carbonated waters. There is no water that so alleviates the distressing thirst of the diabetic as Waukesha Bethesda water. Certain mineral waters have long enjoyed an overestimated reputation in diabetes, as the Vichy and the Carlsbad, due to their aperient action on the liver and bowels. Mineral waters in America are legion, and each has its exponent with proofs accordingly.

Use of alcohol in diabetes demands careful attention. If used, non-saccharine wines are prescribed—hock, Bordeaux, and German or French wines, even dry sherries and madeira—but under suitable restriction. Bordeaux claret is preferable to whiskey, and no malt liquors or strong alcoholic drinks should be allowed. Alcohol should be prohibited when it acts detrimentally to the nervous system and when albuminuria is present. With all due regard to alcohol, the animal economy is best without it. The great object, in dietetic treatment of diabetes, is to manage digestion, and check or diminish the formation of sugar.

The writer, having confined the paper to hygiene and dietetics, has purposely avoided medicinal treatment, and trusts, however inefficient the line of thought has been, the reader will pardon the meager discussion of a subject most important to the laity. He will now offer a bill of fare, trying to be liberal enough to satisfy the palate of the diabetic, and subject to the blue pencil of the physician in his special case:

PERMITTED.

Meats.—Flesh meats of every variety: beefsteak, beefsteak with fried onions, mutton or lamb chops, roast beef, corned beef, kidneys, broiled or stewed, smoked beef, calfs' head, sweetbreads, lamb fries, veal, tripe, ham, bacon, tongue, sausage, pigs' feet. *Poultry and Game.*—Broiled chicken, chicken salad, game cooked in every way. *Fish, fresh and salted.*—Fish in oil, sardines, spawn, lobsters, oysters, clams, crabs and shrimps. *Eggs.*—In every way, scrambled, boiled, omelets of all kinds, wherein flour, sugar and prohibited vegetables are not used. Cream, butter, cheese, sour milk. *Soups.*—Animal broths, beef, veal, chicken, ox-tail, turtle, oyster broth, clam broth, terrapin, avoiding vegetables inadmissible, and flour and starchy substances, as rice and vermicelli. *Green Vegetables.*—Summer cabbage, turnip tops, spinach, watercress, mustard and cress, green string beans, green ends of asparagus tops, green parts of lettuce, celery tops, sorrel, mushrooms, dandelions, sauerkraut, cucumbers, olives, pickles. Use moderately cauliflower, brussel sprouts, young onions, broccoli. *Fruits.*—Gooseberries, red currants, plums, cranberries, strawberries, cherries—acidity neutralized with soda bicarbonate. *Bread.*—In known amount, made of gluten, bran, almond flour or inulin. *Custard.*—Made without sugar. *Nuts.*—Almonds, walnuts, brazils, hazels, filberts, pecans, butternuts, cocoanuts. Salt and pepper may be used. *Drinks.*—Tea, coffee, cocoa from nibs, mineral waters, soda waters, dry sherry, claret, acid wines, dry sauteur, rhine, moselle, burgundy, chablis, hock, brandy, gin. No malt liquors. Burton, when long bottled; light beer in moderation, also bordeaux. Glycerin may be used instead of sugar in tea or coffee when imperative, but it is wise to eliminate it as a substitute for sugar altogether.

PROHIBITED.

Sweet dishes—sugar in any form. *Bread.*—Wheaten bread, ordinary biscuits of all kinds; cake, desserts made with flour or sugar; puddings and pastry of all kinds; honey, rice, corn, flour, sago, tapioca, arrow-root, macaroni, vermicelli. *Farinaceous or Saccharine Vegetables.*—Potatoes, artichokes, turnips, carrots, parsnips, peas, beans, beets, spanish onions, asparagus, tomatoes, stalks and white parts of cabbage, lettuce, cauliflower, celery, broccoli, radishes. Liver of all animals; nuts, chestnuts; fruits of all kinds, fresh or preserved; jams, syrups, sugars; diabetic foods, sweet pickles. *Drinks.*—Chocolate, sweet wines, sparkling wines, port wine, liquors, sweet ales, mild and old; porter and stout, cider. Milk does not need to be absolutely banished, but if used, use sparingly.

IMPORTANCE OF PHYSIOLOGY AND DIETETICS TO THE SURGEON.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY CHAS. G. PLUMMER, B.S., M.D.

SALT LAKE CITY, UTAH.

The dimensions of this subject are such that it is impossible to encompass it by the confines of a single article, in a limited time.

The relationship existing between physiology and surgery, in every phase of our profession, is so intimate that, to think or work in the latter without a thoughtful consideration of the former, can never lead to successful results. When we look at what is done by our masters in surgery, we are convinced that they only attained such perfection in their handling of surgical subjects by close application of the very principles of the science. To become merely a flash operator or a mechanic demonstrator of what the human hand, aided by a well-trained eye, is capable of in a dexterous way, may go a long way toward giving that one a wide reputation as a surgeon, but, in the long run, the surgeon is known by his results. The brilliant operator is bound to secure certain excellent successes, but, if he maintains his standing in the major work that comes to him, he can not give the cold shoulder to physiology and dietetics. They are his guiding stars. No definite line can be followed; he must cut according to his cloth, and he who lacks physiologic good sense, no matter how otherwise endowed, is no surgeon. But time will not permit me to go into the minutiae of the physiologic and bacteriologic laboratories, or into the very essence of physiology itself, and trace out its many ramifications. Such an exhaustive treatise on the subject can be found in any of the most recent text-books, in much better form and more acceptably than I am able to place it before you.

There is no reason why a surgeon should be a better physiologist than a practitioner of medicine, an obstetrician, a gynecologist, an oculist, or any other disciple of the many branches into which the profession has been divided. The very foundation-stone of the science of medicine is physiology; it must be, from its very nature, for surgery is really but a branch of medicine; and all who do work in our numerous specialties, must, by wise legislation, first attain the degree of Doctor of Medicine. Anatomy must be what some might term almost the right arm of the surgeon. But if this be true, physiology is the right

arm of anatomy. For, of what satisfaction is it to him who performs an operation, to look over his work, dress the wound, and then to see his patient die because the normal functions of the body go unattended? Is it not physiology that steps in here, takes up the work where the knife left off, and by intelligent management adds another success to the surgeon's credit? The knife in the most skilful hands the world ever knew can do only so much. It may relieve organs of the burden of diseased tissue, it may lop off unnecessary and useless members, but who ever heard of its replacing extirpated tissue of the stomach or intestinal tract, that could perform the functions of that lost? How long would our patients survive if, for instance, the entire alimentary canal were removed? Very true, indeed, sections of great length have been made from the intestinal tract, huge slices have been cut from the stomach, and the patient made an excellent recovery, but, if the physiology of the bowel be destroyed, or even too greatly interfered with, if the destruction of the glands of digestion take place, death comes inevitably.

Thus at the very elbow of the surgeon stands physiology, to warn the too venturesome operator that a halt must be called if he values his patient's welfare. By physiologic forewarnings we come to recognize malignant conditions interfering with alimentation and other functions, and to be forewarned is to be forearmed. These indicate to the surgeon, not only the position, but the character and extent of the involvement of normal tissue, thus enabling him to lend a helping hand to his greatest ally.

Great successes have been recently announced wherein the adaptability of the least remnant of the stomach, left after excision for malignant disease has been demonstrated. Schlatter (vide JOURNAL, vol. xxx, p. 265), Krönlein, Schuchardt, and Langenbuch have related to us their partial or complete gastrectomy, and the duodenum took up the task of playing stomach for the living example, and did it with success.

We do not know all of physiology as yet. Still, without paying it our most profound respect the most brilliant results of modern surgery would come to naught. Thus, with due respect to anatomy, to express myself more clearly, the surgeon must be equipped with two right arms; physiology first and anatomy second.

Were it not the fact that all bodies or engines of use must, in order to perform their necessary functions, be supplied with the proper elements to replace loss and repair damages, there would be very little for the surgeon to do beyond the mere exhibition of his skill and dexterity in handling the scalpel. Then all operations would be successes, and the surgeon would be the only truly great one among us.

The principle, that attention to the physiologic details of all operative work must ever be borne in mind holds good under all circumstances. The operator who willfully violates a physiologic principle, either in the immediate operation or in the post-operative care of his cases, will pay for it as dearly as he who goes contrary to any established surgical procedure. Infection of the intestinal tract, for instance, is as easily accomplished as infection of an open wound, and usually causes more disturbance to the patient than if the operated area became one solid slough. There is not enough attention paid to the ante-operative and the post-operative care of patients, especially

in abdominal surgery. One of the first questions asked by the nurse, when the operation is over, is, "Doctor, what may the patient have to eat?" Often, without waiting to consider the amount of resistance with which the patient may be endowed, the surgeon will say, "Oh, almost anything he wants," thus committing one of the grossest errors of which he is capable. So much has been said and written on the subject of dietetics, in connection with surgical work, and yet so little is accurately known, that it behooves each operator to himself become an investigator; and as his experience becomes greater with the increase of work, he will be enabled to lay down certain principles by which those coming after him may profit.

But the trouble is that as soon as the mere operative manipulation is a thing of the past, the patients usually cease to be an item of interest, except in a perfunctory way, and they are left to the tender mercies of a house physician, a nurse, or an undergraduate. Our surgeons are not physiologists. The matter of experimentation, carried out with strict adherence to scientific principles, is almost unknown to the great majority of them. The application of the simplest facts concerning diet and assimilation is disregarded. The condition of the patient, that element about which so much talk is wasted and so little is known, which we call "shock," is often overlooked. The fact that shock should enter into our considerations in minor operations is scarcely thought of; for to the mind of many an ambitious operator of today, such an element is unworthy of notice, except it be in connection with the invasion of the abdominal cavity. To him, an assault on the abdomen by a route which leads to the capitulation of some of its organs, is the acme of his desire. The terms "laparotomy," "celiotomy," "abdominal section," and lastly "vaginal section," are significant of such visions of greatness and reward to many men that they overshadow all other approaches to a career of usefulness and distinction. To be able to add name after name of successful sections of the abdomen to one's record, seems to be the height of the ambition of many with whom we come in contact. It is indeed lamentable that result cuts no figure. A cure often takes a secondary place in many long lists of statistics. The mere fact that the operated ones live to get on their feet and drag about in a half-dead manner for months and sometimes for years, perhaps with a post-operative hernia also, does not seem to have any influence on him who has his eye on the fee rather than on successful work. If the surgeon, if all practitioners, in fact, were better physiologists, if all physicians paid more attention to diet and assimilation, in the administration of remedies and the care of those to whom they owe their time and their best efforts, the surgeon, specifically, would not reap such rich rewards.

We can not overestimate the great value and importance, not only to one's self, but also to the patient, of a thorough knowledge of the subject of the administration of food, its treatment by the stomach, its assimilation and its final distribution through the proper channels. If we resolve the subject into a question of importance to the surgeon, it comes more closely to him when the matter of dietetics is considered in his care of patients after abdominal operations. One should not forget the all-important fact that the processes of waste occur continually. There can not be a moment of our lives, be we sick or well, asleep or awake, when such waste of tissue does not go on.

Repair must take place equally as rapidly, else we lose, so much in fact, that our life is endangered. For this reason regularly feeding the operated one at night is of as much importance as food by day. The vitality must be sustained by the proper exhibition of easily assimilable materials, either by the mouth or rectum, from the very outset. It is a grave error to starve the patient after section of the abdomen, a certainty which experience alone can teach us. It is a fact that must be taken into consideration that the functions of the vasomotor system are abnormally suspended by the shock sustained by one undergoing such a major operation. Consequently, the administration of foods of almost any character, until the equilibrium of the vasomotor system is restored, is most unwise. Usually we look for one to be fully out of shock in from twenty-four to thirty-six hours. Then the stomach is in fit shape to readily seize upon nutriment in small amounts, often repeated, and in a concentrated or predigested form. The intestines will be in readiness to assimilate and convert into proper solution the food administered, and the weakened heart will be buoyed and strengthened thereby, its beats will be firm and full, and of such a quality as to assure us our patient is in good condition.

We so often hear of and sometimes see patients who, it is claimed, die of exhaustion. What is this exhaustion? Too often, it may be, it is but the consequence of a succession of shocks, operative or otherwise, sustained by the individual, which so overpower and outweigh the recuperative ability that what little spark of vitality remains flashes out and they are gone. If this obtunded sympathetic system were taken into consideration at the time of extensive injuries to soft parts, and to the extremities, amputation and operation would not be so hurriedly advised and performed. Shock of operation added to shock of injury, is like feeding fuel to a flame that should be extinguished. Physiologic reaction rarely sets in where a system has been so ignorantly handled. If we would but stop and look into the book of the physical body, on the pages of which we read the rapid, weak, irregular pulse, the total insensibility to pain, perhaps the partial or complete loss of consciousness, the contracted pupil, the blanched face, the pinched, drawn countenance, the sighing respiration, the refusal of nourishment with the consequent craving for water, here we would see, as it were, an open page of the plainest most simple teachings from the book of physiology.

Physiology gives us at a glance the contraindication to operation, and it tells us how long, and to what extent we may pursue our cutting. Who would undertake operative procedure on a kidney without determining, by physiologic examination and investigation, the condition and amount of urinary secretions? It is the test-tube, the microscope and the germ cultivation, in the hands of the physiologists, that have made it fairer sailing for the surgeon, and have removed many obstacles among his onerous duties. Virchow, Pasteur, Koch and numerous others are they to whom the surgeons of the present owe their allegiance. These investigators have made it possible for their *confrères* to make unheard of assaults on man, and have opened up fields of labor for him which seem almost exhaustless. Under the guiding hands of these geniuses, the surgeon cuts here or there, taking out tissue, in one instance for examination, and in another for demonstration, then boldly hews to the line.

This is not the place to give directions for preparatory measures, when abdominal operations are under advisement. Still, I believe that if the patients be well and considerably nourished, even up to the limit of their capacity, before operation be undertaken, their immediate reaction and consequent convalescence would be a matter of much congratulation to them, as well as to ourselves. For it is no longer a question of doubt in my mind that the preparation of the patient immediately before operation has much to do with the outcome of the attack upon his organism.

It would be the height of folly for us to allow a subject to go under anesthesia without a careful examination of heart and lungs, and without having cleansed their economy by the ingestion of large quantities of pure water. Their wholesome, nourishing food need not be denied them until at least twenty-four hours previous to the time of attack. The water really aids greatly in the excitation to the discharge of gastric juices, dilutes the nourishing materials, and increases assimilation. So I would not starve a patient and then sluice him out with gallons of hot water, but I would follow the plan above, and see the operated one come from under anesthesia more quickly, with a stronger pulse, and with less shock than otherwise. I am convinced that one of the most formidable elements we have to contend with in abdominal surgery is that of intestinal flatus. I am also convinced that a great amount of the annoyance experienced by the patient in enduring it, as well as by the surgeon in endeavoring to combat it, might be eliminated by proper attention to the materials which enter the alimentary canal. Gaseous distention of the intestinal tract may occur equally as readily when we have prohibited the ingestion of food as when we have allowed something which will cause fermentation and consequent tympanitis.

I maintain in conclusion that the absolute observance of the physiology of digestion, the proper selection and careful and regular administration of articles of diet for hygienic results, and the study of such foods as are given for their therapeutic value, will minimize such disturbances and contribute greatly to the comfort and recovery of the patient. Without this due consideration for the complex human machinery and its conservation of energy; without a due allowance for the condition of heart, lungs, brain and kidneys, surgery will continue to be largely unsatisfactory both to surgeon and patient.

DISCUSSION.

Dr. L. DUNCAN BULKLEY of New York said that he was indeed pleased that this very important matter had been so ably presented. It was the greatest mistake to regard only the operative side of surgery. The surgeon should be the accomplished, thinking physician, and as such he could save lives which otherwise were often sacrificed. He stated that Dr. Joseph C. Eastman, in the presence of a number of physicians, had stated that during the past few years he had certainly saved some lives by the rigid employment of the plan of giving milk, warm, pure and alone, as just advocated by the present speaker in his paper. This he did, both before and soon after operations, and found that patients rallied and improved as never before. Dr. Bulkley wished to urge again, and most emphatically, the value of this method of feeding in connection with operations.

Dr. E. STUVER—This is a subject of the very greatest importance. In the selection of food for diseased conditions and especially in those cases where surgical shock is a factor to be considered, great care should be exercised to secure foods containing the greatest amount of tissue-building and force-producing materials, but such as will throw the least strain on the digestive and assimilative organs and at the same time

least interfere with free elimination. Since the great importance and far-reaching consequences of auto-intoxication have been recognized, greater attention is being paid to the excretory organs, and free elimination of toxic materials is now regarded as one of the most important matters in the management of any case. This practice is being followed by excellent results both in surgery and medicine, and many cases, that formerly, owing to improper diet and retained poisons, died, are now being saved.

Dr. PLUMMER in closing the discussion, said the subject was of great importance to him, and ought to be to every thinking physician. His attention had been called to the demand for food by those suffering from shock, by the manner in which dumb animals act when sick or injured. A sick or injured dog refuses food until such a time when his natural appetite calls for it—why should not the human body be supplied on the same principle? The employment of good sense and the following of physiologic teachings should guide us, then our results would be better and more satisfactory.

PHYSIATRICS, OR NATURE'S THERAPY.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY C. F. ULRICH, A.M., M.D.

WHEELING, W. VA.

Nature is, without doubt, the best, the most successful physician, when she is permitted to have full sway and her mandates are obeyed. Almost every disease, every ailment, every departure from the normal condition, exhibits a tendency to recovery. In the human body, as in that of the animal, there exists apparatus for the removal of elements that disturb the healthful working of the internal machinery; such as the depuratory system, i. e., the bowels, the kidneys, and the sudoriferous glands. The work of depuration is not confined to the above named organs, neither is that their only function, since the intestinal tract is largely concerned in digesting the food and preparing it for assimilation, and the system of sudoriferous glands serves to cool the surface of the body during excessive heat and in fevers. The greater number of diseases that afflict man and sometimes cause his death will result in recovery, if circumstances are favorable, and if there is not some unnecessary interference by the patient, his family, or an unskilful physician. I wish not, however, to be understood as insinuating that the physician is a superfluous piece of furniture and should be abolished. Far be it from me to assert any thing so heretic. I will stand up for our beloved profession at all times and under all circumstances. Yet I should be very happy could I live to see an expurgated edition of the medical calendar. In another part of this paper I will endeavor to show how much benefit the skilful, conscientious physician can confer upon his patients, even though he does not cram them daily with poisonous or deleterious drugs; or cut them open, remove certain parts from their bodies, and sew them up again, as the tailor does in repairing an old garment that is wearing out. Unfortunately, he can not imitate the tailor, who inserts a new piece where he has removed the defective part. He can not replace the organ that has been removed by inserting a new and healthy one, thus preserving the natural function. The body, after such a mutilation, necessarily remains an imperfect machine. The occult principle which we call nature or vital force, is the chief motive power in the development, the growth, and also the decline and death of the human body. It may seem somewhat paradoxical to assert that the vital force is instrumental in the induction of decay and death. Yet it is ap-

parent to every careful observer that all vital processes are self-limited, and are continually undergoing changes. From decay and death are developed the elements of a new life, which, in its turn, must submit to the same decline and final dissolution.

We will consider in this paper only the pathologic conditions which result in what we call disease, their detection and their possible cure. Animals and savages, or, as I prefer to call them, children of nature, are not subject to as many diseases, nor to so great a variety of them, as civilized people. Animals die because they are killed and eaten by others, or are destroyed by man, for various reasons. Otherwise they mostly reach the period of life allotted to them by nature's laws. Diseases exist principally among animals that have been domesticated by man, and consequently do not live in a state of nature. The children of nature, or savages, of whom the aborigines of America may be regarded as an average type, are usually born healthy; grow up without requiring much care; and pass their life in a state of health. The men hunt, fish and carry on war; the boys are trained in all the exercises pertaining to war and the chase, spending most of their time in the open air. The women feed and rear their children, cultivate the soil, make the few garments worn and prepare the frugal meals for the family. In this simple manner they pass their lives, very seldom suffering any disturbance of health. When they have accomplished the period of life allotted to them, they quietly lie down and die. This description applies to them when they lived in their native simplicity, before the paleface—the man of civilization—came among them, furnishing them with firearms, that they might have greater facilities for mutual destruction, and with firewater to advance their powers for self-destruction. He inoculated them with hitherto unknown diseases, drove them from their forest homes into less favorable regions, where they pined away, being no longer children of nature. In speaking of the children of nature, their mode of living, their healthy condition, their painless death at the end of their allotted time, I must not be understood as commending the barbarity, the ferocity, the utter disregard for human life that characterizes many of them. Nor would I hold them up as examples to civilized people in anything except their obedience to the laws of nature, which was not due to their having studied hygiene, or having observed sanitary rules on principle, but which arose simply from a natural instinct and an utter ignorance of the artificiality and the conventionalities of civilized life.

I have merely introduced this as an illustration of what will happen when the laws of nature are obeyed, be it from instinct, as among the savages, or as the result of intelligent teaching. Now what is the reason that in civilized countries so many die early, or drag on their miserable, unhappy lives, sick, weak and helpless; requiring the service of a physician from day to day, and from year to year; swallowing incalculable quantities of medicine; then, at last, when they have spent a joyless, painful life, unwillingly entering upon their journey to the unknown Land of the Hereafter? It is because their parents, as well as their more remote ancestors, have lived contrary to the laws and dictates of nature. Nature gives us the sensation of hunger that we may take our food in proper season, in suitable quantities, and of a kind to promote strength, health and long life. Thirst is given us that we may take the necessary liquid to

preserve the fluids of the system, to keep the blood in a state suitable for circulation, so that it may carry the necessary nutriment to all the organs and tissues of the body that have been wasted by their functional activity, also to carry off the worn-out parts that are no longer of any service, but, like foreign substances, set up an irritation and cause disease. When man has exerted himself, either in labor or in amusement, he is overcome by lassitude, which serves as a warning that he should retire to rest in order to recuperate his overtaxed powers, and enable his tired brain, his strained nerves, and his overworked muscles to regain their tone, so that, next morning, refreshed and strengthened, he may resume his daily occupation. While he is thus resting from the toils of the day—whether of the brain or muscles—the internal organism, the digestion, the assimilation, the rebuilding of the wasted and worn forces, both animal and intellectual, are being repaired, for that work goes on, even while the man or woman is taking rest in slumber. In this way his powers are strengthened and his endurance prolonged. To eat when we are hungry; to drink when we are thirsty; to sleep, or at least rest, when tired; these are the great, powerful recuperative agents which are employed by animals, savages, or children of nature, without thought, without reflection, just from natural instinct, undisturbed by the fashions of a modern civilization. As a result of this mode of life, they are afflicted by few diseases, and an attack of illness is a rarity. Unless killed by others, they die of senility, after having gone through the ordinary period of their life.

How is it with the people who call themselves enlightened? Do they eat when they are hungry? Do they select the healthiest, the most nutritious diet? Do they take it in such quantities as will best preserve their health and the strength with which nature has endowed them? Do they drink merely to quench natural thirst, the fluidity of the blood, the natural softness and pliability of all parts of the body? Do they rest when they are fatigued, and retire to sleep in order that the tired organs can recuperate and the internal mechanism, quietly and undisturbed, prosecute its usual work of recuperation? No. They do nothing of the kind. They pay but little regard to nature, or her laws. They take no cognizance of this beneficent healing power. They live altogether in a conventional manner; eat at stated hours, fixed by fashion, three, four or five times a day, be they hungry or not. The nutritious quality of the viands is not considered. They tickle the palate with all sorts of delicacies, which tempt them to take more than is necessary for the growth and preservation of the natural powers. This excessive feeding causes disturbances in the digestive apparatus; constipation or diarrhea, with catarrhal inflammation. Now, when nature rebels against this abuse, and a loss of appetite ensues, they excite and stimulate the stomach with all sorts of condiments, causing irritation, with a temporary increase of the gastric fluid. But now the inevitable takes place; the stomach and digestive tract lose their power through over-stimulation, just as the tired horse, when beaten by the driver, is goaded to greater exertions, until finally exhausted, it is unable to go any farther, and falls to the ground either dead or unfit for further exertion. The civilized man drinks all sorts of stimulating and exciting beverages, which increase, instead of quench, his thirst. Should thirst, however, fail, because an excessive quantity of the

beverage has been taken, it is stimulated by highly seasoned food. The brain is then excited; wit and repartee fly in brilliant coruscations; restraint is dissipated; and men who by nature are sober, dignified, thoughtful and modest, become wild, irrepressible and regardless of the opinion of others. The color is heightened; the blood rises to the head, producing a congestion of the brain. The period of healthy sleep passes away; and when at last the reveller is overwhelmed by drowsiness and yields to the persuasions of Morpheus, he does not enjoy the healthy sleep that recuperates the worn-out powers of mind and body; but sinks into a semi-coma, frequently tormented by awful nightmares and visions of horror, to awake later in the day with a brain-splitting headache, which disqualifies him for a satisfactory performance of his duties. This is the history of many a banquet partaken of by enlightened and highly cultivated gentlemen in civilized countries. Of course, this description does not apply to every social gathering and banquet in our times; but I have given an extreme case, to show to what our modern fashions sometimes lead us. But without doubt, we all violate nature, more or less, in our mode of living; in eating, drinking and taking our rest. Even though we are fully enlightened as to the danger to health and life, we are dragged into the vortex of fashion, and find it difficult, if not impossible, to extricate ourselves from it. The health-, strength-, and life-giving sunlight is lost to us in a great measure, because we spend much of that time in sleep. We live, we pursue our avocations and our pleasures by artificial light, in closed rooms, excluding the pure air which is of such importance to us in the preservation of health and strength, both of body and mind; eat unhealthy food; drink brain-destroying beverages. Is it then a wonder that so many have pale, sallow complexions and weak, excitable nerves, which cause them to toss about in the bed, unable to sleep; to sit at the table without appetite; to suffer fatigue from the least exertion; to have the doctor in the house half the time?

Let us see now what the average physician, the mediocre, who regards his calling as a mere trade out of which he makes his living, will do when called to such a patient. Does he investigate the previous history, by the help of which he could discover the cause of the pathologic condition, thus having before him a picture of the origin, the extent, the course, the probable end of the disease, which would serve him as a safe guide to find ways and means to combat the evil? No. This would be too laborious and perhaps a little beyond his acquired knowledge. He may even fear to offend the patient or his family by trying to know more than they are willing to communicate, which would endanger his prospects of future emolument. He, therefore, treats the disease symptomatically, administering a variety of drugs, mostly of a poisonous nature. Without inquiring into the cause of pain, he gives anodynes, such as morphin, cocain, etc. For asthenia he gives strychnia and other stimulating drugs. For high temperature he gives depressing medicines, without inquiring into the cause of the fever or endeavoring to discover whether it is not the effort of nature to rid the system of some offending substance, in which case a little water, externally and internally applied, would assist nature and relieve the sufferer. It is astonishing what horrible doses are administered by the superficial physician, converting the stomach and alimentary canal into a chemic lab-

oratory, thus gradually sapping the foundations of life.

But let us leave this dreary theme, and see what the well-informed, the sensible, the industrious, the conscientious physician will do. He investigates the hereditary tendencies, the surrounding circumstances that may have exercised an influence in the causation of this particular disease. He does this, regardless of the danger of giving offense, although he employs tact in the pursuit of his investigations. After having made all the necessary inquiries, he enters upon a careful, thorough, and if necessary, prolonged physical examination in order to be sure of his diagnosis before entering upon the treatment. If he discovers that nature is too weak to remove the evil, he assists with innocuous remedies, or even with strong ones, if this is shown to be absolutely necessary. But, if he finds that the natural powers are sufficient to accomplish the work, he does not intervene with a disturbing hand, but permits the healing power of nature, *vis medicatrix nature*, to have full sway.

In the year 1866 I was called to a little girl, two years old, that was laboring under fearful convulsions. The physicians in that section, none of the brightest, had always ordered hot baths and anodynes for convulsions, regardless of the cause. When I arrived, the child was seated in a hot bath and had taken several doses of paregoric. The spasms had lasted for an hour when I arrived, and were getting worse instead of better. I inquired if the child had been subject to such attack, to discover if it were a case of epilepsy. The answer was negative. Had it suffered from constipation or diarrhea? No, it had never been sick. Had it eaten anything that might disagree with it? The parents, who were intelligent people, said they knew of nothing the child had eaten that could have put it in such a state. On further examination I found no fever, no pulmonary trouble, no kidney or bladder disturbance. But the epigastrium was terribly distended and hard, giving evidence of an extremely overloaded stomach. I decided to empty it at once, as no time was to be lost. Owing to its distension, the stomach was incapable of peristalsis. Here, nature being unable to act, assistance became necessary. I administered a simple emetic, followed by a cup of warm water, which induced copious emesis. It was perfectly astounding to see what came out of that poor, afflicted stomach; bread, potatoes, cabbage, sweet potatoes, beef, ham, pickles, dried apples, etc. There was enough in that infant's stomach to serve as a full meal for a hardy laborer. On my inquiring, with some degree of acrimony, how this happened, the cook, a large, fat, colored woman, acknowledged that when she was eating her dinner in the kitchen, she seated the child on the table and encouraged it to eat of everything, enjoying the sport of seeing the greediness with which the little thing swallowed all that was given it, never thinking that it would do the child any harm. I gave it several cups of warm water, until it ceased vomiting and the stomach was completely cleaned out, without the use of the stomach-pump. No other treatment was necessary; the convulsions never returned.

I hope you will not be offended if I bore you with another example. About twenty-eight years ago, an old German shoemaker came to me and said his wife was terribly afflicted with her water. Every attempt to urinate caused her such intense pain that she had to scream out. She could not bear the least touch

about her sexual organs without the most excruciating pain. Dr. A., he said, had treated her with washes, ointments and internal medication, for almost a year without ever examining her. (Dr. A., by the way, posed as a gynecologist.) The old man said: "I have made the doctor and his boys ninety dollar's worth of boots and shoes, and he holds me in his debt yet, while she is getting worse all the time. Now I want you to come to my house, examine her carefully, and either cure her or kill her, for we can't live this way any longer." On examination, I found a caruncle at the orifice of the meatus urinarius, very red, about 3/16 of an inch in diameter, attached by a stem, looking very much like a ripe currant. It was extremely sensitive to the touch, causing a scream every time the finger came in contact with it. I took a pair of scissors, curved on the flat, out of my pocket-case and cut it off, touching the place with a stick of nitrate of silver. The woman was cured, no further treatment being employed, except a simple alkaline remedy to correct the acidity of the urine, which only had to be continued for a short time.

I could relate very many cases where the simplest remedies, judiciously applied, brought about the most astonishing results. Many a time, after the routinist had tried all his best skill in giving strong medicines, and employing heroic treatment without benefit; yes, even with great injury to the patient; the hygienic physician, with the simplest remedies, has accomplished the most surprising cures. The physician who has more regard for the welfare of his patient than for his own reputation as an elaborate therapist, will post himself thoroughly in physiology, or the natural working of the inner machinery of man; with pathology, the disturbance of this same machinery, which causes what we designate disease. Is he fully cognizant of and well instructed in these two branches; does he possess good sound sense, acute and well-practiced powers of observation, intimate acquaintance with the best and safest remedial agents, a mind quick to take in the situation, and fertile in expedients in cases of emergency; and, in addition, an honorable and conscientious character? If so, then the patient may safely trust his health and life to him. He will not poison him nor undermine his constitution, but will, if the disease is not a deadly one, restore him to health in the shortest possible time, and with the least expenditure of medicine. For he relies upon nature and her diversified powers, as far as she is capable of doing the work herself, only intervening with artificial remedies when nature is too weak or perverted. Let not, however, the layman be led to imagine that, because Nature's Therapy is recommended, he can dispense with the services of the physician; for, without such aid and advice, he would not only fail, but, by his ignorant interference, he would pervert the natural processes, and the patient would be in a worse condition than before. Neither must the layman be permitted to think that the man who does not cram his patient, daily and hourly, with strong and poisonous drugs has failed in his duty and is not entitled to reward. For it is a self-evident fact which should, by every possible means, be impressed upon the general public, that the physician who can restore his patient to health without making his body the receptacle for great quantities of destructive poisons, is a much more intelligent and trustworthy medical adviser, and will more surely earn his reward, than the man who, without investigating the nature

of the disease, fills the poor sufferer with strong medicines, regardless of the mischief this course may do in undermining the health and interfering with the future comfort of the victim of such heroic treatment.

The Therapy of Nature, of which I have given a feeble and imperfect picture, will not suffice for all cases. Nature can not remedy all errors nor repair all lesions, although a large majority might be prevented if man would always live according to nature. Yet, since this is not the case, it is essential that other branches of therapeutics should be closely studied and skillfully practiced. Heroic treatment is sometimes indispensable, and the surgeon's knife must now and then be called into requisition. Yet the study of nature and the employment of her methods in medical practice should always hold the highest place in our therapy.

HYGIENIC MANAGEMENT OF CHILDREN.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY A. E. MILLER, M.D.

NEEDHAM, MASS.

This subject is so broad that one hardly knows where to begin. To have children as perfect as possible we should begin several generations back. The Mosaic statement, "visiting the iniquities of the fathers upon the children even unto the third and fourth generation," is a physical fact, which applies no less to the mothers than to the fathers. If parents would have the best possible children, they should get themselves in the best condition previous to the begetting of the children.

It is a humiliating fact that the most important act of a man's life is too often accidental. In the breeding of the lower animals the greatest care is used. If a farmer is breeding for milk, beef, or beauty, he selects the parent stock with the greatest care, with an eye to the particular point to which he is building. It is interesting to note with what care the horse-breeder who is breeding for speed and other fine points selects the animals from which he is to breed. Not only must the sire and dam be all right, but he looks up the pedigree for several generations back to make sure that no trick or taint of blood has existed in the progenitors which may show in the later generation. He is particular that both parents be in the best possible condition at the time of conception, and that the mother be kept in good condition during the period of gestation.

With care, improvements may be made in all breeding. Note the increase in speed of the horse. What would have been considered a fast horse fifty years since would be thought a slow animal now. Even with the hen what wonders have been wrought, both in egg production and marks of beauty. The same is true with fruits and flowers. What large, fine, delicious flavored fruit has been developed from the small, inferior wild progenitors. With flowers what delicate tints and rare perfumes has intelligent cultivation produced.

With all these facts before us as object-lessons, is it not humiliating to see so little improvement in the human animal? Small, deformed, diseased children may be seen all around us, who, if they live, will develop into inferior men and women. What are we as a body of thinking, scientific men and women doing

to remedy this great evil? Perhaps you will say: What has this to do with the management of children? But how can we manage children unless we have them to manage; and it is quite important that we have the right kind to begin with. Take a wild crab-tree, and by judicious pruning, we can improve its appearance, but the result of our labors will be unsatisfactory. On the contrary, take a fine, improved Bartlett pear-tree and a little care will yield us in return the most delicious fruit.

Having a good child to begin with, the first thing to claim our attention is the food. The most natural food is the milk of the mother. But to have this food in a proper condition the mother should be in good health, properly nourished, and free from annoyances which will excite and irritate the nervous system. Milk producers understand the great importance of proper food and drink in determining the quality and quantity of the milk, and also the importance of quiet, gentle treatment for the cow. The same is true of the nursing mother. Plain food and drink with gentle exercise and freedom from nervous excitement will give the best results. It is well known that the improper food and drink of the mother at irregular hours is the cause of many of the ills of the nursing child. Often a fit of anger on the part of the mother will so affect the milk as to cause disease of the child. If from any cause food other than the milk of the mother is to be given to the child, great care should be used in selecting and preparing it.

A great variety of substitute foods have been put upon the market, many of which are very good. I have seen fine, healthy children, whose principal food was Malted Milk or Mellin's Food or some similar preparation. As a rule, I prefer the milk of a healthy cow. The specific gravity of human milk varies from 1.028 to 1.036; that of cow's milk 1.028 to 1.034. The chemic composition of milk is:

	Fats.	Sugar.	Proteids.	Ash.
Human Milk	3.5	6.5	1.6	0.25
Cows' Milk.	3.9	4.7	3.7	0.7

As will be seen by the analysis, the milk of a good cow is too rich in proteids and deficient in sugar for the young child. We usually add an equal quantity of soft or distilled water, and also a little sugar. If the quality of the milk is poor in casein and butter, we add less water. If it is rich, as in the case of the Jersey cow, we add more water. As the child grows older, and sleeps less and exercises more, an increase of proteids is demanded for the development of the bones and muscles, consequently we add less and less water, until the milk may be given undiluted. As a rule, good milk or some of the prepared foods will be sufficient for the first year.

Many mothers derange the digestive organs of the child by giving it bread and other starchy foods too young. As the salivary glands of the infant are not sufficiently active for their secretions to aid in digestion for the first six months, and as the saliva aids in converting starch into sugar, it is evident that no starchy food should be given until after this period. After the salivary glands are sufficiently active the child may have bread and mashed potatoes in moderation. When the teeth are sufficiently developed to masticate the food, fruit and vegetables may be given with advantage. As a rule, the child should have no meat until after the first year. Mothers and nurses often feed children meat when only a few months old. This makes them more excitable. My observa-

tion has been that children who are not fed meat until a year or two of age, are less excitable and more healthy, other circumstances being the same. Strong tea and coffee often make the infant wakeful, fretful and irritable, and sometimes cause constipation; they may be taken through the mother's milk or may be given to the child direct. Many nurses let the child sip strong tea and coffee from their cup when they are drinking it: this should never be done; it is one great cause of nervousness in the child.

Regularity in the hours of feeding is important and should be established at an early age. In rare cases the child may be fed every two hours; usually every three hours is better, and as the child grows older and is able to take more food at a time it may be fed less and less often, but all changes should be regular. Cleanliness and clothing, except with the very ignorant, usually receive proper attention.

The temperature of the rooms of the mother and child should be kept even. Some nurses let the room get too warm, then a free perspiration is produced which makes the patient more sensitive, and with the cooling of the room or the admission of fresh air, a chill is felt. The room should be large enough that a proper supply of fresh air may be admitted without the patient feeling a draught. A cubic space of 1000 feet is desirable for each individual. The average composition of pure atmospheric air per cent. per volume is O 20.96, N 79, CO₂, .04. In addition, there may be traces of ammonia, mineral salts, and organic matters. A healthy, average sized man, at rest, breathes at the rate of seventeen respirations per minute. At each respiration about 30.5 cubic feet of air pass in and out of his lungs. The composition of this respired air is roughly estimated as follows: O 16.96, N 79, and CO₂ 4.04 per cent. The air in the lungs loses on the average 4 per cent. of O and gains 4 per cent. of CO₂, while the N remains unchanged. We should never allow the air in the room to contain more than 6 volumes of CO₂ in 1000. The Boston building law requires every hall, auditorium or room of every building used as a schoolhouse, factory, theater or place of public assembly or entertainment, to have in continuous operation, while occupied, a system of ventilation so contrived as to provide 50 cubic feet per minute of outer air for each individual and for each light other than an electric light.

Sunlight is essential to the healthy development of the child. Plants and animals deprived of sunlight become pale and sickly. The florist understands the importance of sunlight in giving the finest tints to his flowers. Many a child is pale and sickly because it is kept indoors and deprived of sunlight and pure air. If the weather is too severe for the child to go out, give it a sunny room for a playroom. If too young or too feeble to play, keep it where the sun will shine on it a part of the time at least. The love of liquor, which leads to drunkenness, is often born with the child, stamped by the mother during the period of gestation because of the bitters and other alcoholic mixtures which she takes for fancied ills at this time. It may also be acquired by the dosing with cordials, essences, slings, etc., which are often given during the period of infancy. Many nurses administer hot whisky whenever the child has indigestion or is a little worrisome. In some cases the family physician is at fault in recommending hot whisky for colds and brandy for intestinal irritation. These remedies become so attractive that the young

man has his sick spells very often, and at times he is in such mortal fear of the difficulty that he takes the medicine to ward off the dreaded malady. Men have often told me that they had no love for liquor, in fact did not know the taste of the different alcoholic mixtures until it was prescribed by the physician. A young man who became a confirmed drunkard told me not long since that the family doctor was the cause of his downfall. When quite a young man the doctor, on meeting him, would often say, "Fred, you don't look well," or, "you have a bad cold; come into the drugstore and have a little brandy with me." Parents often complain that children are deceptive, disrespectful and falsify. Is this to be wondered at, when, as in some families, the first lessons given the children are in this direction? Parents often dispute and call each other harsh names in the presence of the child. Soon the child thinks it can use the same language to the parents that they use to each other. The mother, in the presence of the child, talks about her neighbors and declares that she never wants to see them again. But when they do call she is all smiles, and urges them to stay longer and to call often. These are lessons which soon bear fruit in the child. As to falsehood, how often the mother says when administering bitter medicine to the child: "This is good, it is sweet; take it, just take this one spoonful and you need not take any more." In an hour a similar dose is repeated with the same story. Will the child believe the mother after this? If the mother can lie to and deceive the child the child will practice the same on the mother. Perhaps an unwelcome caller is seen coming and the child is sent to the door to say, "Mother is not at home."

The brain should not be developed too rapidly. Many a child has the brain developed at the expense of the body. The first care should be to build up a good, strong, healthy body. As a rule the child should not be sent to school under six years of age. Kindergarten exercises, under the care of a sensible teacher, may begin much earlier. In most of the public schools the children have too many studies and too long lessons. Many girls in the high school break down from excess of mental work and become invalids or fill premature graves. Many a fond mother mourns the loss of a brilliant daughter and sees the folly of overcrowding in school work when it is too late. Brilliant mentality requires an active, healthy brain which must have a strong body to support it. A healthy, growing tree must have good roots. Good digestion is as important to the active growing child or to the pupil in the public school as good roots are to the tree. True, some children who have slender bodies make fair progress in school work, but with a good body their record would be much better.

If parents and guardians would give more attention to the strong, healthy development of the body of the child and less to the fashionable follies of life we would have a much better class of men and women.

DISCUSSION.

Dr. E. STUVER—No question merits our earnest attention more than the one so ably presented by the writer of the paper. If we can not go back a couple of hundred years, as recommended by Dr. Oliver Wendell Holmes, to lay a solid physical foundation for our own children and those who come under our professional care, it is at least our duty to use every means in our power to assist them in attaining a strong and symmetric physical and mental development after they do arrive in the world. In the first place I desire to protest in the strongest possible manner against the deleterious practice of administering stimulants and narcotic poisons to infants. In many cases

young children suffer from thirst, and plain cold water, which, by the way, should be given regularly, will do them more good than all the paregoric or soothing cordials that can be given to them. Regularity in feeding is one of the most important matters in securing the healthy development of children, and when this course is adopted immediately after birth it is very easy to follow, and in my experience has given most excellent results. If with regularity is conjoined the proper kind of a dietary, an abundance of pure, fresh air, outdoor exercise and plenty of sleep, children thrive surprisingly. Nor are the good effects confined to the children alone, but the parents, through uninterrupted sleep at night and freedom from worry and care, largely share in the beneficent results. Give the children pure food, pure air, plenty of exercise and sleep and protect them against stimulants and narcotic poisons and we can confidently look the future in the face with the assurance that they will develop their best possibilities.

MANGANESE IN THE TREATMENT OF DYSMENORRHEA.

BY CHARLES O'DONOVAN, A.M., M.D.

BALTIMORE, MD.

When the athletic young woman of the present day first made her appearance and began to make the fad popular, physicians thought that with the changed conditions of her life would come such an improvement in her general health that most of her minor ailments would disappear of themselves. Of these I wish, for the present, to consider dysmenorrhea as the chief, and the one that appeared to present the best hope of cure. Sermons innumerable had been preached against the high-heeled shoes and the tight lacing of the generation of girls just gone by, attributing to these pernicious influences most of the ills that afflicted women, and now that no heels, and waists of nature's own proportions had become fashionable, it was reasonable to suppose that the attendant train of evils would also disappear with their causes. But it did not follow; in spite of riding, walking, tennis, bicycling, and finally golf, our girls continue to suffer, as did their mothers, from menstrual pains, frequently of great severity.

When tight lacing was in vogue, the cause of this dysmenorrhea was so often some displacement of the uterus, that many claimed for the pain a purely physical origin, and endeavored to relieve it by correcting the malposition mechanically. Retroversions and retroflexions were relieved often by one or other of the many pessaries; antelexions were operated upon in many ways, sometimes with complete relief, sometimes without ameliorating the pain in the slightest possible degree.

With the development of the athletic age it was discovered that bad flexions became much less common, but the frequency and severity of dysmenorrhea were but little changed. Then came those who ascribed most of the pain to ovarian influence, and the fury for removing ovaries spread over the land. Against this insanity arose everywhere the protests of conservative physicians who thought it better to give some time to treatment of these cases before resorting to the knife. The operating gynecologists seemed to forget that medicines existed, and insisted upon surgery as the only hope. Statistics showing the innocuousness of the operation were offered in support of that view, losing sight of the importance of the ovary to the female economy. Many physicians, however, held back, preferring to give drugs a fair trial, and too often it was found that medicines relieved perfectly cases that had been about to lose their ovaries, but which for some reason had slipped out of the

hands of the operators. Cases which submitted to vaginal examination revealed often no discoverable physical cause for the severe pains of each menstrual epoch, and were frequently benefited to such an extent by medicines that no further question of operation was possible. Many young women refused examination altogether and were given remedies empirically, because similar sufferers had been so relieved, and often with complete success. So we may say safely now that young women are not likely to be called upon to select one of several serious operations before a thorough course of medicine has been tried.

Too many drugs have been vaunted as specifics in these disorders, showing by this that no one will give relief always. Sedatives and narcotics will relieve temporarily, but at the expense of leading in many cases to a confirmed habit, so that opiates and the coal-tar derivatives should rarely be used, especially as our modern women are very cunning and soon learn to use drugs of themselves without asking for a physician's leave. If this is to be effected, we must provide them with what is harmless. This excludes also alcohol, with which thousands of women are drugged into semi-consciousness every month.

The great majority of cases of dysmenorrhea occur in anemic young women, who require iron, and frequently under its influence they regain their proper condition of blood and need no other medicine. This remedy, persisted in for a reasonable period, say six months in many cases, to be used again if the same symptoms reappear, is the most important in the treatment of this ailment. But there are many cases in which iron seems not to be required, from the excellent general health and the rich florid color of the skin, and yet the return of each menstrual period means a new period of agony to a woman who is apparently in perfect health. Between the periods nothing is complained of, but every month the trouble recurs, and each month it grows worse. Such cases are met with every day, in all classes of society—among the neurotic young women of high station and luxurious surroundings as well as among sewing women or worn-out shop girls. Nourishment and exercise have no effect upon the dysmenorrhea; they suffer as well during the summer holidays at the seashore or in the country as during the winter fatigues either of social gayety or of paid labor.

The cases to which I refer do not require iron; and if it is given to them experimentally they derive no benefit from it, or may even be made more uncomfortable. In very many of these cases I have obtained excellent results from the use of manganese, generally used alone, but sometimes with viburnum. I speak now of virgins, who should never be subjected to the indignity of a vaginal examination except as a last resort and after a fair trial of drugs. How these women escape becoming drunkards is a mystery to me, for they invariably have been taught by sympathizing companions that some alcoholic intoxicant, oftenest gin or whisky, is the only available medicine for relief at such times: It does not relieve, except in the sense of deadening their sensibility and thus giving time for the dysmenorrhea to pass away. In treating these cases, I have tried a number of remedies, but have reached the conclusion that manganese is to be depended upon far more than any other, and often gives such results as seem truly remarkable. I have today seen a young woman, otherwise healthy and strong, slender but excellently proportioned, whose

activity and energy denote apparently perfect health, but who used to spend the first day of her period every month in a perfect agony of pain, tossing from side to side in her bed, vomiting every few minutes, and crying out with each return of her cramp. Alcohol gave her no relief till she was stupefied, and various remedies that she had tried were useless, or so powerful that she would require a couple of days to recover from their effects. She obtained perfect relief by taking pills of manganese, iron and hyoscyamus for a week before each period, and became so well that she ceased treatment, and paid for her carelessness by a return of her dysmenorrhea nearly as bad as ever. But it may have been the iron or the hyoscyamus. She had been given iron freely before the manganese was added, but without result, and the amount of hyoscyamus was too small— $1/3$ grain of the extract—to have any such effect. In each pill were two grains of black oxid of manganese, and this I consider the efficient drug.

This case is but one of many that I could quote from notes, few as bad, but many approaching it in severity, that I have watched for longer or shorter periods during the past ten years. More extended records can be found in papers on the subject that I have published in the *Medical News* of April 6, 1889, and Nov. 27, 1897, where several very convincing cases are related. The recent histories of these young women continue to bear out the good opinion originally obtained of manganese, for it has proven itself to be a remedy that does good continuously in such cases as it benefits, not losing its effect with prolonged use but, on the contrary, becoming more and more satisfactory in each succeeding month.

The habit of dysmenorrhea tends to intensify itself in neglected cases, growing worse monthly, and harder to relieve; beginning early in the menstrual life and rapidly fastening upon the sufferer such a fear of the recurring pain that life becomes a burden. For this reason it is advisable that treatment should be instituted at as early a period as possible. Dysmenorrhea does not disappear of itself; it always grows worse if let alone. Therefore it is very bad practice to put off the mother of a young girl whose early periods already cause her great pain, by telling her that time will bring relief. It will not; on the contrary, we have every reason to believe that each month will, if let alone, be worse than the last. But the ardor of the operating gynecologist has been such that many mothers, from fear, refrain from mentioning their daughters' ailment. It is in such cases that manganese offers the best means of relief and cure. It is extremely efficient in those young women whose dysmenorrhea seems due to functional neuralgia, beginning almost with the establishment of menstruation. If administered early in the course of the disease great relief is experienced; if persisted in, the habit is, in many cases, readily broken up and the health of the sufferer saved from impairment. Such young girls should never be examined, even by the rectum, unless there is very positive evidence of serious local inflammation, until manganese has been given a full trial.

After the habit of dysmenorrhea has been fully established for years, in older women, it is a more difficult matter to destroy it, but in many instances it can be done. The most important thing to remember is that one should not be too soon discouraged. If a trifling improvement can be seen after two or three months of constant use of manganese, it means that

great relief can be given by it. One need not despair until four or five periods have passed with no benefit from the drug. In many cases it is not necessary to wait so long. If the case is a suitable one, the first succeeding period will be notably easier, and after that little or no pain will occur during the administration of the remedy.

Manganese is offered in various forms, but I have found the black oxid the most satisfactory. It should be given in doses of two grains, by itself or in combination with iron or other adjuvants, about an hour after each meal. It may be used for an indefinite time without any ill effect, and should be given constantly until its efficiency or inefficiency shall have become manifest. If benefit is obtained at once, I then order it to be taken for two weeks before the next period; if that has been nearly painless, it is given during one week before the following period. In successful cases, this is usually enough, and taking the drug during one week just before menstruation insures a painless period. No deleterious effects of any kind follow its use in this manner. It should be continued indefinitely; usually after a few months the patient feels cured and stops taking the pills, but this is apt to cause a return of the dysmenorrhea, especially in those women who have suffered for any length of time. In young girls the habit seems to be more readily destroyed, and the general systemic improvement renders the cure permanent. One must not expect cure, or even relief, in all cases that present themselves, for many will obtain no benefit whatever, but many others will be benefited by manganese after other remedies have been tried unsuccessfully, and when there seemed nothing left to hope for but the sacrifice of the ovaries or some other surgical treatment.

10 E. Read Street.

SOME EXPRESSIONS OF ABORTIVE ATTEMPTS AT INSTRUMENTAL ABORTION.

BY FRANK A. STAHL, M. D.

Instructor of Obstetrics, Rush Medical College.
CHICAGO.

Without doubt, of all the cavities of the gyneccean body not intended by nature to be invaded with impunity, the impregnated uterine cavity enjoys the distinction of being the most often explored. This is so, not only because of the many delicate perplexities oftentimes presented for differential diagnosis, but also because of the many other less scientific, but ethically regarded purposes.

Most often abortion, with its sequelæ, follows these instrumental invasions. Not seldom, and in the hands of skilled operators, these attempts and even repeated attempts to induce abortion prove abortive, much to the surprise of the patient and discomfiture of the operator; the reaction caused by the attempts passes off and pregnancy continues. In a few cases trauma and infection are caused by these attempts, yet pregnancy continues, but sooner or later and before full term is attained, dangerous inflammatory and septic reaction follow from these traumatisms and infection, which require immediate interruption of the pregnancy to preserve maternal life. Some five years ago¹ I had such a case, where there was a history of repeated instrumental invasion of the impregnated

cavity, with traumata and sepsis, but without interruption to pregnancy. To save life it was necessary to interrupt the pregnancy.

Case 1.—Mrs. X., 5 ft. 6 in., 125 pounds, housewife; temperament nervous, easily hysterical. First pregnancy, normal labor, boy now 8 years old; second pregnancy, normal labor, boy now 6 $\frac{3}{4}$ years old. Subsequent pregnancy successfully evaded until present case, when in August, with usual subjective symptoms of menstrual expression, there was no sign of menstruation. To persuade the flow the patient used steam and hot water, sitz baths, douches, much and various medication, all without the hoped for result. Growing desperate, two weeks after regular period a button-hook was employed (Fig. 1A), the immediate result being some flow, ceasing after ten minutes, accompanied with backache and bearing-down pain of some two hours' duration, but gradually subsiding. One afternoon, coming from a professional consultation, during which a sound (Fig. 1B) had been passed and actively moved about, the patient, clad in light summer garments, was caught in a severe rainstorm and thoroughly chilled. Reaching home she was taken with a violent chill, followed by fever, with sensations of warmth and fulness in the pelvic tissues, with sense of bearing-down pain; no signs of blood.

During September the patient experienced at irregular times, sensations of chill followed by fever, nausea, vomiting, and loss of appetite; natural nervousness increased by the thought that she was yet pregnant, notwithstanding the much medication and that the probe had been passed upon three different occasions, to encourage an outlet for the so-called retention. At night especially, she was troubled with unpleasant dreams, high temperature, chills and flightiness, indicative of mild deliria. These were attributed to excessive nervousness and hysteria. Unknown to the usual attendant, another was called in one evening during such a slight delirium, who be-

Fig. 1.—Uterus with ovum of about four weeks; a, button-hook, causing lacerations about cervix; b, probe, causing lacerations of the decidua vera at d; c, gestation sac.

lieved there was retention from pregnancy, with sepsis, and proceeded with instruments—which seemed very unclean—to encourage bringing away what was there. He seemed to stretch something (probably the cervix only), causing a slight appearance of blood but not much pain; he called but twice.

When increased pains and nervous disturbances produced by this stretching had quieted, the patient, to encourage the treatment, would lift heavy chairs, boxes and weights, but without effect. Toward the beginning of November, attendant No. 1 suggested that she be removed to the hospital as she was developing typhoid fever, as at this time, beside spasmodic pains with irregular chills and fever, she was seized with vertigo upon the least exertion, followed by loss of consciousness. Thereupon attendant No. 3 was called, who from the patient's account, suggested that there might be extrauterine pregnancy, though he had not examined her, and advised immediate removal to the hospital for chloroform examination and treatment. Instead of complying, the husband removed the patient to another hospital, where attendant No. 4 diagnosed normal pregnancy, with hysteria, accusing the patient of desiring to come there for the express purpose of having the uterus emptied. While here the marked pelvic pains and fullness were much relieved by hot fomentations to the abdomen.

¹ Meeting this patient a short time ago and hearing some compliment extended her because of her splendid physical appearance, I requested and obtained the pleasure of writing her up, hence the "years ago."

The patient left hospital No. 1 after six days. The first night at home she developed such fever and delirium that the husband removed her the next day to hospital No. 2, where attendant No. 3 was in attendance. Here chloroform narcosis established a normally situated pregnancy, ovaries enlarged and swollen; with excessive nervousness. She remained here two weeks; during the latter part of the second week she developed an inflammation of the rectum. After the second week, not improving, the patient again returned home, where attendant No. 5 was called in, who believed the case one of pregnancy with some serious complication, and called but once. Attendant No. 6, upon examination, recognized the rectal abscess. The rectal abscess broke within four days, pus and blood coming away with the frequent stools. Thanks to the rupture of the rectal abscess, attendant No. 6 found the patient much relieved during the two following days, the hope being extended to her that her trouble would soon cease. But after these two days her nervousness, fainting spells, irregular chills and fever, pelvic pain with dysuria, returned with gradual increase. Attendant No. 6 now said that there must be something there (in connection with the pregnancy) which must come away or be brought away, else she would die, but he did not wish to continue the case; he did not make a diagnosis. Thus the case had continued from September, with its various probings and treatments, with its irregular manifestations of hysteria, nausea, vomiting, loss of appetite, marked thirst, chills, fever, pelvic pain and heat with gradual exhaustion and emaciation.

Fig. 2.—Uterus with fetus of about the fourth and a half month; a, pyometro-salpinx; b, fetal membrane; c, fetus; d, left tube; e, uterine wall, normal.

About the middle of December I saw the case for the first time and diagnosed an intrauterine pregnancy (Fig. 2C) with a pyometra (Fig. 2A) extending up into the left tube (Fig. 2D) a pyometro-salpinx (Fig. 2A-D) with chronic systemic intoxication from septic absorption, infection having occurred most probably from the repeated and ineffectual attempts at the induction of abortion (Fig. 1, A B D). There was emaciation with cachectic appearance, anemic murmurs and evening temperature, with morning drop. Examination revealed an enlarged four to five months' pregnant uterus with a readily outlined bulging of its left side apparently extending up and into the tube (Fig. 2, A-D) gradually diminishing in size toward the outer third of the tube. The right side of the uterus and pelvis were normal, and not sensitive to the touch, but the left side of the uterus, continuing up to and along the tube, was very sensitive, was tumefied and gave a sensation of a purulent collection. The cervix was firm and closed. There were irregular bearing-down pains, quite strong in character, but not sufficient to cause dilatation of the os or to rupture the pyometro salpinx. Calomel was administered and a 3 per cent. carbolic douche ordered, *t. i. d.*, thinking that from the consistency of the abscess and the well-marked uterine pains the pyometro salpinx would thereby be encouraged to find exit through the cervix: if so, pregnancy might continue to term. After seven days of this treatment the pyometro salpinx broke through the cervix, pus, blood and clots appearing in greater quantities than in the case of the abscess in the rectum. Relief again followed and I hoped that pregnancy might now continue without further difficulty, therefore I did not rupture the gestation sac; there continued a slight flow of pus and mucus, but again after the third day the old complex of symp-

toms reappeared and increased, notwithstanding the decreased sensitiveness of the uterus and tube of the left side. This I attributed to the irritation between the abscess walls and the growing gestation sac (Fig. 2B-A-D) and the retention of abscess contents above, caused by the pressure of the gestation sac upon the collapsed abscess uterine walls below, thereby cutting off drainage. Therefore I decided to induce premature labor and empty the uterus.

With Dr. Barnard's assistance the patient was chloroformed. She took chloroform very unkindly and was very weak, notwithstanding hypodermic stimulating injections, so much so that we felt it would be better not to conclude the emptying of the uterus, but to rest satisfied with dilatation of the cervix and breaking down of the gestation sac, and remain ready for any emergency, should one arise. With considerable difficulty she was revived. The pains reappeared, but were now more normal in character, the contractions continued to increase in strength and rhythm, until after thirty-six hours, a four and a half months' macerated fetus was expelled without much pain, the patient having been given codein.

After a few hours the exceedingly foul-smelling secundines were expelled without assistance. Relief was so great that the patient immediately fell into a profound slumber from which she awoke with the cry of, "Where am I? Please give me something to eat," the first craving for food in several months. No drainage. Convalescence was slow, but perfectly established by April.

Had she not been in so low a state the uterus would have been emptied at once. From this distance it may seem to have been more judicious to have assumed the risk and have wholly emptied the uterus at the time. I think I would do so should I have another case under like extreme conditions. Yet that the uterus was not wholly emptied was not without its advantages, as with the return of consciousness she appreciated more and more perfectly the increasing severity of the growing uterine contractions. The pain seemed to act as a stimulant, arousing the system to react with splendid physical effect, as was so beautifully shown in the subsequent course of the case.

It reminded me very much of one of my first tracheotomies. It was an emergency case in diphtheria where I had but my pocket-case with me. Picking the unconscious child from off the bed, laying her upon the table, in cutting I noticed that no reaction ensued until I was down upon the trachea, and then only was it necessary to hold her from struggling when the tracheal rings were cut. While waiting for the tracheal tubes to come from my office (twenty-five minutes), I held the artificial rima apart with my pocket-case dressing forceps, and observed that when holding forceps still in keeping the rima open, no reaction, such as increased respiration or cough followed, but when the forceps were moved, causing pain, the little one reacted with increased physical effect, so that by the time the canula arrived the trachea was comparatively clear and the breathing much freer and more regular. She made an early recovery and is alive and well.

Among other striking features this case amply testifies to what extremes, even repeated attempts and long continued inimic intentions may be carried to induce abortion, yet successfully neutralized by the physiologic resistance of the part locally and by the system generally. Here was a case of uninterrupted intrauterine pregnancy, notwithstanding the repeated and severe attempts to induce abortion, with infection from the traumatism dating probably from the application of the button-hook, increased by the chill of the rainstorm, the repeated active probings and the various treatments. Infection gave rise to unilateral septic purulent deciduitis, metritis, salpingitis and cellulitis of the left side (Fig. 2), and what is remark-

able is, that pregnancy should have continued without interruption, the gestation sac, having escaped the intended injuries, apparently acted as a bar (Fig. 2 B) to the further extension of the inflammatory process to the other side.

Another instructive feature of this case is that the unusual and exaggerated nervousness was regarded as only hysteric in nature. It is true the patient was of a hysteric temperament, but such a spasmodically exaggerated form so long continued, characterized by intervals of normal serenity, yet with patient exhibiting irregular chills, fever, nausea, vomiting, tenderness and warm pelvic fullness during the whole time, with such a history of traumatism and intended abortion, it seems to me that such a complex of symptoms might have suggested another more active cause for this increased apparently hysteric manifestation, viz., the systemic intoxication from the local septic process. In proof of this when the rectal abscess broke, when the pyometro-salpinx emptied itself through the cervix, there followed an improvement in the physical as well as in the mental condition of the patient, but only a temporary improvement, as the irritating cause, the pyometro-salpinx, was still active. Emptying the uterus, all was changed; her long-continued dulled but exaggerated mental state immediately cleared up; locally, douching alone cleared away the retention products from the abscess and post-partum walls. Convalescence, though slow, was perfect.

Another very interesting feature of this case is that, when the uterus became emptied of fetus and secundines and pyometro-salpinx, in the collapse of the uterine walls following this emptying, the freshly denuded gestational walls came into close approximation with the septically infected and long-continued pyogenetically inclined abscess walls of the other side of the uterus, and of that tube (Fig. 2E-AD); yet no new infection occurred on the side of the freshly denuded surfaces. On the contrary, the local condition gave little more trouble than after an ordinary labor or a benign pelvic abscess, where opening alone will suffice to rapidly restore.

Similar cases of repeated attempts at the induction of abortion with failure, are reported by Dr. H. F. Vickery of Boston and Professor Fritsch of Halle. As these cases present points of interest of more than passing notice it may not be amiss to introduce here short extracts.

In the *Boston Medical and Surgical Journal* of October, 1890, p. 413, Dr. Vickery reports under the head of "A Much Enduring Fetus," as follows:

POINTS OF INTEREST.

1. Conception occurred while mother was nursing a child only 6-8 weeks old.
2. That pregnancy should persist despite so many adverse influences. In November, baby one month old; profuse menstrual flow. December, not appearing, took tansy tea, turpentine, catheter daily effort for three weeks. Toward end of January thought she had succeeded; constant metorrhagiae through February to middle of March; obliged to call her physician, who mitigated the flow by exhibiting ergot; flow continued. Then blunt wire curette for what had been regarded as retained placenta, followed by swabbing inside of womb with Churchill's tincture of iodine. It is probable that this operation did not affect more than the cervix; flow continuing douched with gallon of hot water t. i. d. for four days, still hemorrhage persisted. Patient now profoundly anemic. V. invited to see her and remove obstinate placenta. V. found fundus reaching nearly to the umbilicus—induced labor and emptied uterus—convalescence uninterrupted but slow. Fetus 5-6 months.
3. That the woman escaped sepsis or any permanent injury.

In the *Obl. für Gynekologie*, 1880, p. 197, there appears a case of Professor Fritsch reported under the head of "Ein Hartnäckiges Ei" (referred to him and reported by Dr. Stumpf, *Cent. f. Gyn.*, 1879, p. 457), as follows:

PREVIOUS HISTORY.

A primipara with rachitic pelvis was delivered (December 1877) of a breech presentation fetus, with the assistance of a blunt hook, after much difficulty. A vesico-vaginal fistula soon after developed, which was operated on by Professor Fritsch three different times; finally, in the autumn of 1879, perfect vesical function was attained.

PRESENT CASE.

In 1879 the patient was again pregnant. Consultation of a local physician with Prof. F. determined that because of: 1, rachitic pelvis; 2, danger of rupture of a so hardly won vesico-vaginal cicatrix it was suggested that abortion be induced, to which the patient responded with the request that it be done as soon as possible. Oct. 20, 1879, a sound was passed by the local physician. Considerable pain was felt when the point of the sound entered the os; a laminaria tent was then passed into the cervix and the vagina tamponed. When the tampon and tent were removed there was hemorrhage and it was supposed that the ovum had come away in the clot. The patient not being satisfied that the uterus had been emptied, fourteen days after she traveled to Professor Halle, who passed a sound into the uterine cavity and moved it about in every direction. Some blood came away, yet pregnancy continued. Jan. 14, 1890, a bougie was introduced into the uterus and left there, and abortion of a normally developed four-months' fetus resulted.

Fig. 3.—Perfect decidual cast from eight to nine weeks abortion; U, uterus (schematic). Decidual cast: a, decidua vera; a1, decidua vera cut open and reflected; b, decidua serotina; c, gestation sac; d, peritoneal cavity containing ovum; e, and f, invading probes; g, where probe e, has ruptured through decidua vera; h, fetus.

The ease with which such instrumentation may fail of producing abortion may readily be appreciated by examining Fig. 3, a perfect decidual cast of an eight to nine week pregnancy, containing the gestation sac (C) still unruptured. To induce abortion the usual method is to separate or to rupture the decidua vera (A. G.) and the fetal membrane outlining the gesta-

tionsac (C.) This is done by passing the probe (E. F.) catheter, or other instrument alongside of or through the decidua vera (A. G.) and into the *perioneal* cavity (D), or by the twisting process the probe may be carried to or about the fundus uteri, passing through the decidua vera there, but often missing the gestation sac (as in Fritsch's, Vickery's and present case). The mucoid perioneal or decidual fluid comes away, which is incorrectly regarded as the liquor amnii; some blood flows, followed by pain and other reflex signs and symptoms, but the local physiologic resistance is at times, as in the present cases, so great that it neutralizes the shock of the malignant attempt and, notwithstanding traumatism and perhaps infection, pregnancy continues uninterrupted. Hence the ease with which operators are frequently deceived into thinking their attempts at abortion successful. The uterus is repeatedly entered and actively sounded, reflex signs and symptoms arise but soon subside, yet pregnancy continues. Again, and not seldom, this will explain the unfortunately not few cases of continued and interrupted pregnancies accompanied with complications of a so-called "peculiar type" of enteric fever, peritonitis and typho-peritonitis, with their fearful morbidity and mortality, which follow in the wake of these attempts at abortion.

Again, it is not difficult to understand how these attempts at abortion may occasionally give rise to malformations or monstrosities. The end of the probe or other invading instrument is carried into the perioneal cavity. The point of the extremity may strike the gestation sac, and often does. Where destruction of the sac occurs, death of the embryo, as a rule, follows—abortion usually does; in some few cases, retention is the case. The retention may disappear through absorption or casting off by necrosis, or the retention may undergo other changes.

But in some cases the resistance of the membranes of the gestation sac neutralizes the shock of the invading stroke, or again, the invading stroke may have been an oblique one and thus have glanced off. In both cases the effect would be the same; the membranes would remain intact, perhaps, showing no trace whatever of the traumatic intent. Yet the embryo (Fig. 3 H) within the gestation sac may not be so fortunate as to escape evil consequences. Though the membranes of the sac remain unaffected the potentialities of the abortion stroke may have continued on and been expended upon the embryo, causing trauma, resulting in inflammation or death of a few cells, or of a part or of the whole of the embryo—a condition analogous in later life to the trauma often found in the abdominal cavity following blows, falls, etc., though the effect of the force has left no trace upon the abdominal walls, a part in the abdominal cavity often shows a serious lesion. The effect of inflammation or destruction of a few cells even, during the early stage of embryonic life, as the cells during this period possess the function of germinal cells, may result at a later period in a serious developmental malformation. Writing upon the subject of

the genesis of monstrosities and malformations, Ziegler says:

Malformations may be of two kinds: On the one hand, the ovum may have inherited a tendency to abnormal growth; on the other, a normal embryo may in the course of development be affected by disturbing influences from without which check its progress toward the perfectly developed form. Experience indicates that both events occur. The recurrence of hereditary malformations in the family, such as an excess or absence of fingers, toes, etc., can only be explained by the supposition that the abnormal tendency exists from the first in the embryo, having been transmitted from one or the other parent. On the other hand, the absence of one or more limbs, deficiency of the cranium, etc., are to be accounted for in a satisfactory way only by assuming that external causes of injury have affected the growing fetus. Disturbing influences acting on the otherwise normal embryo play a far more important part than heredity in the genesis of malformations. The pathologic peculiarities transmitted congenitally from parent to child manifest themselves less in anomalies of external form than in deficiency or perverted function of the tissues or in morbid predispositions. Such anomalies are to be detected only by minute anatomic examination, or they are incapable of anatomic demonstration at all. The causes of malformation in any given case can only be approximately determined or referred to this or that hypothetical injury. Monstrosities by defect are commonly malformations by arrest; they owe their existence to a local hindrance to the development of a normally constituted embryo. The earlier the injury the greater is usually its effect. The loss of a few cells in the earlier stages of growth may involve the absence of an entire limb or organ; while later on, after the general form is nearly complete, the same loss might not be noticeable at all. Malformations, in the narrowest sense of the term, originate for the most part in the first three months of fetal life.—Ziegler: *Lehrbuch der Allgem.*, etc.

There is a rapidly developing germ-embryo made up of cells whose sensibilities and function are the greater the earlier the stage of growth. At the first day the sensibility and function of the individual cells are far greater than at the thirtieth or ninetieth day. The earlier an injury occurs to these cells the greater must be its effect; a cell or a few cells impaired or destroyed in the earlier stages of development must certainly pervert and stunt the further development to that proportionate extent, even may involve the absence of an entire limb or organ; but later, as is easily conceivable, the same loss may not be noticed.—(Stahl: "Maternal Impressions."—*Amer. Jour. of Obstetrics*, Vol. xxxiii, No. 4, 1896.)

Personally I have never met with such a case of fetal malformation, due to instrumental attempts at abortion, though I remember having such a case related to me for my opinion as to its probability. A patient was confined of a seventh to eighth months' fetus. Before he had mentioned to her anything about its appearance, the parturient remarked to her physician that she feared to look at it as she was afraid that some mark might be present of the repeated attempts that had been made during the first two months to interrupt the pregnancy. To the sister the physician stated that there were marks about the head showing that violence had been used in some manner, causing deformity, especially about the eyes and forehead.

Dr. T. R. Chambers, in the "Trans. of the N. Y. Path. Society," Vol. iv, p. 117, reports a case of "a four-months' fetus, bearing the imprint of the mechanic means to cause abortion." The fetus had imprints upon the crown of its head, a result of the harsh method employed to induce abortion. She had passed a rather stiff catheter, some two days before. Though his subject title conveys the idea I would advance, his subject matter does not. His subject matter is but the natural sequence of trauma with death, followed by immediate delivery, analogous to the subsequent spontaneous delivery following a previous craniotomy in later labor.

I think the future will show, if it has not already

¹ Dr. Dorland, in his excellent "Manual of Obstetrics," uses *hydropertione* as the term for this fluid; would not *perioneal* (*περι*, around, *ὄν*, ovum) be better and more simple, therefore *perioneal* fluid and *perioneal* cavity? The analogy with pericardial, peritoneal, etc., would be more true, since function and composition of fluid and cavity is similar. *Hydropertione* (*ὑδωρ*, water, *περι*, around, and *έρω*, to go.) This term was introduced by Breschet to describe a liquid contained between the decidua vera and decidua reflexa, designed, he thought, to nourish the embryo at an early period of gestation.—(FOSTER.)

been shown, that these attempts at abortion, without necessarily affecting the gestation sac, may affect a few of the germinal cells of the embryo, resulting in their inflammation or death, without seriously affecting the life of the embryo as a whole. The life of the embryo continuing, the further development of the embryo will be stunted in so far as the area is to which these cells give development. Thus a slight destructive effect to a few developmental cells in the embryo may give rise to a serious malformation or monstrosity in the fetus.

Again, but a glance at Figs. 1 and 3 will suffice to explain why in the exceptional case menstruation may occur in the presence of an ovum (intrauterine), and continue through pregnancy; it will likewise explain the origin of a *hydromenorrhea gravidarum*, or, *hydromenorrhea decidualis*, the so-called false waters of pregnancy.

Fig. 3 shows the probe F breaking down the fibrous deciduo-uterine union, and thus more or less breaking open the uterine vessels, exposing them to the entrance of infection and of air. This might explain also the possibility of air emboli or the entrance of air into the circulation with sudden death. Fortunately this fatal expression is rare, and indicates very strongly that mere separation of the decidua and exposure of the sinuses are theoretically more prominent as the causative factor of air emboli than practically seems to be the case. Of the immense number of these cases of instrumental attempts at abortion; in operative labors, as in podalic version with extraction, difficult and rapid forceps delivery, where serious cervical and uterine lacerations are sometimes unavoidable; in ruptures of the uterus and Cesarean section, or in gynecologic and surgical operations where important vessels are exposed, it is only for a moment, but a moment is sufficient where pathologic desire seeks an opportunity; in these many cases where blood and lymph vessels are opened and exposed it is very seldom, in fact, comparatively speaking, rare, that sudden death occurs due to this cause, entrance of air into the circulation. The conclusion would seem appropriate that where in an exceptional case death does follow from this cause, some other rôle plays the more active though favoring influence than does the mere exposure of the sinuses and channels.

The treatment of this class of cases with infection and retention, whether partial or complete, should be immediate dilatation and emptying of the uterus. Hysterectomy would hardly be called in question.

IRREGULARITIES OF THE DENTAL ARCH.

Presented to the Section on Stomatology, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY EUGENE S. TALBOT, M.D., D.D.S.

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE,
CHICAGO.

Having in the last two decades given much attention to researches on the etiology of the types of faces of most nationalities, I propose to present the causes of irregularities of the dental arch in a concise, practical manner. In studying the etiology of irregularities of the dental arch, I shall discuss the merits and demerits of some of the later theories, including those as to the alleged normal dental arch. Two misleading classifications of what constitutes normal dental arches

have been advanced by able practitioners of dentistry.

"The American System of Dentistry," Vol. ii, page 1030, published in 1887, contains an article entitled "Dental and Facial Types," in which the author, after discussing temperaments, attempts to show that certain forms of dental arches (which he calls types) are characteristic of different temperaments. Thus, "the arch of the bilious temperament from cuspid to cuspid is almost flat, the lines backward from these points divulging in an almost straight line. The dome of the mouth is high and almost square. The sanguinous arch resembles a horseshoe in shape. The dome of the mouth is high and semicircular. The arch of the nervous temperament presents a strong contrast to either of the two preceding, and is sometimes spoken of as gothic, from its pointed character. From the central incisors, which often overlap for want of space, the line of the remaining teeth continues backward with a slight curve, the greatest prominence being between the cuspids and first bicuspid. The roof of the mouth partakes of the same curve and angle as the arch. The lymphatic arch is almost semicircular in its outline, and somewhat resembles the sanguinous temperament. The dome or roof of the mouth is flat and low."

In "The American Text-Book of Operative Dentistry," page 18, the author of the chapter on "The Dental Arch" remarks: "The square arch (which resembles Ivy's arch of the bilious) is found usually in persons of strong osseous organization, of Scotch or Irish descent, of Gaelic extraction. The round square (which resembles Ivy's sanguinous) is the medium arch, and is the form usually met with in ordinary well-developed, robust Americans. The round arch is the circular or horseshoe. . . . The arch is quite characteristic in some races, as the brachycephalic, South German. The round V (which resembles Ivy's nervous arch) is constricted in front or narrow, so that the incisors mark a small curve, whose apex is the center. It is the arch of beauty, and that most admired in women of the Latin races."

When the causes which produce the changes in outline and deformities are fully understood, the absurdity of the theories from the standpoint of late researches becomes apparent. Since the frontal arch can not be outlined until all the permanent teeth are in position—as nothing can act except it exists—and as these deformities are never observed in connection with the first set of teeth, in order to study the normal or deformed arch, the person must have reached the age of from 6 to 12 years. It is self-evident, then, that the influences which bring about changes in outline must exert themselves at that period and not earlier. In order, therefore, to understand the normal as well as the abnormal dental arch, the human face and jaws must be studied.

The evolution of the human face and jaws is rather complicated, since their development is the result of two forms of evolution: 1, the evolution of the face and jaws from the embryo to maturity; 2, the evolution of the face and jaws from the anthropoid ape to that of the present man. The human face is modified backward from the vertebrate type. It is an additional illustration of the degeneracy of a series of related structures for the benefit of the organism as a whole. The progress of development of the face in the vertebrates is checked in man: 1. As Minot¹ remarks, because the upright position renders it unnecessary to

¹ Human Embryology, p. 468.

bend the head as in quadrupeds. 2. Because the enormous cerebral development has rendered an enlargement of the brain cavity necessary. This has taken place by extending the cavity over the nose region as well as by enlarging the whole skull. 3. Because the development of the face is arrested at an embryonic stage; the production of a long snout being really an advance in development which does not take place in man.

The human face at birth is so near that of the monkey that if only the heads of both were exposed to view, it would be difficult to distinguish one from the other. Cope² has made the following classification of the head and face for comparative study: "The relative size of the cerebral to the facial regions; the prominence of the forehead; the prominence of the superciliary regions; the prominence of the alveolar borders; the prominence and width of the chin; the relation to width of skull; the prominence of the malar bones; the form of the nose; the relative size of the mouth and lips. At birth in the infant ape, the facial region of the skull is smaller than in the adult, the forehead is more prominent, the superciliary ridges are more prominent, the edges of the jaws are more prominent, the chin is less, while the cheek bones are more prominent, the nose is without a bridge, and has short and flat cartilages, the face is flattened, the orbits are smaller and closer together, the mouth is small and the lips are thin. In the typic infant child, as he begins to develop, the cerebral part of the skull more than in the adult predominates over the facial; the superciliary ridges are not developed; the alveolar borders are not prominent; the malar bones are not prominent; the nose is without a bridge and the cartilages are flat and generally short; the eyes are larger." In this last particular the human infant resembles the lemurs, and thus retains an embryonic tendency. In some degenerates this tendency remains unchecked, and the result is unusually large orbits. In other instances the human fetus passes through this lemurian stage to reach and even exceed the anthropoid in smallness and closeness together.

In a paper read before the Odontographic Society of Chicago and the First District Society of New York, and just published,³ entitled "Degeneracy in its Relations to Deformities of the Jaws and Irregularities of the Teeth," I showed how evolution of the face progressed from the ape to man until it presented a perpendicular line, and that recession of the jaws was still going on. In the evolution of the jaws from birth to maturity there is constant enlargement of the alveolar process brought about by the crowns of the teeth and broadening of the rami by the development of the skull, which is claimed by some writers to stamp the type of jaw. Tones⁴ has shown after repeated experiments that the inner surfaces of the fetal jaws remain the same throughout life; that the development and growth are almost entirely upon the outer plate of bone anteriorly and laterally, and that the jaw grows posteriorly for the purpose of containing the molar teeth. It is this growth that is checked by the other forms of evolution which characterize the race. It is this growth that is checked in development at some period in the evolution of the face and jaws from the fetus to maturity, the result of

degeneracy. Having explained the two forms of evolution which take place in the face and jaws, it is fitting at this point to return to the discussion of the type of jaws.

When man was more of an animal than he is today, in other words, when his jaws protruded beyond the perpendicular line, it was possible in brachycephalic and dolichocephalic skulls, to show these distinct forms of dental arches, as represented by Ivy. This, however, could not be relied on, since, as I have shown,⁵ it is possible in one family, to say nothing of nationalities, to change from a complete dolichocephalic head to a most perfect brachycephalic, and vice versa, in four generations. Granting that one parent possessed a brachycephalic and the other a dolichocephalic head, what would be the shape of the jaws in the two intermediate generations? These facts are antagonistic to this theory, since the temperaments change more readily, and since the jaws are affected particularly by constitutional and local effects. Again, I have also found that the tendency of all nationalities is toward the mesocephalic type of head, and is strongly illustrated in the negro race, which is supposed to be a long-headed or dolichocephalic race. In an examination of over 3000 negroes in Chicago, I found only six that were long-headed, and four of these bordered upon the extreme mesocephalic type.

It is easy to see why temperament has very little to do with the shape of the dental arch. Two individuals are married, one a nervous and the other a lymphatic, bilious or sanguinous temperament, all having different jaws, the offspring inherits the jaws of one, the teeth of the other, and the temperament of the child is changed. The local condition is such that the shape of the jaw may change the character of the arch entirely. One child may possess a broad dental arch, but very short, another a very narrow and long dental arch. Hence, classifying the dental arch and vault by temperament is wholly out of the question. Likewise the theory of placing fixed types of jaws with different nationalities is utterly impossible, since all forms of dental arches are observed in each nationality. Some of the primitive races, like the Negro, Chinese, the Latin races, etc., retain the excessive jaws, while the Anglo-Saxon, Scandinavian and Gaelic races in most cases have passed far within the perpendicular line. It is possible for the arrested jaw to be found among the Negro, Chinese and Latin races, and large protruding jaws among the Anglo-Saxon, Scandinavian and Gaelic races. These would be atavistic on the one hand and degenerate on the other.

It remains now to explain how irregularities of the arch are produced, and also why, in the present people (bilious, lymphatic and sanguinary), dental arches can not be fixed and confined to distinct nationalities. It is not that the evolution of the face has assumed the perpendicular line that it becomes of interest to practitioners of dentistry. The teeth do not change (in size) to correspond to the size of the jaws, therefore, at this period, the jaws are as small as they can possibly be to contain them normally. Some years ago,⁶ I divided irregularities of the dental arch into constitutional and local: *Constitutional*, because arrest and excessive development of the maxillary bones may be caused by inherited predisposition, but more frequently by constitutional diseases, at any period

⁶ Dental Cosmos, October, 1889.

between birth and the sixth year, resulting in an unstable nervous system. These excessive and arrested jaws may become inherited in succeeding generations. I mention the sixth year because these deformities are never observed in connection with the temporary set of teeth, but invariably after that period. Owing to this unstable condition of the jaws, there may be a lateral arrest of development, with a protrusion of the jaws beyond the perpendicular line. In such cases there may be V and saddle arches, and the face will assume the hatchet shape. *Local*, because irregularities of the teeth may be the result of undue influence of adjoining or occluding teeth. A local condition which might easily be taken for a constitutional cause is when the first permanent molars, from any cause, may move forward, thus diminishing the space required for the anterior teeth.

In the constitutional variety of irregularities of the teeth, arrest of development of the jaws invariably takes place. The jaws being too small to contain all the teeth, nature is trying to overcome this difficulty by dropping the third molars and the lateral incisors, hence almost invariably arrest of development of the jaws exists when these teeth are missing. It not infrequently happens that although the third molars may be missing, there is not sufficient room for the anterior teeth to develop normally. Given a jaw too small for the long diameter of the teeth, a break must take place in the dental arch. After eight years of constant study, watching the development of jaw deformities and making artificially every movement of the teeth which produces them, I showed, in a series of papers,⁷ that irregularities of the teeth were merely a mechanic arrangement, depending entirely upon the jaw on the one hand, and the teeth on the other, and that mouth-breathing, thumb-sucking and other external conditions (which up to that time were supposed to be the cause), had nothing to do with them.

Two typic breaks take place, each depending entirely upon the relation of the cuspid tooth to the other teeth. If the cuspid comes into position after the bicuspid have erupted, the break is in the anterior part of the mouth, producing the V variety, which is atavistic, resembling the reptilian type. If the cuspid erupts before the bicuspids, the break is at the sides, forming the saddle arch, also atavistic, resembling the carnivorian type. Modifications of these types are the result of local arrangement of the teeth as they erupt. One of the most marked examples of this is where the temporary molars are retained too long in the jaw, the roots retaining the crowns of the bicuspids in a smaller circle. When the temporary teeth are removed, the crowns of the bicuspids are deflected inward from want of room by the adjoining teeth. The cause and manner of formation of the local variety of irregularities have been described so often in my papers and books that it seems unnecessary to enter into their discussion at this time.

It will be seen therefore that a race or individual, regardless of temperament, whose face and jaw, in the order of evolution, has become arrested at any point within the perpendicular line—depending upon local and mechanic construction of the dental arch—can not possess fixed dental types of jaws and teeth.

A METHOD OF HANDLING ALVEOLAR PYORRHEA.

Presented to the Section on Stomatology at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY GEO. T. CARPENTER, M.D., D.D.S.

CHICAGO.

In presenting this paper before this Section, I do so with a feeling that the practical side should not be lost sight of while we are eagerly searching out the scientific. Much has been written on the subject of pyorrhea alveolaris and there is a great difference of opinion still existing as to the etiology, pathology, diagnosis and treatment of this disease. It is not my purpose in this paper to discuss the various points above mentioned, but to give a brief outline of a method of handling these cases which has given me the most satisfactory results. It has been my experience that different cases of pyorrhea differ in their treatment. One case may yield readily to a certain treatment, while another may be very persistent in its pathologic behavior. But thoroughness in diagnosis and treatment is the key to success. In diagnosing any case, get a history of it and decide on the predisposing cause, or cause outside the pocket, which is generally from local irritation caused by wooden toothpicks, ligature, wedging of teeth, or ill-fitting plates or crowns, accompanied with neglect of the mouth. These, or other causes should be removed, and any constitutional predisposition should be corrected, and then we should secure the hearty co-operation of the patient. The disease once established is self-sustaining and it is within the pocket that we must look for, find, and remove the exciting cause, which may be serumal deposits, pus-secreting membrane, foreign substances, or diseased or necrosed margins of process. To make a careful and thorough examination of the pockets I secure dryness with bibulous paper, protect the parts with a napkin, and coat the surrounding gum with cosmolin to protect the parts outside the pocket from the action of medicines. Now dry the pocket and pack with cotton slightly moistened with a 4 to 8 per cent. aqueous solution of cocain. After allowing this to remain several minutes, carefully remove the cotton. The pocket will be found to remain open so that an examination can be made with a mouth mirror. Deposits, if present, can be located before instruments are used for their removal. I operate on but one tooth at a time, or on the interproximal space between two teeth, doing all that I intend to do in that immediate locality before directing my attention to other teeth. All loose teeth having lost two-thirds or more of their natural support are extracted. The best instruments to use in the pockets are spoon-shaped excavators with the shanks bent so as to reach every part of the root, or pocket. They must be kept sharp so that deposits can be easily removed, and the root curretted. The soft parts and margin of process can also be curetted if necessary. The pocket should be cleansed with equal parts of peroxid of hydrogen and pasteurin, or 3 per cent. pyrozone and borolyptol, using a flat-pointed syringe, and pass to the bottom of the pocket. This syringe is designed especially to reach pyorrhea pockets, and can be used as successfully on posterior teeth as in the front part of the mouth, and fluids do not escape beside the point until the pocket is distended and all parts are reached. This will not only antiseptically cleanse, but will also

mechanically carry out all free and loosened particles. The gums are now wiped dry and painted with tincture of iodine, which should be repeated about twice a week.¹ The tooth, if loose, is supported by bands, or ligatures, and if moved by occlusion I grind the tooth, or its antagonist, sufficiently to prevent all movement, so as to procure rest for the affected parts. All subsequent treatment of the pocket should be made by the use of a thinly shaved hardwood toothpick, which can be moistened in the antiseptic and bent so as to reach any location. This should be passed into the pocket as deep as possible without injury to the tissue, or causing pain or hemorrhage, and repeat the application once or twice a week, as long as the toothpick can gain entrance to the pocket. I find that it is seldom, if ever, necessary to make incisions through the gums into the pockets and I but seldom resort to the use of dilute or stronger acids as an aid in softening or removing deposits, or to establish resolution. Antiseptic and prophylactic conditions should be established and followed during treatment, and indefinitely continued throughout life. I recommend a thorough rinsing of the mouth and the use of an antiseptic after each meal. I also recommend a medium stiff toothbrush to be carefully used once in twenty-four hours, and that at night before retiring. This time once established will not be substituted for other hours in the day. The brush will have time to dry, and the elasticity of bristles be restored, which will do the best work at the most needed time. A good dentifrice with precipitated chalk as a base should be used on the brush, after which 1 dram of pasteurin or borolyptol should be taken into the mouth and retained for from three to five minutes, at the same time moving the cheeks and lips so as to force it between the teeth and reach all parts of the mouth, then expectorate and retire without rinsing the mouth with water. The time spent in the successful treatment of this disease depends on constitutional condition of the patient and the extent of the disease, or the thoroughness in which the first operation is performed. The recurrence of the disease comes from a failure to remove the predisposing causes. The reproduction of gum tissue² in all interproximal spaces is essential to prevent the lodgment of food or injudicious use of the toothpick. I believe that a thorough removal of the cause, with antiseptic treatment and stimulation of the gum tissue will cure the most persistent case of alveolar pyorrhea.

THE MECHANISM OF MAN—ITS EGO AND COSMOS.

Presented to the Section on Physiology and Dietetics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY SAMUEL KNOX CRAWFORD, M.D., LL.D.

Late Surgeon Fiftieth Ohio Infantry; Medical Director Hospital Steamers; Member of Operating Board Twenty-Third Army Corps; Chief Operator Second Division and Surgeon in Charge of Field Hospital.
CHICAGO, ILL.

None but the creative power from which all things sprang can aspire to the construction of something out of nothing, or the reconstruction of an entity into nothing. Chemistry attempts to describe all mate-

rial substances, to tell of their ultimate particles, and formulate the laws which govern their combinations and decompositions, but does not assume to create or annihilate the molecule with which it deals or the atom which it fondles. This is in obedience to the inevitable and immutable law of the indestructibility of matter and force. Matter is tangible; force is intangible. Matter is found in states; force is responsible for the state. Matter is also found in kingdoms; force is again ruling it. The one is made to grow from within by the complicated power of nutrition; the other to increase from without by the simpler but tardier function of accretion.

The organic and inorganic comprise everything that occupies space. Animals and vegetables are the organic, and all else is inorganic. Vegetables feed upon the inorganic, and animals are fed upon the vegetables; thus the vegetable becomes the connecting link between the animal and inorganic kingdoms. Animals also feed upon each other and thus become omnivorous.

Animals and vegetables have many characteristics in common, from the standpoint of nutrition. The vegetable takes the mineral from the earth and sea and sky and elaborates it into an organic compound, and from this the animal is fed and his body reconstructed. This is accomplished by force, of which we understand but the phenomena of its work. The force within the animal enables it to convert compounds prepared by the vegetable into tissue of its own and decompose others into their constituent elements, from which it forms new combinations for its own peculiar purposes. Thus sugars and starches are formed in the vegetable, of carbon, oxygen and hydrogen, to be decomposed into hydrocarbons and carbohydrates in the animal and formed into fat.

Chemic combinations and decompositions are accomplished by force within the body as without. This is but a particular form of the general force to which all matter is subservient, but of which animals and vegetables have the employment in the performance of their functions, and must not be confounded with that other and higher form of the same force which we call vital force. Hence it follows from this that the less decomposition and recombination required to transform vegetable products into pabulum for the animal to assimilate, and the less assimilative force to be employed the greater the conservation of force within the body will be conducted. The hydrocarbons as well as the carbohydrates are heat-producing foods and serve the animal economy in the capacity of fuel. It follows that, to accomplish the final act of combustion and the evolution of heat, the greater economy is, in pabulizing, for the animal, to employ those articles that require the least amount of chemic action; and perforce assimilation demands the minimum amount of vital effort.

This is all on the principle that seasoned wood is more economic fuel than that taken direct from the growing tree. As animal bodies radiate heat from within their fabrics, as do other bodies, in the general equalization of this form of force, it follows that in a climate whose temperature is zero, a much larger amount of heat-producing food will have been required to sustain a given temperature within than in one whose thermal conditions range high toward the third-figure standard. This is a fact attested by common observation. Nature has so managed her affairs in the animal that the redundancies not

¹ Dr. Talbot: Pyorrhea Alveolaris, International Dental Journal, April 1896.
² Reproduction of Gum Tissue: Dental Review, Nov. 1897.

required to sustain temperature may be stored away in odd places about the fabric as so much surplus fuel in stock, and *this is fat*. As a factor in the cosmos, fat plays a conspicuously important part, for good in due proportions and for evil in disproportions.

But the organic kingdom abounds in another class of compounds embracing an additional component element. Nitrogen is the representative of a class of compounds that enter into all the contractile and protective tissues, as carbon is of the heat-evolving principles. Nitrogen, then, may be said to be to the muscular and fibrous system what carbon is to the combustion of the body. Hence the nitrogenous and carbonaceous principles or the nitrogenized and non-nitrogenized organic compounds. Carbon, hydrogen, oxygen and nitrogen are the cardinal elements of the animal economy and for the purposes of this paper the others may largely be eliminated from consideration. Muscular action and physical endurance, then, depend largely upon a due amount of nitrogenous matter in the pabulum from which repairs are to come. In like manner, when resistance to low temperature is required, carbon must have been supplied in amount equal to the waste to be endured from the standpoint of fuel, to contend with the radiation incident to environs. If more food be taken than the economy requires for consumption in molecular action and fuel, the surplus must be stored somewhere about the fabric or be otherwise disposed of, and hence redundancies become matters of the gravest importance, and the overflow becomes a balance of power for health or disease. Overflow deposits are typic as sources of miasms and infections, and hence the more nearly the supply can be made to conform to demand, the more certainly will safety ensue.

The mechanism of man may be said to consist of the spiritual and physical bodies, the one within the other, the one atomic, which is a form of force that, like other forms of intangibles or imponderables, can only be studied by its phenomena. The cosmos may properly embrace the entire mechanism, and the ego, consisting as it does of the spiritual man or soul, is the controlling factor of it all. As the play of the conscious self upon the whole mechanism is the play of the atomic upon the molecular structure or tangible body, it becomes a matter of great concern as to the quality of the matter or molecules entering into the composition of the parts whose functionation leads to the accomplishment of acts desired.

The disposal of surpluses and effete matter eventuates from the various forms of the general force obtaining in the fabric, and therefore, there must be a system of sewage; hence the organs of excretion obtain. If in any instance the work to be accomplished by these emunctories be too onerous for their capacity, it becomes a matter of endurance and a question of time as to impairment, and hence vitiated function. In this age of serious thought and painstaking investigation, every physician will acknowledge and every surgeon accord that diet is of the first importance in the management of the various ailments they are called upon to combat. The hygienist may employ and the sanitarian adopt the most efficient measures at their disposal in the practice of their art, and yet none so good and so masterly effective as that of dietetics. All this is subservient to the inexorable law of waste and repair of life, and the exchanges must, under the various vicissitudes of life, be provided for in proportion to the requirements from function and environment, or the penalties paid.

If an immature man be placed in a climate of high temperature, where moisture abounds in the heated atmosphere; if he be clothed in raiment whose texture poorly conducts the heat from his body at best, fed upon a diet consisting largely of carbohydrates, and required to perform severe and prolonged muscular functions, the balances of waste and repair must become embarrassed and development impeded. The systemic sewerage must of necessity become deficient, and his body a shining mark for infectional miasms. The young soldier in the field in time of war, habited in regulation clothing, fed upon the ration of tradition, fat bacon, hardtack and beans, in a climate of moist atmosphere and scorching sun, with a temperature hovering about the three-figure record in the shade, and required to do but the minimum amount of military duty incident to active campaigning, must soon become an object of disease from head to foot. If he survives the dangers of infection from the numerous foci that menace large armies and unsanitary conditions, generally he will have laid the foundations well and securely for a life of fatty ills too numerous for the vocabulary of most writers to describe. War is a cruelty and defies refinement, but as a necessity it appeals to the impulses of humanitarians and scientists to avoid the cruelties of vicious diet and the filth that betokens culture media.

Science of today does not recommend fat bacon and half-cooked beans as articles of diet from a sanitary standpoint, nor does the spirit of humanity suggest the ordinary army ration of the past as a suitable food for the brave soldier who voluntarily takes his life in his own hands in defense of his country and its honor, and in behalf of human interests and liberties under the tropics. The spirit of the age and the dictates of Christian sentiment deny that an American volunteer soldier becomes a machine at the moment of muster, and thereafter as such, is not entitled to the best sanitation that science may suggest, not incompatible with the exigencies of war. The article of primary importance in all diet lists is pure water, and the purest and best of that is distilled water. The purest ice is the artificial, which is made of distilled water.

A division of soldiers should contain four brigades; each brigade should be composed of four regiments, and no regiment should be allowed to fall far below a thousand men and officers. Every division in the field should have its field-hospital equipped in every regard with up-to-date appliances and conveniences, which would include an abundance of pure water and ice. With these articles as a base for the equipment, all else would be an easy matter of attainment. A division hospital should never be more than a half-hour's march from the remotest regiment of its composition, and if equipped with a good artificial ice machine could be the fountain at all times at which the canteen may be filled with the purest and coolest water for all. Thus armed, an army of invasion would be invincible, even under the equator, not only to a wily human foe, but its surgeons could grapple even-handed with foes of the infective type, which are far more to be dreaded.

The writer feels impelled to press this question in the face of existing conditions, as he knows whereof he speaks, from an experience of years in the field beneath a southern sun, and amidst swamps and in the thickest of miasms. A well-selected diet of articles suited to season and climate and service, whatever

that may be, is the most economic measure that can be adopted in the management of large bodies of men, whether it be in civil or military life, and whether it be viewed from the life-point of the present, the health-point of the months and years to come, or be considered from a commercial point of view.

As a business man, I would be glad of a contract with my government to furnish any division of any corps now organizing for offensive warfare in southern climes, with the purest and best of water and ice throughout the service of the command, for an amount of money equal to the pensions falling due within one year, as a result of the ravages of typhoid fever and other infectious diseases of any other command of equal strength *not* so provided for and under like conditions of service. And as a further factor of the contract I would be glad of the opportunity of accepting the present ration of the same command and furnishing another infinitely more suitable for, and more acceptable to the rank and file of the command, receiving the pensions due in two years to the crippled survivors and widows and orphans of deceased soldiers from sunstroke, rheumatoids and diseases of the brain and spinal cord, from an equal number of men not so dieted, but doing service under like conditions, as compensation for my trouble, and so confident do I feel of this that I would expect to grow immensely rich off the proceeds.

But far above the dollar stands the moral of the equation, and when generations yet unborn are taken as the representative of x , the problem becomes a serious one and the mechanism of the future man with his ego and cosmos bids us move altogether in his interests. Let the door of yesterday be closed and tomorrow's door be opened.

CARDIATION.

Presented to the Section on Physiology and Dietetics, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1896.

BY EPHRAIM CUTTER, LL.D. M.D.,

HARV. 1856, UNIV. PA., 1857.

NEW YORK CITY.

Cerebration is a general term for the functions of the cerebrum and cerebellum. Manipulation means the functions of hands, and the writer thinks that it would be well if cardiation and its fellow, cardiate, were commonly used.

The heart is an autonomy like the brain, eye, ear, epithelium, etc. Indeed, some concede autonomy to every cell in the human body. Hence it is modest to claim autonomy for the heart on general principles for the following reasons: The heart has nerves enough of its own to run it. Some three hundred years ago a Dutch anatomist executed a life-size copper engraving of the cardiac ganglionic nerve centers. The heart was covered with white ganglia about half an inch in diameter, connected with radiating nerve-fibers, like streets or railways between cities. While a medical student, I killed a fresh-water snapper turtle of about thirty pounds weight. The heart, entirely removed, beat regularly for more than twelve hours. If this is not autonomy, what is? How much more can a live heart undisturbed *in situ naturali* act of itself?

Some years ago, at Hartford, Conn., was a murderer who was to be hanged. He tried suicide, as manifested by curious respiratory symptoms and oppressed heart action. He was treated and executed a few days

after said perplexing symptoms appeared. The autopsy revealed a small, healed narrow scar, one-half inch long, just below the left nipple. In the heart was a blade of a pocket knife three to four inches long, completely buried! Happening to be there I saw both heart and blade. The history seemed incredible, but the high character of the medical gentlemen, and the exhibit are beyond cavil. Here indeed was autonomy allied to that of the above turtle's heart.

The heart not an autonomy? How then does it bent all our lives long, whether we are awake or asleep, conscious or unconscious, active or inactive? Oliver Wendell Holmes taught us to observe the live hearts of land snails in motion, in formation and *in situ naturali*, through the transparent shell of the embryo. It is a marvel of microscopy! I have seen anencephalous babes born at term where the development was perfect, save the entire absence of the cerebrum and of the bones of the cranium above the frontal arches and the ears. If the head is absolutely needful to the heart, these monsters could not be. And yet their hearts and bodies are apparently perfect. Thus we have another item of evidence to prove the heart's autonomy.

If we run on a level ground, ascend heights, lift heavy weights or do anything that requires a greater expenditure of strength, then the heart beats harder and faster. What better reason for this than that the heart nerve-centers know they must supply more force to meet these new demands, or else the united autonomies we call the "body systemic" are imperiled if not killed. The heart has a governor in its nerve ganglia, like a steam engine, but it is a more perfect governor than any other. How often four to twenty times more work is put on the heart suddenly in running up stairs! How long our hearts stand strains which in like proportions would smash the best Corliss steam engine! How quickly the heart ganglions respond! How soon they seem to know when danger comes in overwork! How hard they try to avert it by palpitation, pain, tumultuous action, pounding impulses against the ribs so as to break them (Old Author). The cases were probably old syphilitics with fragile bones.

Sometimes the heart substance ruptures from its own violence specially in psychologic distress, as in the crucifixion of Jesus Christ. The heart is a psychic center of nerve emotions, feelings, passions. In 957 allusions found in the Bible, the heart is referred to mostly as an autonomy in nearly all and sometimes in the strongest language. On the other hand, the Bible has less than 500 allusions to the head as an autonomy. One reference may suffice as evidence—"The fool hath said in his heart there is no God!" It seems he was not such a fool as to say it in his head!

We love, we hate, covet, cherish (even murder), yearn, are happy or sorry, are strong and weak in our hearts far more than our heads. The Bible says our "hearts are deceitful above all things and desperately wicked." Who can know it? The Bible never speaks thus of the head. It calls the heart the "temple of the living God," but the head never has such words said of it.

Every physician knows that the heart will live and work after the head is practically dead. The sympathetic nerves do not wholly control the heart. They could not have had anything to do when the aforesaid turtle's heart beat twelve hours after removal from the

body. The head may drive the heart as the jockey does a horse but the horse will drive itself as an autonomy. I once drove my horse, Billy Pool, off 20 miles in a new direction. Returning I threw the reins over the dasher and the horse drove himself all the way back, turning out for teams both coming and going, and clearing corners just as well as if I drove him. So may the heart drive itself, independent of the head. The heart suffers when other autonomies, the head, liver, kidneys, skin, etc., are out of order and use up so much *dynamis* (vital force) as to steal from the heart that knows no rest.

I think that three-quarters of heart troubles in women come from uterine lesions using up the *dynamis*. This may be over-estimated, but there is so much of this causal relation that no specialist of heart disease can afford to overlook uterine diseases. Note how our vernacular treats the heart as an autonomy. What does the expression "he has no heart" mean but that the heart's compassions are so stifled as not to yearn? But how can this be if the heart is not an independent organ?

We say "heartly food," meaning that such aliment strengthens or dynamizes the heart. Were there no autonomy this would mean but little.

CLINICAL LESSONS TAUGHT BY CARDIATION.

Lessen heart work and then Nature will cure by having dynamis enough to do its work with. It is wonderful how Nature cures this mighty engine while it is running and working. Man made engines stop running and go into the repair shop. "God, in whom we live and move and are," through His laws, i.e. Nature, repairs the unceasingly beating sick heart, a task that is impossible to man who has much to do, as he can destroy if he can not create. In other words rest the heart in and between its beats, by position, by keeping still, by "laying low," figuratively and literally, by freeing the body from all compression and tight environments, by lightening work, by removing all causes of psychical, mental, intellectual, sensual (in its best and worst meaning) and of physical excitement, by lessening the friction of the more than 100,000 miles of capillaries, in an adult male, *a*, making the blood or normal dilution with water, *b*, removing the adhesiveness of the red- and white-blood corpuscles, the massiveness and abundance of the fibrin filaments, the amorphous and crystalline blood gravels or crystallized bodies, such as oxalate of lime, cystine, uric acid and its salts, triple phosphates, cholesterin, etc.; removing thrombi and emboli of fibrin, gravels, fat, leucocytes, cryptogams, in fact, making the blood stream normal by proper feeding and medicines. In this way a heart that has grown large from its overwork will reduce down to normality, and valvular lesions will be restored to health. I have seen this done. If the heart is fattily degenerated, the diseased muscular fibers will be replaced by normal fibers, and if time enough is had even the stony deposits are removed. Nature, not medicine, does these things when chances are given by means of rest and plenty of dynamis being given.

SOCIETY PROCEEDINGS.

San Francisco County Medical Society.

December Meeting.

Dr. KASPAR PISCHEL presented and described a case of

FOREIGN BODY PENETRATING THE EYEBALL.

The foreign body was a chip of iron, and was removed by means of a Habb's magnet which he had made in San Francisco some months ago. The chip of iron entered the eye November 30, at once causing pain and inflammation. This was treated for some days by a general practitioner, the pain subsiding to a great extent, but it was not entirely relieved, and the patient was sent to Dr. Fischel December 6. When seen there was dilatation of the pupil of the right eye, some pain and tenderness, and vision of $\frac{5}{15}$. The wound of entrance could be seen and also a brownish stain in the lens, with an opacity in the posterior portion of the lens, which was cupped. The foreign body could not be seen, and its actual presence could not be detected. The eye was cocaineized and approached near to the big magnet, but successive trials by making and breaking the circuit in the magnet did not elicit any pain nor produce any indication of the presence of the particle. The next day the trial was repeated, but on this occasion the eye was not cocaineized. Making and breaking the circuit at times caused pain and at others did not. After a number of attempts the iris was seen to bulge when the current was thrown on the magnet, and finally it was drawn to the cornea. An incision was then made in the cornea and a small magnet introduced into the wound thus made; it failed, however, to attract the minute iron chip and the tip of the large magnet was introduced. At the first trial with the tip of the large magnet the particle was drawn out of the eye. It was found to weigh .00068 gramme. Dr. Fischel called attention to the difficulty of deciding whether there is or is not a foreign body present. In this case the symptom of pain on closing the circuit and making the large mass of iron magnetic, was not present; it has been claimed that when the magnet is approached to an eye which contains a particle of iron or steel pain is always a symptom. This is now shown to be not always the case. The question might be raised, "if there be a foreign body in the eye and there is no inflammatory trouble, why not leave it alone?" The use of the large magnet does not introduce any danger, and we know that there is always possibility of sympathetic ophthalmia when a foreign body is allowed to remain in the eye.

PHILIP MILLS JONES said: The feature of particular interest in this case is the fact that such an exceedingly small particle of iron could be drawn from such a distance, for it must have been lodged behind the lens. In the testing of the magnet which Dr. Fischel used, and which I had the pleasure of designing for him, I found that the action on such very minute particles was very small, and I should not have thought that the magnet would attract a piece of this size at the distance which it must have been. This case goes to show that the big magnets are even more satisfactory than had been supposed. The absence of inflammation may doubtless be explained by the fact that the chip of iron, when struck off by the blow of a hammer, was probably heated to a high temperature. We see such particles flying as sparks when iron is struck by a hammer in the dark. The heating would quite effectually sterilize the chip.

Dr. W. F. SOUTHARD said that he had intended to call attention to the point made by Dr. Jones, as to the sterility of these chips of iron. He had seen a great many of these cases of iron in the eyeball, when connected with the Massachusetts General Eye and Ear Infirmary. Rarely in a case of iron penetrating the ball, when it was in the shape of a chip struck off by a hammer, was there any inflammatory trouble following the injury.

Dr. PHILIP KING BROWN reported to the meeting

A CASE OF ACETANILID POISONING.

The case was of unusual interest for the reason that it had been so carefully studied both before and after death. The patient was a male, 37 years of age. He had been for some years rather constipated, with frequent headaches as a result. About January 22 he called in his lodge doctor, who left a prescription calling for 60 grains of acetanilid in 10 grain powders, with instructions that one powder was to be taken, and if that did not give relief another could be taken at the end of an hour. The man took five of the powders in quick succession, but without relieving the headache. He then became unconscious, cyanotic, vomited, and the family sent for Dr. Kahn, not however, telling him anything of the visit of the lodge doctor, nor of the taking of the acetanilid; indeed, the fact that he had poisoned himself with this drug did not appear till just before his death. For thirty-six hours he remained at home, was delirious, cyanotic, jaundiced, and seemed to complain of pain in the left side of his head and left umbilic region. There was also vomiting, with occasional chills. When removed to the hospital he was carefully examined, but no positive diagnosis could be made. He was then delirious, had chills, jaundice, almost continuous vomiting, with a temperature of 100.2 degrees, pulse 78, and shallow respirations. Cyanosis was marked, but examination of the heart failed to reveal anything. There was considerable cough, with expectoration of thick mucus. The abdomen was flat, but the viscera appeared to be normal. There was no hemorrhage of the mucous membrane. The urine was at first clear, but later became deep red in color, and about two days before death was entirely suppressed. It was alkaline, s. g. 1.016, coagulated on boiling, and contained large numbers of cysts, yellow and brown in color. The thirst, vomiting and cough with expectoration were almost continuous up to the time of death, which occurred on the sixth day after entering the hospital. For the first day he was given milk, and one-sixtieth grain of strychnin hypodermically; but as he vomited all the milk at once, and as the circulation was so poor that the strychnin was not absorbed by the skin, he was subsequently fed by the rectum, and the strychnia was also given in the same manner. The vomit was a thick green mucus. He was perfectly unconscious all the time. The reflexes were at first exaggerated, but later were lowered. The temperature dropped, becoming subnormal and reaching 75.5 degrees just before death. The circulation was at all times very poor, so much so as to prevent any attempt at medication through the skin. After the fourth day blood appeared in the stools. Oxygen was not used. Blood examination made shortly before death showed a very marked destructive process going on in the blood corpuscles, together with evidences of attempts at reparation. The nucleated elements were largely in excess. The blood was examined from time to time throughout the period he was in the hospital, and the destruction of blood-cells was seen to be progressive. Some of the clinical features noted were as follows: There was no anesthesia, and for nine days after taking 50 grains of acetanilid there was marked hyperesthesia; the motor and sensory functions were all right; the arterial pressure was low throughout the time of illness; the respirations were shallow and slowly increased, reaching about thirty six just before death; the temperature was subnormal; the alkalinity of the blood was reduced 80 per cent. The colored matter in the urine was found to be iron-free hematin, on spectroscopic examination. The following conditions were found on autopsy: In the abdomen, the liver and stomach were normal; the spleen was slightly enlarged; the gall-bladder was found filled with dark, sticky, green bile; the kidneys were enlarged and showed a condition of nephritis which seemed to be recent; the heart showed fatty degeneration; the valves were all thickened, though competent; there was a large clot in the right auricle, which was probably antemortem; the lungs showed evidence of previous damage and a catarrhal condition; frothy, bloody mucus could be squeezed out of a cut section; the intestines were the seat of a chronic catarrhal inflammation and were covered with a thick green slime.

Dr. J. HENRY BARBAT said the death is probably only one of a number that have occurred in this city, caused by taking the so-called headache powders. The amount of harm done by these remedies can not be calculated. He had repeatedly seen marked cyanosis follow the use of 10 grains of acetanilid, and while the "acetanilid compound" was somewhat better, he considered it did not contain enough caffeine to counteract the depressant effect of the acetanilid. He usually gave a little digitalis also, when making use of acetanilid. In one case where he had dusted a very small amount of acetanilid powder on the surface of the gut in a child, marked cyanosis followed and persisted for some days.

Dr. M. KROTOSZYNER strenuously objected to the manner in which physicians were making use of the coal-tar products, both those in which the formula was known and those in which it was not known. He also called attention to the fact that many physicians were using a proprietary preparation called "antikamnia," said to be composed largely of acetanilid, but of which the formula was not known. He did not consider it at all ethic for physicians to use and prescribe this remedy, as it is a secret preparation, and because it is sold so commonly to the general public as a headache cure. He considered that acetanilid should be used in all cases with the utmost care, and that five to six grains was a good sized dose.

Dr. H. D. ROBERTSON had seen a number of fatal cases of poisoning from the use of the coal-tar products, and he gave a résumé of the history of these drugs for the past fifteen or twenty years. The more recent of these productions did not seem to be so dangerous as the older ones, acetanilid, antipyrin, etc. It was a question in his mind, whether the prostration was due to a direct action or to the destruction of the blood elements. He called attention to the marked anemia following the use of trional for long periods, and suggested that the destruction of the blood corpuscles would account for the anemic condition.

Dr. E. E. KELLEY said that he was inclined to think that the powerfully depressing action of acetanilid might be caused by the poisoned condition of the blood. Dr. Brown had showed that the heart's action remained practically normal and also that the blood was profoundly affected. Could not the depressing effect and the later effect on the heart, be due to this primary action on the blood? He also suggested that the complete suppression of urine so long before death would seem to show a previous disease of the kidneys, which may have affected the action of the acetanilid and have had something to do with the cause of death.

Dr. HUNKIN said that the extent to which these headache remedies were being used was most distressing. He had recently been called to see two girls who were feeling very much upset, but could not account for the trouble. They were markedly cyanotic, languid and listless, but complained of no pain. He found that the entire family was given to using large quantities of a remedy which they all took at the slightest provocation, and for almost anything from constipation to backache. They were evidently suffering from coal-tar poisoning.

Dr. HAROLD BRUN said that the question had frequently presented itself to him, Are the coal-tar products, acetanilid, etc., heart depressants or not? He thought they were not, but that, as had been suggested, they owed their depressing action to the effect which they had almost immediately upon the blood.

Dr. SOUTHARD called attention to the personal equation, which seemed to have missed the attention of the previous speakers. In his own case two or three grains of acetanilid would have a maximum effect, and anything more than that was quite depressing.

Dr. E. G. FRISBIE also mentioned the personal equation, stating that he had frequently noticed that some persons could take very large doses of these drugs, while very small doses would have unpleasant effects with other patients.

Dr. BROWN, in closing the discussion, said that there was no doubt of the actual depressing action of these drugs. In the case reported, the administration of strychnia in large doses was all that kept the heart's action up. The drug evidently had a depressant action on the heart muscle direct. He said that susceptibility was a noted characteristic of these drugs, and was most marked in the case of acetanilid. He considered three grains the maximum dose, and that anything more than this amount should be given with great caution. In answer to a question, he said that the bone marrow was not examined in the case reported, but the brain was very carefully examined and showed nothing pathologic. The jaundice was present from the outset, and was progressive. There were no hyaloid nor fine grained casts, and the appearance of the kidneys on postmortem examination showed that the inflammation of those organs was not of long standing. The causes of death were the destruction of the blood corpuscles; the blocked-up kidneys, causing suppression of urine; the heart failure and the persistent vomiting. Starvation played a good part in causing death, and had it been possible to keep the patient nourished he would perhaps have recovered.

Dr. THORNE reported three cases of general peritonitis following pelvic disease, in which the patients were in extremely bad condition when operated upon. He said that they called attention to the fact that operation should be undertaken in many cases when there was apparently no hope whatever of recovery. The result was sometimes marvelous. In the

cases reported the temperature ranged from 103 to 106 degrees, there were chills, great pain and marked collapse, yet recovery followed in all. The fourth case was one of septic infection from a fibroid, which had broken down and was discharging into the abdominal cavity. In this case the antistreptococcic serum was used for twenty-seven days, but with no good result, and the patient was then operated upon, with recovery. He found that after the injection the temperature rose and then fell. He did not approve of washing out the abdomen, but carefully wiped off the parts with gauze wet in hot salt solution. Drainage should be ample. He called attention to the fact that the healthy peritoneum has a great resistivity to infection, but that after years of repeated attacks of pelvic inflammation it loses this resistivity, and then comes an attack of general peritonitis, often fatal. He considered the danger of operation, due to opening a pus sac, very small.

Dr. BEVERLEY MACMONAGLE said he had listened to a paper at the last meeting of the society, in which a number of cases were reported, the operation per vagina having been performed; most of the cases recovered. The abdominal operation had been performed in all the cases reported by Dr. Thorne, and they too had all recovered; one was therefore in some doubt as to which operation to choose. He thought that the vagina was not the point of choice for operation, however, for one could more easily operate through the abdomen and less damage could be done. Whenever possible, a portion of the ovaries should also be removed, for it was useless and a cause of recurrent trouble in not a few cases. He believed in flushing out the cavity with salt solution, and frequently left a quart of the salt solution in the abdomen, closing the wound entirely. When there was general peritonitis with true septic pus, he believed it was essential to thoroughly wash the cavity and leave the salt solution in when closing the wound.

Dr. J. HENRY BARBAT quite agreed with what Dr. MacMonagle had said, but thought it advisable to make the drainage through the vagina in a large number of these cases. It could be very easily done, was perfectly safe, and gave the best possible drainage.

Cincinnati Academy of Medicine.

Meeting of Nov. 21, 1898.

Dr. JOSEPH RANSOHOFF exhibited a male patient, about 30 years of age, on whom he had performed, a short time before, a partial operation of removal of the urinary bladder. Several years previously a suprapubic operation had been performed for supposed stone, but nothing found, and the patient had improved considerably after the operation, but of late his cardinal symptom, hematuria, had again come on. The blood, as a rule, was intimately mixed with the urine, so that suspicion of the kidney as the organ at fault was at first held. Occasionally, however, clots of blood were expelled, and even pure blood. On opening the bladder by suprapubic section, the trouble was at once discernible: a large tumor situated upon and infiltrating the anterior bladder wall. So extensive was this infiltration that anything like complete removal of the growth could not be performed without also taking away a section of the bladder. Accordingly the abdominal incision was greatly enlarged, and a large oval resection of the anterior wall made, including the tumor. The wound was then closed, the lower part being packed and drained with gauze. Healing ensued, leaving a very small fistula. The microscopic examination showed the tumor to be a carcinoma. As the history of involvement covers a period of about five years in all, it is possible that the primary growth may have been papillomatous in character.

Dr. LOUIS STRIKER read a paper on "The General Practitioner and the Optician vs. the Oculist," which was discussed by Drs. S. C. Ayers, Tangeman, D. T. Vail, Marcus, Drury, DeBeck, Christian, and the essayist.

Dr. ROBERT SATTLER reported a case of a woman who had first presented herself for proptosis. The inferior orbital plate had been pushed upward and forward, and by narrowing the orbital cavity, had caused protrusion of the eyeball. It was thought that the case was one of osteosarcoma, and operation was advised and accepted. The incision was begun a little above and an inch external to the outer margin of the orbit and was extended in a curved manner downward and inward, coming up along the side of the nose about on a level with the beginning of the incision. Exploration of the maxillary sinus revealed nothing beyond excessive rarefaction, so great indeed that a large hen's egg could have been easily introduced into the cavity. The orbital plate was found pushed upward and was relieved. The frontal sinus was also very large, readily admitting the little finger. No fluid or tumor formation was present in connection with either sinus. The external incision

was closed, leaving drain to both cavities. The lids were sutured together with interrupted sutures so as to avoid dangerous proptosis. At the present time, the stitches having been removed, the eye is gradually returning to usefulness.

Dr. F. W. LANGDON presented a patient, aged 71 years, who about a month ago, while in bed, was seized with coma; the rapidity of the seizure was unknown. On recovering it was found that he was afflicted with right hemiplegia involving face, arm and leg; that he also had right homonymous lateral hemianopsia; and anesthesia of the right arm and hand. Since that time he has been rapidly recovering from his paralysis, and is now able to walk, though with an ataxic gait. It was discovered during his recovery, that a peculiar form of aphasia existed, which greatly aided in locating the site of the lesion. He was able to remember but not to recollect. When a spoon was held up for his observation he was able to remember that he had seen such an object before, but could not tell just when nor for what use. Yet he knew what a spoon was when the name was spoken. He was able to say "spoon" without difficulty. He was able to answer simple questions with intelligence, but could not recall the names of objects even when they were put in his hands, and he had the muscular sense in addition to help him solve the riddle. A bell was rung behind him, and he was able to tell instantly what it was; but when the bell was showed to him and put in his hands, the tongue being held to prevent its ringing, he was not able to tell what it was. This condition was diagnosed as subcortical visual apraxia. There was also alexia present. There were some other symptoms present which made him regard the lesion as a thrombosis affecting the posterior artery of the internal capsule, also interfering to some extent with that part of the optic radiation going to the left angular gyrus. The hemiplegia was due entirely to pressure, for with the removal of pressure the man was regaining the use of his paralyzed limbs.

Dr. JOHNSTON again presented the infant he had brought before the Academy about two months ago (vide JOURNAL, Oct. 1, 1898, p. 807). In the interim he had operated upon the lumbar spina bifida; it was found to be a meningocele, only a few fibers of the cauda, however, being spread out over the sac. A fusiform section was taken out of the membranes and also out of the skin, and both wounds closed by separate rows of sutures. The child, now five months old, made a splendid recovery, healing occurring by first intention. The child had no convulsions after the operation. The wound was constantly contracting into a firm scar. It will be remembered that the child had also congenital clubfeet, congenital hydrocephalus and imperforate anus, the latter having been relieved a few hours after birth. As far as the mother was able to tell he is as intelligent as her former children, all of whom are healthy, were at the same age.

Dr. GUSTAVE ZINKE reported five cases of abdominal section and presented specimens: 1. Large interstitial fibroid, weight twelve pounds. 2. Small superitoneal, multiple fibroids. 3. Ovarian cyst with strangulated pedicle complicated with pregnancy. 4. Ruptured tubal pregnancy (early) with hemorrhage into peritoneal cavity, supposed to have ruptured during a curettement of the uterus; abdomen opened two days after the latter operation; recovery. 5. Small ovarian cyst; small subperitoneal fibroid.

Dr. E. H. SHIELDS presented two pictures of skin affections, the first in oil, irradicable pigmentation following a specific eruption. The disease had not been diagnosed by his former physician, and the patient had been taking Fowler's solution for a considerable period. The Doctor thought that the arsenic was probably the cause underlying the pigmentation. He did not think the condition could be relieved. It was but the second instance he had seen in over a thousand cases of syphilis. The second picture was a water-color illustrating a case of herpes tonsurans maculosa. A third case was reported and specimens presented, of small round uric acid stones about forty-five in number, evacuated from the bladder, but presumably from the kidney, though the patient had never had an attack of renal colic.

Detroit Medical and Library Association.

Regular Meeting, December 12.

Dr. L. J. LENNOX read a paper on "Contracted Kidney, with Special Reference to its Syphilitic Etiology," and said that where a chronic condition, resulting in a shrunken kidney, is found with extensive destruction of the tubular substance and overgrowth of the interstitial connective tissue, the condition may be described by any of the following terms: contracted kidney, cirrhotic kidney, granular degeneration of the kidney, red kidney, gouty kidney, arteriosclerotic nephritis and renal sclerosis.

In describing the contracted kidney most authorities claim that in the beginning the disease is obscure, no distinctive symptoms occurring until uremia shows itself, yet some authors speak of the bounding pulse from hypertrophy of the left ventricle of the heart and a slight swelling of the feet and ankles, as directing our attention to the kidney. The urine is acid, copious, except in the last stages, when it is scanty, low in specific gravity, occasionally showing the presence of albumin, which is constantly present later on in the disease. Albumin-like tube-casts are few in number. Hypertrophy of the left heart and sclerosis of the arteries is constantly present. The vision is impaired, the ophthalmologist often being the first to discover the real nature of the disease.

The main symptoms enumerated by the author were dizziness, headache, drowsiness, convulsions, stupor, delirium, vomiting, nausea and restlessness. As to the etiology, gout was placed at the head of the list, then lead poisoning, business care and worry, hereditary influence, valvular heart disease, stone in the kidney, alcoholism, exposure to cold and syphilis. The Doctor stated that most writers admit that the kidneys undergo changes both in the early and late stages of syphilis, but do not give as a cause of contracted kidney enough attention to syphilitic conditions. Syphilitic infection is the most potent cause in the production of arteriosclerosis, which is directly answerable for cardiac, vascular and renal lesions. Syphilis is termed a blood disease, but there is very little change in the blood except in the early stages, when there is a slight diminution in the number of red-blood corpuscles and a corresponding increase in the white.

The Doctor concluded with a history of one case out of three he had seen of contracted kidney, preceded by syphilitic infection, in which the patient inoculated his wife, who passed through all the different stages of the disease. One and a half years after the initial lesion the patient complained of a bad taste, loss of appetite, headache, constipation, accompanying a rise of temperature to 101 degrees; the patient was thought to have typhoid fever. About three weeks afterward the temperature was reduced to normal and even subnormal, but still the lassitude continued. The patient developed great thirst. There was an excessive flow of urine, but analysis showed no albumin nor sugar; casts were absent: specific gravity, 1010 to 1012. Diagnosis was interstitial nephritis. As the symptoms progressed the urine became scanty and indications of uremia appeared. There was no swelling of the feet or ankles, and no albumin was present in the urine. At present there is hypertrophy of the left ventricle of the heart and some paralysis, as dragging of the left foot and difficulty in swallowing and articulation. The diagnosis was changed to that of contracted kidney due to syphilitic lesion.

PRACTICAL NOTES.

Stitch Hole Infection.—Troller finds after extensive investigations that the infection usually proceeds from the skin, and that the most favorable results were obtained with aluminium bronze wire for sutures, which is antiseptic in itself.—*Cbl. f. Chir.*, December 3.

Orthoform for Toothache.—Hildebrandt relates that the raging pain of an exposed pulp in a carious tooth was arrested at once with an application of orthoform, dissolved in warm alcohol, on cotton. There was no further pain for two days, even in eating, when the tampon was renewed, as at first, with the same success.—*Deutsche Med. Woch.*, December 1.

Oxygen to Prevent Vomiting after Chloroform. Chavannaz reports twenty-three anesthetics, mostly for long and important operations, in which the chloroform was followed by the inhalation of the contents of a bulb of oxygen such as is used in hospitals. In fourteen there was no vomiting: four vomited once, and none vomited enough to interfere with the ingestion of food. *Gazette Méd. Belge*, December 8.

Vaginal Extirpation for Carcinoma Uteri.—E. Fraenkel states that 31.7 per cent. of 311 cases thus operated at the Berlin Univ. Gyn. Clinic have been permanently cured, that is, without recurrence after five years. The percentage of corpus carcinomata cured was still larger, 53. Its benefits are questionable when applied as a merely palliative measure.

Radiographs in Nephrolithiasis.—Ringel has established that oxalate stones cast as distinct a shadow as a bullet: uric acid

stones are less distinct, and phosphate stones cast no shadow at all, hence the absence of a shadow is no proof of the non-existence of a stone. The same is true of stones in the bladder. To ensure the best results the patient should empty his bladder just before being radiographed, and in case of nephrolithiasis, the thigh should be drawn up to the body to reduce the natural lordosis.—*Cbl. f. Chir.*, December 10.

Nafthalan in Eczema.—J. Hirschhorn writes to the *Deutsche Med. Woch.* of December 1 that he has been using nafthalan in fifty-two cases of eczema and found that it arrested acute eczema with copious secretions in forty-eight hours, the skin regaining its normal appearance in three weeks at farthest. In subacute and chronic cases the effect is less rapid, but still extremely satisfactory. It is also valuable in eczema of the scalp, scabies and psoriasis, and especially in professional eczema, enabling the patient to resume his occupation sooner than with any other remedy.

Is a Green Intestine Gangrenous?—Begoïn states that he found an eight-day incarcerated loop a "fine green Florentine bronze color" at the herniotomy. The loop was not reduced and the patient died four hours later, when tests of the green portion proved that it was not gangrenous. The portion of the intestine was filled with water at a strong pressure, and only an apparently sound part split. He also states that the intestine can be colored green with bile alone, and that a light green color does not necessarily imply any alteration in the intestinal wall. A yellow green, dark, black or bottle green are of worse significance, but at the same time they do not necessarily indicate a serious deterioration in the intestinal wall.—*Cbl. f. Chir.*, December 2.

The Toxicity of Appendicitis.—Prof. G. Dieulafoy has lately been emphasizing the intense toxicity that may develop in the course of even the most apparently benign case. In its usual benign form the toxicity is evidenced by the subicterus, urobilinuria and albuminuria. Icterus, testifying to the adulteration of the liver, is sometimes the notice of a most serious intoxication, affecting the nervous system, with cerebral, bulbar or typhoid manifestations. The only means to forestall these accidents is to suppress the toxic-infective focus in time. "No one ought ever to die of appendicitis." He distinguishes between the infective and toxic accidents, as the latter are much more rapid and fatal and necessitate more prompt intervention.—*Presse Méd.*, November 9.

A Quinin Wash for the Scalp.—The *Indian Lancet* for September 16 quotes from the *Revue de thérapeutique* the following prescription, which has been used with satisfaction to prevent the falling of the hair:

R Hydrochlorid of quinin	5 i	31
Tannic acid.	5 iii	493
Alcohol (70 per cent.)	1 1/2 pints	7464
Tincture of cantharides.	5 iiss	77
Pure glycerin.	5 iiss	77
Eau de cologne.	5 x	311
Vanillin.	gr 2	13
Powdered sandalwood	5 i	31

This mixture, after being well mixed and shaken, is allowed to stand for four days and is then filtered. It is rubbed into the scalp daily for the purpose named.

Acute Mania After Cataract Operations.—A man, aged 92 years, hitherto healthy, and yet very robust, was submitted to a cataract operation on the right eye. The operation was most successfully and quickly performed. Anesthesia was produced by six drops of a 2 per cent. cocaine solution. In the second night after the operation, severe maniac conditions set in. They lasted sixteen days. Dr. Fromaget attributes these conditions to a persistent constipation and retention of urine (auto-intoxication). During two days anuria prevailed. Afterward a small quantity of urine was voided. After injections of caffeine, the quantity of urine increased. Such psychoses are sometimes observed after cataract operation in old people.—*Annales de la Pol. de Bordeaux*.

Rinsing Apparatus for Microscopic Sections.—G. Cruz of Rio de Janeiro prevents the loss of microscopic sections of tissue which so easily escape during the necessary rinsing, by the following simple contrivance, described and illustrated in the *Zft. f. Wis. Microscopie*, 1898, No. 15: The fragment of tissue is placed in a conic test-glass, and a glass funnel is placed in the glass, just enough smaller in its circumference than the test-glass, to allow water to pass freely between the two, without space enough for the fragment of tissue to be swept along with it. The water enters through a small-sized glass tube, perforated at its lower end, connected by a rubber tube with the receptacle of water, and a larger funnel-shaped vessel below receives the water as it passes upward between the glass and the funnel and pours out over the edge of the former. —*O Brazil Médico*, November 1.

Wagner and Longard's Ether Inhaler.—The upper end of the mask is not open, but is shaped like a funnel with inhalation valves at the lowest part. The ether is dropped into this funnel, passes through the valves and drops below on a very fine wire sieve, on which it rapidly spreads out. A second sieve is at a little distance below, the space between holding a layer of gauze. As the air is inhaled it carries the ether vapor with it in the finest particles, and the anesthesia is complete in a minute and a half to three minutes in women and youths. Men require four to six minutes. The quantity of ether is only 5 to 10 c.c. for children; 15 to 25 c.c. for women and 30 to 50 c.c. for men and hard drinkers. The chief advantage of this inhaler is that the narcosis becomes complete while the patient is still quietly breathing, with entire absence of any period of agitation. —*Chit. f. Chir.*, December 3.

Rebreyend's Method of Circumcision.—This method is based on the principle of "total resection of the mucous membrane of the prepuce with almost complete conservation of the integument: sacrificing the minimum of skin to the maximum of mucosa." After anesthesia a narrow strip of skin is resected entirely around the preputial orifice, drawn out in front of the gland with forceps above and below. The integument of the penis is then pushed back all around as much as possible, leaving the preputial mucosa attached to the glans fully exposed. This mucosa is then slit from the front backward, with the scissors, to the back of the crown, and the two lateral flaps thus obtained are excised, leaving nothing of the mucous membrane except a narrow retrobalanic collar. The raw edges of this mucous collar and the integument are then sutured with fine catgut. A thin layer of salve or antiseptic powder is applied to the line of suture, which rapidly heals and is always hidden under the new fold of the prepuce, which is exclusively cutaneous. Loumeau reports twenty patients, including children and old men, thus operated, with the most satisfactory results. —*Gaz. Méd. Belge*, December 8.

Electrization as a Purgative.—G. Huerfauth of Eisenach has found that the galvanic anode introduced into the rectum will cure chronic cases of constipation and produce a prompt evacuation, even in normal persons when the bowels are comparatively empty. The sensation of a desire for defecation lasts after the evacuation and is of the greatest benefit in cases of neurasthenia and hypochondria, who recover their confidence in the restoration of their lost functional activity. Tympanism is abolished, and solid masses, even coprolithic formations, are expelled. The average treatment is two to five minutes in length; the current two to five milliamperes. If there is a sensation of heat, galvano-faradization is best at first, changing to the continuous current later. The patient is usually reclining on his back, the legs lightly flexed on the abdomen, a bolster under his knees if desired: or the treatment can be administered standing. The electrode for insertion in the rectum is large, conforming to the space inside. It is warmed, vaselined, inserted by the patient, and then held by the physi-

cian, who can thus control the contractions and ensure that it is in contact with the rectal mucosa. There are no injurious effects from this treatment, which he asserts is "not only a symptomaticum but a splendid curativum." —*Deutsche Med. Woch.*, December 1.

Antitoxin in Tracheotomy for Diphtheria.—At a recent meeting of the Ulster Medical Society, Mitchell (*Lancet*, Dec. 10, 1898, p. 1551) called attention to the prevalence of laryngeal diphtheria in the north of Ireland, as illustrated by a mortality of 3402 from this disease in Ulster during the past twenty years, while during the same period in all the rest of Ireland the deaths from the same cause numbered only 3320. The annual death rate per 100,000 in Belfast and the surrounding district is 14, while the death-rate for Dublin is only 7. The beneficial effect of antitoxin in the treatment of diphtheria and the consequent reduction in mortality were pointed out, while the utility of the antitoxin was more strikingly illustrated by the cases in which tracheotomy became necessary. For years there has been a firm conviction in the minds of the profession in Ulster that tracheotomy in diphtheria offers no reasonable prospect of saving life, and it was therefore performed only on rare occasions, and indeed was rarely recommended. Communication with the leading surgeons throughout the province of Ulster resulted in the collection of eighty-two operations performed for this disease prior to the introduction of the antitoxin. Among these there were only six recoveries (7.5 per cent.). A similar list since the introduction of antitoxin yielded a total of twenty operations, with fifteen recoveries (75 per cent.). The value of artificial respiration after the trachea has been opened in cases in which respiration has been suddenly suspended was particularly insisted upon, and records were given of cases in which this measure had resulted in a restoration of vitality in what appeared to be a death-sleep.

Unguentum Crede—Soluble Silver.—G. Schirmer has treated nine cases of cerebrospinal meningitis with inunctions of 30 gm. unguentum Credé in the course of three days, repeating an inunction of 10 gm. at each remission. Combined with this, very hot water compresses were applied to the spine; the nasal cavities were antiseptically cleansed as soon as the patient's condition permitted, and small doses of trional were given, if very restless. All were children, and recovered rapidly, with none of the after-effects so frequently observed with this disease. Edwin Klebs suggests that infection may be carried through the tissues as well as along the lymph and blood system (*N. Y. Med. Monats.*, November), by the leucocytes, which would explain the success of the inunction, and urges tests to demonstrate this, with Credé's soluble silver, as peculiarly applicable for the purpose. O. Werler considers that Credé has succeeded "with his systematically conducted chemico studies and bacteriologic experimentation in filling a gap in therapeutics that has been long and painfully felt by all practitioners, with the discovery of a specific which, without the slightest injury to the vital functions, removes the cause and cures the dreaded septicemic processes by its intense bactericidal power. In this respect Credé's argentum colloidal is absolutely without a rival. In this soluble metallic silver we have an internal therapeutic measure that can be relied upon to successfully control the blood-poisoning due to septic infective substances, if the diagnosis is made in time and there are no serious secondary affections." He finds also that the most effective method to apply it is in inunctions, by which means the medicament reaches the blood by percutaneous absorption, where it ensures an universal antiseptics and disinfection of the entire organism, by the formation of powerfully bactericidal silver salts. He only has three cases to report (*Deutsche Med. Woch.*, No. 40): acute sepsis, a septic affection and chronic multiple furunculosis. The progress of the affection was arrested with inunction, and complete recovery followed promptly in every case (vide JOURNAL, xxx, p. 1414).

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

No. 61 Market Street (Occidental Bldgs.), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, DECEMBER 31, 1898.

DEATH OF JOHN B. HAMILTON, M.D., LL.D.

It is our painful duty to record the death of the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION on the evening of Dec. 24, 1898, at his residence at Elgin, Ill. The immediate cause of his decease was hemorrhage from a perforation of the intestine, communicating with a large abscess outside of the bowel, which terminated life after an illness of less than one month.

It seems hardly necessary at the present time to enter upon a detailed narrative of the life of one who was so widely and well known throughout the entire country. Born in Jersey County, Ill., on Dec. 1, 1847, his years numbered only fifty-one; but they were years that were crowded with incidents sufficient for centuries of ordinary human experience. Descended from a long line of distinguished Scottish ancestors, his father's family was brought up on the rich prairies of the Mississippi Valley, enjoying such opportunities for early education as were afforded by the village school, the country academy and the classic courses founded by Prof. JOHN GRANT, a learned Latin teacher from Edinburgh, who had found his way to the heart of America. Thus trained and exercised in all the practical affairs of country life, from the hay-field to the village printing-office and drug store, young HAMILTON, at the age of 17 years, found himself drawn into the vortex of the Civil War, where he acquired that experimental knowledge of military life and discipline that was of such value to him during the remainder of his days. At the

close of the war he returned to civil life, with an appetite for study intensified by the exercises of the field. Entering Rush Medical College, Chicago, he was graduated three years later with high honors, and immediately began the practice of medicine in his native county. Soon, however, he concluded to essay the career of a military surgeon, and returned to the army of the United States as an assistant-surgeon. Transferred from post to post, he rapidly became acquainted with the vast extent of our territory, and in positions of responsibility gave evidence of that rare ability for the organization and direction of great enterprises that was the prominent feature of his character.

In the year 1876 he transferred his connections, upon most honorable terms, to the United States Marine-Hospital Service. In this service his superior powers at once asserted themselves. He was

DR. JOHN B. HAMILTON.

rapidly transferred by promotion through the round of important stations, rising in rank till within three or four years he had reached the position of Surgeon-General of the United States Marine-Hospital Service. This high office he retained through several different administrations of the National government, winning golden opinions alike from political friends and foes. During this period he effected a complete reorganization of the Service, and contended successfully against repeated invasions of the country by epidemic cholera and yellow fever. Under his direction a rational system of quarantine and isolation was adopted, the necessary encampments were established, and panic gave way to intelligent confidence. In the halls of legislation his influence was as beneficently potent as in the field of medical action, and it is no exaggeration to claim that the most important acts for the security of the public

health by the National Legislature during the past twenty years were originated and guided by the enlightened intellect of Surgeon-General HAMILTON.

But the attractions of civil life finally drew DR. HAMILTON from the sphere in which he had been so long pre-eminent. Always fond of books and the scholastic side of existence, his library grew till it became one of the largest private collections in America. He was Professor of Surgery in the University of Georgetown, and was as actively engaged in private surgical practice as the arduous duties of his high office would permit. Called to the chair of the Principles of Surgery in Rush Medical College, he resigned all his positions in Washington, and removed to Chicago in 1892.

It is at this point that the principal interest of the JOURNAL in DR. HAMILTON is centered. For many years an active member of the AMERICAN MEDICAL ASSOCIATION, he was well and widely known to the members of that National body. An almost universal acclamation summoned him to the editorship of the newly-fledged publication which had undertaken to be the organ of communication between the ASSOCIATION and the medical public at large. The JOURNAL was young in years, and its management was inexperienced, and with comparatively little weight beyond the limits of the editorial sanctum. DR. HAMILTON at once deployed all his administrative faculties, placed everything upon a business basis, and before his death enjoyed the satisfaction of seeing the JOURNAL in the front rank of the medical publications of the world.

Could he have remained satisfied with this victory, DR. HAMILTON might possibly have continued for many years upon earth in the full exercise of his beneficent powers. The leading sanitarian of the country, in all matters of National interest, his advice was sought in every quarter. No medical gathering of National or International importance was complete without his presence. His vigorous form, his genial countenance, radiant with energy and good-will, his persuasive voice, were never-to-be-forgotten features in every such assembly. At home his professional duties, his hospital work, his extensive private practice, were enough to wear out any ordinary man; but he was ever ready to expend his energies in behalf of any worthy cause that appealed to him for aid. In this way he gave much time and thought to the organization of the new Public Library in Chicago, and was most efficient as President of its Board of Trustees. To the surprise of his friends, despite this accumulation of cares, he accepted, in 1896-7, the position of Superintendent of the Northern Illinois Hospital for the Insane, at Elgin, Ill.—an office that heretofore was always considered sufficient to occupy the whole time of an ordinary official incumbent. But the DOCTOR speedily showed his mettle by a reorganization of the administration, that secured

improvement in the care of patients, while leaving time for all his other labors—thus illustrating the old observation that among first-class administrators the busiest men still have the most leisure.

Now, alas, this career of action has reached its limit. As we look back upon its years we can more fully than ever appreciate its magnitude and its beneficent efficiency. DR. HAMILTON was fortunate in finding full scope for his remarkable power as a founder and organizer of incipient enterprises. He was fortunate, also, in being permitted to witness the success of his efforts, and he was doubly fortunate in being called to his reward before age or misfortune or any of the ills of life could dim the splendor of his reputation. He has gone, but his works live, and will forever exhibit the impress of his constructive power.

THE PATHOLOGY OF THE PINEAL GLAND.

If the proverb, "Happy is the nation that has no history," be true for other organisms in general, then the pineal body ought to be regarded as a most fortunate organ. That it has had a history and a most curious one, we have abundant proof, but that was long ago, in the Age of Reptiles, to which the memory of man runneth back or reverteth only under the influence of strong drink, and for the last quarter of a million years, at least, it has absolutely ceased to have a physiology or even a pathology. It lies among the brain tissues as inert and almost as irresponsible to the forces about it as a fossil in the chalk beds. That it can continue to so exist generation after generation is proof either of services of extraordinary value rendered in the past, or some as yet unsuspected function in the present. Comparative morphology assures us that it was probably once a median or "vertical" eye, which still exists in some nearly extinct lizards (Hatteria) and possibly at an even remoter period the opening of the primitive mouth, of which its interesting relative, the pituitary body, was the gullet. That it originally reached the roof of the cranium is of course certain, having been pushed down into its present central position by the huge development and backward growth of the originally anterior cerebral hemispheres, which now cover, in our own species, even the cerebellum or "hindmost brain." But unfortunately these facts give us no clue whatever to its possible rôle in the body economy, for it obviously can not now function in any way as either an eye or a mouth, or anything connected with either.

Nor is there any help to be had from a study of its histology. According to the latest researches (OGLE, LORD) it consists of a dense connective tissue capsule from which fibers pass into the interior and form a loose reticulum for the body. In the meshes of this network are lodged rounded and oval nucleated cells,

whose protoplasm shows a tendency to become either colloid or amyloid, and by fusing with that of other cells gives rise to the *corpora amylacea*, or "starch-grain," concentric-layered bodies. In the fibers of the stroma are found the calcareous particles known as "brain sand." Nothing that can be clearly identified as nervous tissue remains, although there are a few large columnar cells resembling the "rods" of the retina. Like its now celebrated congener, the pituitary body, it was originally a hollow organ and occasionally traces of the central cavity are yet found.

On account of its central position and the way in which it is wrapped up in the choroid plexus, any attempt to remove it in animals must be attended by such serious injuries to the brain and its internal circulation as to give little hope of any reliable results from experiments in that direction.

Its pathology seems almost equally characterless. It may perhaps be said to possess the usual tendency of all vestiges to give rise to tumor-formation, for considering its small size and sheltered position, a relatively large number of new growths have been reported. The commonest of these, however, are simple cysts formed by dilatation of the central cavity, then comes sarcomata, then gummata, and the only form that is at all characteristic of the gland is the psammoma, or concentrically-layered tumor, with or without calcareous deposits.

Worse yet, with the possible exception to be mentioned later, none of these tumors have given rise to any recognizable symptoms whatever pointing to any disturbance of brain or glandular function, other than that due to the pressure of the growth upon surrounding tissues.

A recent meeting of the Pathologic Society at London was devoted entirely to the pathology of this gland and fourteen cases were reported by the members present, specimens being shown from ten of them. Seven were cysts, four sarcomata, one glioma, one gummatous enlargement and one calcareous deposit. One of the cysts was interesting from the fact that its inner surface was lined with cells containing large amounts of pigment, in the very situation where the choroid coat lay in the ancestral eye, and curiously enough, several of the sarcomata were pigmented ones. After the reports of cases were all in the president called for remarks upon the general subject, but the absolute silence which followed was eloquent of the state of our knowledge of the gland even today. In all the cases reported there was only one symptom which was in any way peculiar or was common to more than two of them, and that was prolonged drowsiness, which was present in four. This was of long duration, lasting in one case for three months, and was of unusual character, as it never approached coma and the patient could be readily roused at any time, or would even answer questions without apparently awakening. As Dr. OGLE, who

reported six out of the fourteen cases, pointed out, this was most probably due to pressure upon the choroid plexus and interference with the circulation of the ventricles, but it is an interesting coincidence that Dr. PATRICK MANSON has reported the pineal body as found greatly enlarged in two cases of the singular African "sleeping-sickness." The drowsiness of this disease is precisely of this peculiar, easily-roused and chronic character, lasting for months and gradually deepening into asthenia, unconsciousness, convulsions and death. As there are two advanced cases of this disease in the Seamen's Hospital at the Albert Docks at present, the cranial results of the autopsies will be awaited with much interest.

VALUE OF TRANSFUSION.

This operation was known as long ago as the year of the discovery of America, having been performed at that time, according to some authorities, on Pope Innocent VIII. It was not used to any extent, however, until the beginning of the present century, while it has only been of late years that its value in its various modifications has become very widely recognized. At first performed only for dangerous loss of blood, it has in addition proved most valuable in shock, in uremic and diabetic coma, and in the various affections accompanied by sepsis. During the infancy of the operation, direct transfusion of blood from vessel to vessel was practiced, but this was soon discarded on account of its great difficulties and danger, and some bland and harmless solution was substituted. For when blood was transfused, thrombotic and embolic processes were of common occurrence and often resulted disastrously. In addition it was found that the injected blood corpuscles were rapidly disintegrated, naturally giving rise to dangerous embolic symptoms, and further, that any good accomplished was done by the fluid portions of the blood alone. These investigations were pursued still further until it was at length discovered that it was the quantity, and not the quality, to which the beneficent results could be attributed, and that the fluid acted by increasing the intracardiac and intravascular pressure. At the present day a normal or 0.6 per cent. sodium chlorid solution is used.

Another improvement in operation was introduced when it was found that the fluid could be injected into the subcutaneous tissues, preferably those of the right chest, abdomen and buttocks, from which tissues it would be rapidly absorbed. The advantage in this method is that it can be quickly and safely done, and that it can be performed while operative procedures are directed to other parts of the body. The solution is rapidly brought to the boiling point and then cooled to 100 degrees F, when it is ready for using, all instruments having been thoroughly sterilized by heat. Some operators pour the solution into a large funnel connected with the canula by a long rubber tube

and holding the funnel several feet above the patient, use the pressure thus created to enforce the fluid. Perhaps a better way, and certainly a more rapid one, is the use of the ordinary Davidson syringe attached to the canula.

When the indication is most urgent, and particularly where there are septic symptoms to be combated, an emptying of the vessels of their deteriorated blood and the injection of the saline fluid directly into the vessels (veins) has been advocated, and in a case recently reported by YOUNG (*Maryland Med. Journ.*, Nov. 19, 1898), performed with the greatest success. The patient, a boy of 15 years, had been operated on for purulent appendicitis, the pus fortunately having been walled in by extensive adhesions. Immediately after the operation the patient was in fairly good condition, but toward evening rapidly became worse. There were, however, no local signs that the peritoneum had been involved. When the pulse had reached almost 150, with a corresponding high temperature, he was given a nutrient enema, followed by the injection of 700 c.c. of saline solution into the right breast, and by lavage of the stomach. This brought about a considerable improvement in his condition. The next day after the operation he again became progressively worse, and the peritoneum still being apparently free, it was thought that he had developed a general septicemia. Venesection and transfusion were then decided upon for the double purpose of first withdrawing, and secondly diluting the poisonous material remaining in the circulation. The right basilic vein was opened, but only about two and one-half ounces of blood could be abstracted, so weak was the heart's action; 1300 c.c. of saline solution were then slowly injected, and during the operation itself the condition steadily improved. The next morning the symptoms again becoming dangerous, 2500 c.c. were used intravenously, with the result that the boy was soon practically out of danger.

The history of this case has been entered into rather in detail for an article of this kind, but all must admit the importance of the lessons taught by it. In the first place, very few cases, if any, have been reported in which so large an amount of fluid has been injected. One of the most important points in this double method of venesection and transfusion is that they can be done simultaneously, using one arm for the former, the other for the latter. In this manner the blood-pressure can be readily maintained, a most valuable consideration in a state where circulatory functions are so greatly below par. A third point, as suggested by YOUNG, is that the use of large quantities, intravenously, washes out the veins, as it were, and perhaps to a small extent neutralizes the poisons contained in the blood—certainly dilutes them. In most of the conditions in which this method of treatment was employed, the kidneys, as a rule, are not functioning to an extent anything like normal. The

introduction of this fluid into the body by increasing the blood-pressure and the amount of fluid into the body tissues as well, to some degree, acts as a diuretic, and even the smallest gain in this direction often means the saving of the patient. YOUNG also touches upon an important speculation as to how much dilution the blood is able to stand. He estimates that the body of a normal adult man contains about 4500 c.c. of blood. His patient, he feels sure, had much less, yet 4500 c.c. were thrown into his vascular system and with the greatest benefit. He argues from this fact, that his primary injections resulted in but temporary benefit, that large amounts of the salt solution should be used at the beginning, advocating in an adult man as high as 7000 c.c. He does not think that the small quantities so frequently given will ever be very efficacious. Among other conditions in which these injections might prove of service, the toxic conditions commonly observed in the acute infections, typhoid, and particularly the coma of pernicious malarial fever, must receive special consideration. Of their use in the former disease there is no literature at hand, but in malarial coma several cases are on record with favorable results.

Lastly, the injection of these fluids into the arteries deserves brief mention. It was thought by HUNTER that this method lessened the danger by bringing the blood more gradually into the general circulation. Even if some air were admitted it would here work little or no harm, while if air were received into the veins, venous thrombi might form, which would undoubtedly seriously embarrass the heart's action. The radial artery is the one recommended by HALSTEAD for injection, and the latter authority lays particular stress on the value of this form of operation in fat subjects.

BUBONIC PLAGUE.

The appearance of this disease in Vienna has created some sensation, and has startled experimenters and laboratory workers. It appears that Drs. ALBRECHT and GHON brought from Bombay the bacilli of this disease, and began a series of cultivations and experiments in the laboratory. Animals were inoculated and examined after death and the specific bacillus was isolated and transferred to different animals, and inoculation as a means of prevention was studied.

This work has been going on for over a year with many very interesting results. The two physicians and an attendant were the only persons who came in direct contact with the virus. The attendant fed the animals experimented upon, handled them, and cleaned the floors, and observed all the precautions supposed necessary to prevent accident. He also disposed of the carcasses of the animals. Suddenly he was seized with the plague and died. Two nurses who attended him were taken with the same plague

and died also. Dr. MULLER, an expert, who had been in India studying the same epidemic on the spot, and who visited the attendant, was also seized with the same disease and died.

All the three physicians had been engaged in the profuse cultivation of this bacillus in its most virulent form, and in the study of means of prevention, and were experienced bacteriologists. They knew of the danger and had provided against accidents up to this time. It appears from a court examination that the attendant, although a trained man and very careful, was often under the influence of spirits. It is supposed that he must have neglected some sanitary precaution in laying down his pipe in an infected place and using it again, or in failing to wash his hands after handling the animals. The nurses and the doctor were equally incautious and lost their lives through this neglect.

The facts pointed out by the foreign journals commenting on this event are that very few accidents occur in the extensive laboratory examinations now going on in all the large cities. The most virulent poisons and bacilli are cultivated and handled without accidents, showing what intelligent care and exact work can do. Of course this event gives renewed emphasis to the danger from this bacillus, and shows that the plague can be grown and spread in any community by the slightest neglect of sanitary conditions.

The *London Times*, after describing this incident, makes a strong plea for greater caution and care in the many infectious diseases which pervade the community and are neglected. The soil for the growth of diphtheria, tuberculosis, and other diseases, is found in all communities, only needing the germ to start into great activity. The hospitals and other places where medical men are exposed, are not yet managed as they should be to avoid the danger of these virulent germs. Every year physicians and nurses die from neglect and carelessness, both personal and official. The teachings of laboratories are enforcing the fact in many ways, that most diseases are entities which can be provided against and prevented, also that the germs can be transmitted and carried, cultivated and grown with certainty.

The great study of the present time is to trace these germs back to their sources, to stop their growth, to direct and control them. This plague is one of the great epidemics of tropical countries. It is mysterious, virulent, and usually fatal. A study of the bacillus and its culture has already thrown much light on the causes, and gives promise of prevention by inoculation, and also the possibility of some serum being found to render the person immune from its infection. To the investigations of the laboratories we must look for light on the subtle bacterial enemies, and the means to control and prevent them.

COMMENTS ON THE WORK OF THE ARMY MEDICAL DEPARTMENT.

We have read with much interest the comments of our contemporaries on the work of the Army Medical Department during the Spanish War, as presented to the profession in the abstract of the Report of the Surgeon-General published in the *JOURNAL* of December 3. So far as we can learn, the general view of the profession agrees with our own that the document is an able presentation of the facts, and a clear and impartial statement of all the conditions bearing on them, such as might have been expected from a scientific man whose only object was to reach the truth and enable others to do so also. The difficulties which beset the path of the Surgeon-General of the Army are set forth so clearly that one must be an unthinking reader who fails to appreciate the causes which led to unsatisfactory results in particular instances although these causes may not be specified in each particular connection.

The conclusion which we have reached appears to be that which has been attained by most of our contemporaries, that in view of all the facts it is but just to say that "the efforts of the Surgeon-General and his medical officers to meet the terrors of war were extraordinary, and challenge admiration." That these efforts failed to fulfill their intention of preventing the occurrence of preventable diseases was due to the impossibility of controlling the ignorance of the many by the knowledge of the few. We, as a profession, pride ourselves on our recent advances in sanitary knowledge and particularly as to the prevention of typhoid fever, and we teach that sporadic imported cases are the only cases that should be permitted to appear on the hospital registers of a well-disciplined camp. The Surgeon-General of the Army and his officers knew this as thoroughly as we do, but it was impossible for him and them to hold in control the ignorance of the large number of undisciplined men aggregated in our camps during the past few months. We reached this conclusion long before the report of the Surgeon-General was made public. On Sept. 24, 1898, we stated, in these columns: "It is very evident to one who looks on from the outside, that the difficulties encountered by the Army Medical Department were due to the impossibility of having, in so short a time, an experienced and well-disciplined medical force sufficiently strong in numbers to control the sanitary situation in an aggregation of a quarter of a million of men hurriedly thrown together in military camps." Although the profession as a whole may take a high position on sanitary grounds and claim the ability to protect from certain diseases, the ability of the individual medical man is limited by many and powerful combinations of conditions. One medical weekly considers it shameful that typhoid fever should have spread in our camps, but we do not take such high ground as

this. Typhoid fever has heretofore been a dangerous visitant in every camp of newly-raised troops. When sanitary knowledge is generally diffused and sanitary rules are universally appreciated and followed, we may expect a change in this respect; but recent events have shown that it is too soon to expect this now. All we can do is to strive earnestly for betterment. The daily press has thrown the blame of the occurrence of preventable diseases in our camps on the shoulders of the Surgeon-General, forgetful that if the doctor is to be held responsible, it is not the Surgeon-General, but the regimental surgeon who should be arraigned, for if each regimental surgeon had been an efficient practical sanitarian, able to combat successfully against his insanitary surroundings, there would have been no typhoid fever in the brigades, divisions or corps. One New York daily claimed that the difficulties encountered by the Medical Department were due to a want, on the part of the Surgeon-General, of that general executive ability to put his extensive knowledge to effective use. A valued Eastern journal replied pertinently to this by comparing the conditions suddenly placed before the Surgeon-General of the Army at the outbreak of the war, with those confronting the manager of a large department store whose business, suddenly increased ten-fold, had to be carried on by a 900 per cent. addition of awkward and unskilled labor to his regular force of trained workers. The powers of one man, however forceful, intelligent, skilled and highly educated, are limited. He might be capable of directing and organizing an enormous force of trained employees under trained subordinates, but if the bulk of the material is raw, and unused to the special methods and routine of the work, it is beyond the limit of human power that one man should be able to control the working. Not only was the Surgeon-General unable to do this but each of his subordinate officers, chief surgeons of corps and divisions and in charge of large hospitals, had to cope with the same difficult duty of attempting to make bricks without straw, or to make skilled out of unskilled labor, while hampered by an insufficiency of even the raw material.

We regret to find one medical weekly reiterating this charge of the daily paragrapher and laboring heavily to sustain the position assumed, to-wit, that with an earnest and forceful man at the head of affairs the medical history of the war would have read differently. An astonishing amount of ignorance is displayed in the attempt to build up the argument: ignorance of the history of the Medical Department, of the history of the present Surgeon-General, and of the history of the war as stated in the report which gives rise to the criticism. Medical men, in their intercourse with the laity, have frequently occasion to note how the intricacies of a difficult technic subject can be overlooked and the whole

be grasped to his own satisfaction by one who has but little knowledge of the subject. Bold assumptions are brought forward to clear away difficulties and make the path straight. Some thoughts of this kind arise in our mind as we read that the inadequate number of officers of the Medical Department ought to have been recognized by the Surgeon-General before the events of the war forced its recognition upon him. The assumption that nothing was done by Surgeon-General STERNBERG or his predecessors in office is not borne out by the history of the Department. Again, the editor brings into prominence the rush service, which was so creditable to the energy of the Surgeon-General, as demonstrating only a discreditable lack of intelligent preparation. Every newspaper knows that the hands of the Secretary of War, as of the Surgeon-General, were tied until Congress had taken action in the case. The Secretary of War can no more be blamed for failing to have 250,000 disciplined men on hand, prior to the declaration of war than can the Surgeon-General for failing to have a field medical equipment for such an army. Neither could act until Congress had given the authorization and provided the funds. The ignorance displayed becomes somewhat less childlike when the credit given to Lieut.-Col. J. V. D. MIDDLETON for his able management of medical affairs on the Pacific Coast and in fitting out the Philippine expeditions, is twisted into a reflection on Dr. STERNBERG's administration. The insinuation is made that Dr. MIDDLETON was too far away to be hampered by central office bonds. This is strange and suggestive of an animus, for in the Surgeon-General's report are numerous instances of difficulties surmounted by subordinates as soon as they put themselves in communication with the central office in Washington. The prime reason why the medical supplies of the Philippine expeditions were always on hand when required was because Dr. MIDDLETON was independent of the Quartermaster's Department. His depot was within a block or two of the wharves, and instead of having to turn supplies over to the Quartermaster for transportation, he was able to have them delivered direct.

The existence of an animus suggested by the insinuated assumption just mentioned is strengthened when we find the editorial columns lowered to the following personality:

When a man who had reached the Surgeon-Generalcy through political methods, whose life training had been that of a laboratory man, whose life had been practically devoted to research work in bacteriology—and good work it had been—is brought suddenly face to face with the problem of the nation in war, it is not surprising that he should have found it impossible to meet the conditions.

Those who know most of the history of the Army Medical Department know that politics had nothing to do with Dr. STERNBERG's elevation to his present high position. His selection by Mr. CLEVELAND was due to the ability which he showed in discharging

duties in connection with National and international sanitation. Nor has his life training been that of a laboratory man, for his work for twenty years had been that of an army surgeon until his assignment on the Havana Commission imposed bacteriologic work upon him; and this new work, as the world knows, was done as efficiently as that earlier work which, though less generally known, sufficed to bring him into prominence as the best man for this important assignment.

Few of our contemporaries have discussed the remedial measures for the conditions described by the Surgeon-General. The medical weekly last cited proposes a vague reorganization with, "A commission of a dozen or more men, leaders in the profession, experts in special branches—in hygiene, sanitation, medicine, surgery, pathology and bacteriology—might be selected throughout the country and made an advisory body." We submit this proposition of a commission of able men who know nothing of military matters for what it is worth. For our own part, the remedial measures appear to be simple: Strengthen the Medical Department of the Army by making its numbers sufficient, and increase its efficiency by liberating it from its dependence on the Quartermaster's Department.

CORRESPONDENCE.

The Commission Evil.

NEW YORK CITY, Dec. 19, 1898.

To the Editor:—In response to my request for specific information about instances in which the specialist has paid commission to the general practitioner for referred cases, I have received several communications which indicate that the practice is not uncommon in a section of our country which is renowned for its "hustling" spirit. Personal inquiry among representative members of the profession in New York convinces me that my first impression was right, and that a division of the fee is never likely to become a practice here, excepting in instances where the patient agrees to pay a definite sum for the entire management of the case. This is rare, and would be an openly conducted transaction. I am in a position to see two sides of the matter. I have dropped from my practice everything excepting operative surgery, but during the year a good many other sorts of cases come in, which are referred to men who I believe are best authority. If any one of these men had been in the habit of offering a commission it certainly would have come to my knowledge, and further, he certainly would never have another one of my cases. On the other hand, I am constantly in contact with physicians who bring cases from all over the country, and not one of them has ever suggested that he would like a commission. As some of these physicians have come from the commission-infected area, they must have lost the symptoms on arrival in our atmosphere.

Payment of commissions would undermine the very pillars and foundation of responsible medical service, and would instantly bring us down into competition with charlatans. It is apparently a fact, however, that the commission evil has gained a foothold in a small part of the country, and perhaps very good land has been invaded by the Russian thistle. In order to keep reputable specialists who are subjected to the unfortunate influence of the commission evil, I propose that at the

next meeting of the AMERICAN MEDICAL ASSOCIATION a resolution be adopted to the effect that any practitioner of medicine who gives or receives a commission for cases referred to or by him, shall be expelled from membership in the ASSOCIATION. I also propose that specially printed, conspicuous cards bearing a copy of this resolution be given to the secretary of the ASSOCIATION for distribution to applicants. Any one who needs to protect himself can display the card in a manner suitable to an occasion.

ROBERT T. MORRIS, M.D.

Carcinoma of Breast and Tubercular Abscess.

SAC CITY, IOWA, Dec. 20, 1898.

To the Editor:—The apparently increasing tendency of tubercular abscess and carcinoma of the mammary region leads the writer to briefly recite the history of a case on whom he operated for such affections:

Mrs. S., white, 30 years of age, called at my office for treatment for rheumatism, complaining of intense pain in the chest. She had constant dread of cancer of the breast. On the right breast, just below the nipple, a growth was noticed, about the size of a walnut. The other breast was normal. There was enlargement of ankle-joint, pain in the fingers, but the glands did not seem to be enlarged. There was discoloration of the right nipple, which was somewhat retracted. There was a history of tuberculosis on the father's side, and one aunt and sister had been operated on for cancer. Her urine was acid in reaction; sp. gr. 1025; excess of urates; pulse 80; temperature 100 degrees. The child had been taking the left breast, so I advised removing it at once and recommended thorough operative interference. She submitted, and on Nov. 28, 1898, I removed the growth from the breast. Abscess was also found in front of the tumor.

She rallied from the effects of the operation, and after three weeks was able to attend to her household duties and seems to be gradually improving.

I examined the specimen and found tubercle bacilli in the abscess around the growth. In the middle of the growth a specimen was taken and prepared for microscopic examination, and the cancer cells could be plainly seen. Is there any connection between tuberculosis and cancer in regard to the germ theory?

LEWIS E. MAKER, M.D.

PUBLIC HEALTH.

Plague Epidemic in Samarcand.—The prompt and effective measures of the Russian Government seem to have stamped out the plague in Russian Turkestan. In the first three weeks 219 died, but only 19 since, and no new cases have been reported of late. Medical observation stations were established all over the country, forming a close cordon around the infected village and along all the roads, stations and ports on the Caspian, with flying medical squadrons constantly on the alert, and reserves of physicians in all the principal Russian and Siberian cities. The *St. Petersburg Med. Woch.* states that the physicians on duty in Samarcand are to receive 3000 roubles for their three months' service.

The Spread of Tuberculosis.—Dr. Russell, city health officer of Glasgow, Scotland, in an official report, corroborates many long entertained views of investigators. He points out that, in respect to phthisis, which is the chief form of tuberculous disease from which aerial infection can arise, the measures of prophylaxis may almost be summed up in individual care to prevent the dissemination of dried sputum in dust, and in the general adoption of improved dwellings to avoid overcrowding and to insure ample sunlight and free movement of air; in fact, the risk of direct communication of the disease from the

sick to the healthy is really as nothing, compared with the overloading of the atmosphere with infected dust, which may be introduced with food as well as inhaled. Another notable point made in this report is that of the factor of individual vulnerability—the removal of the natural barriers to the entrance of bacilli by catarrh and ulceration, and the lowered vitality of blood and tissue, which enables the invading microbe to prevail in the struggle for existence.

Notes for Health.—A journal for invalids offers the following *mélange* to its readers: "Rest is a fine medicine. Let your stomach rest, ye dyspeptics; let your brain rest, you wearied and worried men of business (Carlyle). . . . A cup of very hot milk taken at bedtime will effectually prevent sleeplessness. . . . An old physician once said: 'If people fully realized what it means to themselves to laugh, and then laughed as they should, 98 per cent. of the doctors would have to go out of business'. . . . A plentiful diet of onions served in various ways, will protect children from many ills (*Boston Cooking School Magazine*). . . . The perfume of flowers adds activity to all organs, especially those of digestion. For this reason, among others, the guests at banquets in ancient times were crowned with roses."

Dangerous Filters.—Persons who rely upon domestic filters to purify water for household use will be interested to learn that, on the authority of the State Board of Health of Maryland, such filters may steadily lose efficiency until they become first-rate culture-beds for bacteria. An example cited is that in the case of a man in Baltimore who sends the whole water-supply of his house through a large filter, and subsequently puts his drinking water through one of the small domestic filters common in the market. A test showed that on a day when the city taps were running 510 bacteria to the cubic centimeter, the large filter was delivering 9900 bacteria in the same quantity of water. When the large filter was repacked, only nine bacteria per centimeter got through it, but this same water, when passed through the small filter came out with seventy-one bacteria per centimeter. A further example cited is from the office of the Baltimore Health Department, where a filter, supposed to be the best in the market, was in use. The effectiveness of that filter was so short-lived that the precaution was observed of boiling the water after it was filtered.—*Sanitary Record*.

New Orleans Board of Health and Yellow Fever.—This Board has published a circular addressed especially to the medical profession, anticipating a visitation by yellow fever the coming year. It signalizes the importance of educating the public in preventive measures. Some of the suggestions offered are the following: "It is a well-known fact that sunlight and oxygen destroy the germs of disease. In the case of yellow fever, cold is a potent factor in such destruction. Let us then give Nature a chance, during the present winter, to destroy with her own inexpensive agents any possible remaining vestige of infection left over from the summer. Let our houses be thrown open on every cold and clear day as much as is practicable, more especially the bedrooms. Let the clothes and bedding, curtains and all woolen, linen, and cotton materials be frequently aired and sunned. And most particularly let the clothes worn during the past summer be frequently subjected to the disinfecting influences of cold, fresh air and sunlight. Trunks, chests, armors, closets and bureau drawers should be opened and emptied of their contents during cold and clear weather; and fresh, cold air should be permitted to circulate in the remotest corners of the house among articles which can not be moved to the sunlight."—*N. O. Med. Surg. Jour.*, December.

Radical Measures for the Obliteration of Malarial Attacks.—Levkovicz, in the *Przegląd Chirurcki*, offers a peculiar recommendation for the radical cinchonization of the entire population of

a fever-infested district. His scheme is to so organize the procedure that during one and the same winter all cases of malarial fever should be brought to a conclusion, either by recovery or, in fatal cases, death. In this way the site of infection would be destroyed, and in the coming spring no new cases of malarial disease would be observed. But, as it is next to impossible to locate all malarial patients in a given region, he suggests and recommends submitting the whole population in said malarial regions, *notens volens*, to a treatment of quinin. For adults, he would prescribe one gram, or 15 grains, per diem; children, according to their age, a corresponding quantity. This treatment should be employed as a prophylactic during a fortnight. In the old paternal governments of Europe such a suggestion, if approved by the home secretary, may become a sanitary police regulation and be enforced; but a similar suggestion would have little chance of successful hearing in these United States, where personal and individual liberty is so highly prized and so jealously guarded that even a universal vaccination of the virus of smallpox can not become, or at least has not become as yet, a matter of legislation, and only by the indirect means of exclusion from the public schools, or in the army and navy by direct regulation, has the administration or have the State sanitary authorities been able to make propaganda in this respect. But the mere idea to submit a whole population, or part of a population, whether they wish it or not, when yet healthy, to such a treatment, would seem to the majority of the people utterly absurd.—*New Orleans Med. and Surg. Jour.*, December.

Medical Inspection in Municipal Schools.—The municipal authorities of Berlin have decided to appoint medical officers to the municipal schools. This step will certainly meet with the general approval of the medical profession, which has for a long time past recommended medical supervision of schools. According to the instructions drawn up by the municipal school board, the duties of these medical officers will be as follows: 1. They will examine children as to their state of health before they enter a school; 2, in cases of bodily or mental abnormalities they may recommend the adoption of special instruction; 3, they will have to look after children who are absent from school without sufficient reasons; 4, they will have to advise the head master in cases of infectious diseases; 5, they must give notice to the school board when they have found the health of the children unfavorably affected by the unhygienic conditions of a school; 6, they will have to be present at a certain hour at the school once a fortnight so that the masters may obtain their advice in individual cases; 7, they will have to control the class rooms without reference to the hours of instruction; 8, all the medical officers of schools will have to meet regularly under the presidency of a member of the school board to discuss matters relative to the hygienic conditions of schools, etc. The duties of these medical officers will thus be rather complex, and a good deal of tact will be required on the part of these gentlemen to avoid friction with the teachers or with the family medical attendants of the children. A large proportion of school managers and teachers is opposed to the appointment of these medical officers because they are anxious that their own authority shall be supreme in everything that belongs to the schools, and they are of opinion that the medical men may eventually undermine discipline. These apprehensions, however, seem to be unfounded, for a similar system has given satisfactory results in other towns, for instance, in Wiesbaden.—*London Lancet*, November 19.

An English Life-Table.—We have before us a recent report by Dr. Tattersall, the medical officer of health of Oldham, in which he has published a life-table for that city that will prove to be an additional evidence that the only completely trustworthy means of measuring the incidence of mortality in a given locality is gradually coming into more general use. This

is the seventh in the series of life-tables dealing with the mortality of different English towns during the decennium 1882-90. These, in the order of their appearance, so far as we can remember, were for Manchester, Brighton, Glasgow, London, Portsmouth and Haydock. According to *Public Health* for October, this latest report is a valuable addition to the list, especially as it is the only one except the life-table for Brighton which is constructed by the graphic method first applied to this purpose by Dr. Newsholme. Dr. Tattersall reproduces the description of the graphic method from the Brighton life-table, and his four plates are excellent practical illustrations of the method, which will be useful to others who decide to adopt this comparatively simple and very elegant method of obtaining the necessary data for a life-table. The method is not only very elegant, but accurate. Some of the main results of the life-table may be briefly mentioned. The expectation of life at birth in Oldham for males is 36.9 years, as compared with 34.7 in Manchester, 35.2 in Glasgow, and 43.6 in Brighton; while at the age of 10 the expectations of life, taking the towns in the same order, are 43.8, 42.7, 44.3 and 40.1 years. It is somewhat surprising to find, as Dr. Tattersall points out, that the expectation of life in Oldham is so little better than in Glasgow, in view of the facts that the population of Oldham is very well paid, well fed and well housed. Something may be due to the bleak and exposed position of the town, on the verge of the Pennines and built on clay. This view is supported by the excessive mortality among the old people, though all ages show an excess. Thus, among 100,000 males born, the number surviving in Oldham at 10 years of age is 67,157, as compared with 81,182 in the healthy districts; while at the age of 60 years there are only 27,308 left, against 52,507 in the healthy districts. Thus, while under favorable conditions more than half the children born are remaining alive at 60 years of age, in Oldham little more than a quarter survive.

Soil Disturbance and Malarial Fever.—The *Indian Medical Record* contains an article by Dr. Moore of Darjeeling, in which he contends that disturbance of the soil has come to be inculcated as the cause of malarial fever more frequently than is just and proper. In the extensive construction of canals and railroads frequent outbreaks of malarial fever occur, but is it not more likely that the cause is the waterlogged condition of the soil due to the subsoil drainage being interfered with, and not the soil disturbance? He cites two instances of outbreaks of malarial fever occurring in France, said to be caused by the extensive disturbance of the soil in constructing railways. When agricultural colonies are founded in Algiers these outbreaks occur. M. Armand, in his very able work, "*L'Algerie Medicale*," explains this as being due to the hardships endured from defective food, less refreshing sleep, exposure, more continued, and more directly the vicissitudes of the climate, to which the rising colony is exposed during the endemio-epidemic season. Considering that the fact of being in camp all the summer has a deteriorating effect upon the health of the men, even when no work is done, how much more will the effect be felt when all the fatigue attending the establishment of a colony has to be encountered. The work of installation and construction does not involve as much disturbance of the soil as the subsequent tillage of the land, yet it is during the first summer that the state of the men's health is least satisfactory. The same statement applied to the troops in the early days of Hong-Kong, and, as in Algiers, the greatest amount of fever did not correspond with the greatest amount of soil disturbance, a point indispensable if the two things are to stand in the relation of cause and effect, while in all cases the men were living under conditions of great exposure and badly housed. There are, then, three distinct classes in which all the cases where soil disturbance has been accused of causing malarial fever may be placed: 1. Where the disturbance of the soil has interfered with subsoil drainage and caused

a mareh or allied condition. 2. Where the outbreaks of fever have been coincident with works executed in the soil, but not due to the simple disturbance of the soil. 3. Where malarial fever has been caused by a specific poison, released and brought into evidence by the breaking up of the soil. Of course, falling into the first category there are plenty, but the author says it is a misnomer to speak of them as caused by soil disturbance. Of the second class there are also plenty; they belong to the type of a gentleman contracting the fever by digging in his garden. These cases are valueless. That malarial fever is caused in the manner specified in the third category there is not sufficient evidence to show.

Ambulance Work in London.—Dr. Heaton Howard, editor of *First Aid*, and the editor of *The Critic* (both of London) are making a struggle for a sensible and up-to-date ambulance service. The "little ward on wheels," as it is found in Paris, Vienna and several American cities, is unknown to London, except so far as the provision that has been made by the Metropolitan Asylum Board for the transportation of the infectious sick. The editor of *First Aid* advocates the establishment of several stations, having telephone connection, and supplied with either horse or electric motor wagons, having a surgeon and supplies suitable for the "first aid" of those who fall sick or become injured in the streets. "This kind of service," says *The Critic*, "is a matter that should come home to every citizen; for he is, if seized with sudden illness or the victim of accident, absolutely at the mercy of the first good-natured bungler who cares to seize upon him. Even if the guarantee of immediate skilled treatment in case of need should cost double the \$750,000 estimated as necessary for the preliminary organization, and treble the \$200,000 per annum suggested as the cost of maintenance and development, I do not think the average ratepayer would grudge the outlay. He already pays large sums for reading-rooms and museums which he does not always frequent, for parks which he seldom visits, for bands that do not irresistibly attract him, for baths which he does not often enter and many other public purposes, all good in their way, but each intimately affecting a section only of the population. An efficient ambulance service is as necessary as a gas-supply or a fire brigade; and no one can possibly supply it for himself. Thus it becomes a public concern." Another writer advocates an arrangement by means of which horse ambulance wagons are placed at the fire stations and worked by the fire brigade. Local conditions, as noted, unfavorably affect the adoption of any of the first three methods, and the fire brigade, from the nature of its duties, is the most suitable body to undertake the work; the firemen are already trained in the management of horses and in driving rapidly through the streets; the public are also accustomed to clearing the streets to make way for the brigade. The duties of the firemen are more intermittent and less onerous than those of the police: these duties are much less during the day, when accidents are more numerous. Their work also trains the firemen to act with more deliberation in an emergency, a great desideratum in dealing with an accident when surrounded by a crowd of excited people. "Ambulance wagons worked by fire brigades have been in use for some time in the following places among others: Sheffield, Leeds, Leicester, Halifax and York, and have rendered most satisfactory service." The expense, which is always a serious consideration in advocating new departures, is, in this case, not very formidable, as once the initial expense was accounted for, the cost of maintenance would be a very slight addition to the cost of the fire brigade. With regard to the powers of the corporation for incurring expense in this connection, we may cite the following opinion from a report of the chief constable of Liverpool on the police ambulance system recently inaugurated in that city: "It may be well in conclusion to mention that the corporation have been advised that they were legally entitled to take the action they have done, in-

asmuch as the removal of the sick and injured persons from the streets is an important portion of the duty of the police, and that charges for instruction to render them efficient may properly be met the authorities."

Camps on the Pacific Coast.—Sanitary and insanitary conditions at Camps Alger, Thomas, Tampa, and other places in the East, have become familiar by newspaper description and by testimony before the Commission on the Conduct of the War Department, but information from the Pacific Coast has rarely appeared in Eastern journals. The following from the annual report of Gen. H. C. Merriam, by Lieut. Col. I. V. D. Middleton, deputy surgeon-general, is of interest in showing medical conditions on the west side of the Continent:

The first camp on the Presidio Reservation (Camp Merriam) was well located as to soil, drainage and water-supply, the latter coming from one of the city mains and conducted by pipes to every part of the camp. The ground gradually slopes toward the bay and the drainage is excellent. The remaining troops of the expedition are now camped on this location. The weather during the early part of May was moist and chilly, unusually so, and the troops, being unaccustomed to camp life, soon contracted ailments incident to exposure, such as nasal and bronchial catarrh, diarrhea, etc., of which there were many cases. Unfortunately, the Oregon Volunteers brought with them a few cases of measles; these were isolated by being sent to the Presidio and Fort Mason post hospitals, but the disease spread quite rapidly and many cases were treated in the regimental tent hospitals, in consequence of which pneumonia supervened in a few cases, which were sent to the Presidio post hospital. As regiments were arriving daily, it was found necessary to secure a larger camping-ground, and I learned that the military authorities had, without consultation with any officer of the Medical Department as to hygienic conditions, selected the race track and the sand dunes adjoining, designating the encampment as Camp Merritt. It was an objectionable location, on account of its exposure to the wind and fog, its bad drainage and the constant drifting of the sand upon which the tents were pitched. The sinks were improperly located, being on a line with the company kitchens, and I may here remark that the Medical Department had nothing to do with this arrangement. The sand in the vicinity of the kitchens and around the tents, through the carelessness of the men, soon became polluted and was blown into the kitchens and mess tents. Soldiers were permitted to come to the city by the hundred every day, and many of them would return to camp late at night, some under the influence of liquor, riding on the "dummy" of the cable-cars, without overcoats and with their blouses unbuttoned. A large number of men of each regiment reported at sick call every morning, and a large proportion of them were admitted to the sick report, the prevailing ailments being nasal and bronchial irritation due to exposure to cold, and errors of digestion, diarrhea, etc., due to imprudence in eating and drinking. The Tennessee regiment brought measles to this camp, and it spread very rapidly. During the months of June, July and August, the reports on file show 660 cases of measles. This disease complicated most of the serious cases of pneumonia, numbering 145, from which 43 died. Typhoid fever made its appearance during the latter part of May, and 121 cases, with 13 deaths, are recorded for the months of June, July and August. The water was carefully examined from time to time, but was found to contain no bacteria of a pathogenic nature, the disease being propagated in all probability by the contamination of the food by the drifting of polluted sand, and may have been carried into the kitchens and tents by the flies that swarmed in and around the sinks, kitchens and tents. Thirty-six cases of cerebrospinal meningitis also occurred, with sixteen deaths.

The division hospital was established at Camp Merritt June 2, by Lieut.-Col. Henry Lippincott. A sufficient number of hospital tents, placed end-to-end, in pairs, were pitched on the sandy plain to accommodate 100 patients, but soon its capacity was increased for 200, and finally 300 patients. Major W. O. Owen, U. S. V., was in charge of this hospital. As serious cases of pneumonia and typhoid fever could not be properly sheltered and afforded an equable temperature under canvas, they were sent to the Marine and French Hospitals, close by, where they received excellent attention under the direction of Dr. James Gassaway, United States Marine-Hospital Service, and of the superintendent and physicians of the last-named hospital, due acknowledgement of their courtesy and valuable assistance having been expressed in letters to them by Dr. Owen and myself. On several occasions I urged the abandonment of the camp, and on July 21 the division hospital was re-

moved to the new barracks at Presidio, which were vacated by the troops of the garrison in order to accommodate the hospital. Here the patients were placed under far more favorable hygienic conditions than the canvas hospital can possibly afford, and the barracks were soon fitted up with all the comforts and conveniences that would facilitate the recovery of the sick. Wire netting and shades were put in the windows and all articles required for making it a first-class hospital were purchased and put in place. Thirty female nurses were employed, a sufficient number of physicians were contracted with, good cooks were obtained and, under the management of Major W. S. H. Matthews of the Fifty-first Iowa Vols., who has proved himself to be a good administrative officer, the hospital has been put in the very best order and condition obtainable under the circumstances, as the buildings were not constructed for hospital purposes and the ventilation is by no means perfect, the rooms are not of proper size or shape for wards, and the kitchens and mess-rooms are too far distant. The troops moved from Camp Merritt to the Presidio Reservation (Camp Merriam) in the following order: Fifty-first Iowa August 1, Twentieth Kansas August 5, First Tennessee August 18, Seventh California August 24, United States Infantry and Oregon Recruits August 27, and this was the final breaking up of Camp Merritt. This camp (Merriam) is now in excellent condition by being kept as clean as possible. The sinks are at suitable distances, emptied of their contents three times a week, and thoroughly disinfected twice daily; they are unobjectionable and not likely to cause sickness. Water is supplied from a city main and carried to every company, where there is a hydrant, the waste water being conducted off by means of drains. The cooking has been much improved, attention is given to bathing, and the men, better disciplined, are better able to take care of themselves. The sick list has been much diminished.

NECROLOGY.

T. H. HUZZA, M.D., Atlanta, Ga., died in New York December 9, as a result of an operation for appendicitis. Dr. Huzza was born in St. Louis, Sept. 12, 1863, and was graduated from the Jefferson Medical College in 1887, later doing special work in the Philadelphia Lying-in Charity Hospital, the Philadelphia Obstetrical Infirmary and the Pennsylvania School of Anatomy and Surgery, and was a gynecologist of some repute.

C. S. HOYT, M.D., Canandaigua, N. Y., died of pneumonia, December 13. Dr. Hoyt was born in Connecticut in 1822, received his degree of M.D. from the Geneva Medical College, and until the Civil War began practiced in Yates County, N. Y. He then enlisted in the 126th New York Volunteers, resuming his practice after the war. In 1867 he was elected to the Assembly, and in 1868 became Secretary of the New York State Board of Charities, since occupying that position.

JAMES LAWRENCE TYSON, M.D., University of Pennsylvania, 1838, died December 10, at his residence, Penllyn, Pa., in his 86th year. He was a descendant of the Celebrated Dr. Edward Tyson of London, whose descendant, Rinear Tyson, emigrated to Pennsylvania in 1683. Dr. Tyson was born in Philadelphia, Nov. 19, 1813. In 1854 he was elected professor of medicine and therapeutics in the Philadelphia College of Medicine. For several years he was physician to the Wills Eye Hospital. He was one of the founders of the Howard Hospital, and for many years one of its physicians. While in California he was surgeon-in-chief of a hospital in the northern gold region. He was a member of the Philadelphia College of Physicians before he moved to Montgomery County.

JOEL ALLEN, M.D., Burlington, Vt., a graduate of the Medical Department of the University of Vermont, Class of 1875, died at his home, December 6, aged 48 years. Dr. Allen was a member of the Vermont State Medical Society and the Burlington Clinical Society, and attending physician to the Home for Friendless Women and Home for Destitute Children.

A. S. BALDWIN, M.D., Jacksonville, Fla., died December 8, at the age of 88 years. He was born in New York; located in Jacksonville in 1838, and, at the age of 27 years, served as one of the defenders of the State in the Seminole War. His

early education was secured at Hobart College, Geneva, N. Y., from which he later received the degree of M.D., in 1838. In 1852 he was chosen to represent his county in the Florida State Legislature, and during the first session secured a charter for the Florida Central Railroad, later becoming president of the company organized. In 1858 he became State Senator and, as a member of that body, when the Civil War broke out strenuously opposed secession. He was for twenty years meteorologic correspondent for the Smithsonian Institute, the reports being the first scientific exhibition of Florida clinical literature. He was also corresponding member of the Boston Natural History Society and a member of the American Scientific Association, and is credited with having organized the first medical society in Florida, the Duval County Medical Society, and in 1873 the Florida State Medical Society, of which he was the first president.

DEATHS ABROAD.

VON KLAR of Prague, prominent in official circles and in his specialty, the care of the blind, is dead. He recently added a kindergarten to the Klar Institute for the Training of the Blind, founded by his father, to which he has devoted his best energies all his life.

LAWRENCE B. HOFF, M.D., died in his 40th year, October 9, of cardiac trouble, in Coast Hospital, Little Bay Ultimo, a suburb of Sydney, New South Wales. He was a son of the late Louise Bainbridge and the late Rear Admiral H. K. Hoff, U. S. N. Dr. Hoff was born and brought up in Germantown, Pa. He was his father's chief clerk when the Rear Admiral went to Havana in a United States warship several years ago. Dr. Hoff was a graduate of the University of Pennsylvania and practiced in Germantown. In New York City he was at one time librarian of the Twelfth Regiment New York State Militia. He went to Australia about five years ago. His death only recently became known to his friends through a returned unanswered letter.

SOCIETY NEWS.

First All-Russian Congress of Hydrology and Balneology.—This Congress opened in December, at St. Petersburg, under the most favorable auspices. The government appropriated 18,000 roubles, and members to the number of five hundred were given free first-class passage to and from the Congress at any time between November 20 and January 19.

Society of Washington Ophthalmologists and Otologists.—The December meeting of this society was recently held at the residence of Dr. Burnett, Dr. J. H. Bryan, vice-president, in the chair. Dr. Burnett read a paper, reporting a case of double nasal hemianopsia. The paper was discussed by Drs. Belt and Muncaster. Dr. Burnett also reported a case of severe injury of the ear, in which he performed a plastic operation, restoring the meatus auditorium externus, which was discussed by Drs. Bryan, Suter and Richardson. Dr. Charles W. Richardson read a paper on "Thrombosis of the Lateral Sinus," and reported a case upon which he had operated, ligating the jugular. The paper was discussed by Drs. Bryan, Burnett and J. J. Richardson.

MISCELLANY.

Examining Michigan Recruits.—"Don't this old injury hurt you when you attempt to run?" asked the examining surgeon of a candidate for enlistment. "Course it does. If yer looking for soldiers what's goin' to run, just count me out."—*Detroit Free Press*.

Sanatorium and Sanitarium.—Some uncertainty apparently exists as to the use and significance of these two words. A "sanatorium" is a place to which the sick go to get well. The word is derived from the Latin, *sanare*, to heal. "Sanitarium" is derived from the Latin, *sanitas*, health, and is considered by lexicographers an improper form for "sanatorium." There is no sound reason in having two words so nearly alike to convey the same idea, particularly when one exists without the sanction of authority. There is, therefore, good ground

for preferring the word "sanatorium" to its counterfeit "sanitarium."

Neurofibroma.—Menke reports a case of a large plexiform neurofibroma above the iliac crest, with others smaller on the neck and trunk. The patient was a vigorous young man, and nothing to explain the etiology was discovered. The head was free.—*Vienna Klin. Rund.*, November 27.

Don't Forget General Wood.—The *Sample Bag* asks, "Why did we beat Spain?" Because we are as strong as Sampson, we are as Schley as a fox, we are Miles long, we possess Merritt, we are Hobson's choice, what more Dewey want? . . . Only this—after the war is about over, the public in General Wood commit the care of the Cuban cities to a medical officer.

Sickness at Manila.—A correspondent of the New York *Herald* writes that sickness is on the increase among our troops at Manila, and adds that there is a rigid censorship as to the health conditions of the forces. The authorities do not censor private letters, and every man in every regiment may write in a much more alarmist fashion than would the newspaper correspondents, in any event. The soldiers must all see the great increase in the sick rate. The California regiment, which was the healthiest on the ground up to the time the city fell, has more than 150 men ill now, and has been compelled to secure a hospital of its own. There was no more room in the division hospital, which answered all the needs of the Spanish garrison before we came.

A Regrettable Omission.—The "printer's devil," or some other imp, is responsible for the oversight which led to the omission from the list of the newly elected officers of the American Public Health Association, in our report of the recent meeting of that body at Ottawa, Canada (vide *JOURNAL*, p. 988), of the name of the first vice-president for the year 1898-99—Dr. Henry Mitchell of Asbury Park, N. J., secretary of the State Board of Health of New Jersey, who was nominated for the office by the Advisory Council, without a rival candidate. The Association has honored itself by placing in its second office a sanitarian of such recognized merit and a health officer of such indomitable energy.

Sporozoa of Carcinoma.—Jurgens has succeeded in isolating from the mucus surrounding the neoplasm a micro-organism evidently belonging to the Gregarinidae in a number of cases of cancer of the stomach and one cancer of the bronchi, in which the air-passages were occluded, resulting in a collection of several generations of the sporozoa. It is much larger than the usual Gregarina, which he explains by the discovery of the fact that the micro-organism develops by the conjugation peculiar to this species, the two bodies blending to form a single large one which invades the cell until the shell of the cell, enclosing the micro-organism is all that is left of it. In this condition it resembles Miescher's tubes and Rainey's bodies, and he queries whether they may not be developed Gregarinidae. Further particulars are given in the *Klin. Therap. Woch.* of November.

Picrotoxin.—The conclusions of a recent study of the cocculus indicus and picrotoxin sent in to the Paris Académie de Médecine are that it is a dangerous poison, with an almost exclusively bulbar action, extremely slow of absorption and impregnation. It is the type of a bulbar convulsive, and has no direct effect upon the muscular fiber. The cardiac and respiratory manifestations depend upon the effect produced on medulla, although to this must be added a certain influence of the toxic substance on the nerves of the vegetative life. The central influence is also responsible for the salivary and intestinal hypersecretion observed in the dog, and the sudoral, salivary and lachrymal hypersecretion in the horse. The writers are extremely pessimistic in regard to its application in therapeutics.—*Bulletin*, November 15.

Ligation of Mesenteric Artery.—One of the rarest lesions in a "buffer accident" is a rupture of a branch of one of the mesenteric arteries. Such an accident occurred recently to a railway porter and he was admitted in a state of collapse into the London Royal Free Hospital. As the collapse seemed to diminish, operation was temporarily postponed, but later, as it was again increasing, it was decided to operate. Mr. Roughton opened the abdomen and found that one of the vasa intestini tenuis had been torn through about one inch from its origin. The distal end was bleeding freely and both ends were tied. The peritoneal cavity contained much blood, and the collapse was so extreme that saline transfusion was resorted to during the operation. The man has so far gone on well, and as ten days have now elapsed since the operation he will in all probability recover.—*Lancet*, October 22.

Meager Diet of Porto Rican Peasantry.—Dr. L. Amadeo, a physician resident in Porto Rico has made a careful report on the mental and physical condition of his fellow-islander. He was well qualified for undertaking the investigation, of which the summarized results were published in the New York journals, for he had both studied and practiced medicine in this country, and, being a Porto Rican by blood and birth, was not likely to see in his people defects that do not exist. What he did see was the effect of insufficient nutrition, extending through the whole working class, i. e., through the whole class, which, thanks to Spanish tariffs, was forced to live on roots and fruits. He implores his new rulers to avoid the murderous policy of their predecessors, and to put within the reach of the toiling thousands in Porto Rico the very food which so horrifies and disgusts the vegetarian monomaniacs. Meat, he says, is the remedy for wasted muscles and inactive brains. This is science; it is also common sense, but it will raise a howl of anger from the unfortunate people to whom the prohibition of good things seems to be the alternative to its abuse.—*New York Times*.

Absorption of Medicines in the Stomach.—Professor Moritz has been studying this subject with sodium salicylate, potassium iodid and pulverized charcoal administered before, during and after meals, investigating the results with the stomach-pump. They confirm the results already empirically established, although he was surprised at the rapidity with which water and any much diluted medicine passes out of the fasting stomach. A medicine given with milk, soup, wine, oil, etc., leaves the stomach much less rapidly; still slower if taken with the meals and so slowly after a meal that in case of hepatic colic, etc., occurring after a meal, morphia should be administered subcutaneously or per rectum. Fluids like soup, milk, oil, etc., cause a secretion of gastric juice and the motor function of the stomach is proportionately less as the secreting function is active. He confirms the benefits of a mucilaginous vehicle in protecting not only the stomach but the intestines from irritation, recommending that digitalis be thus administered, and mentions as progress Sahli's "glutoid capsules" made of gelatin hardened formaldehyde; practically insoluble in the gastric juice but readily dissolved by the pancreatic secretions.—*Munich Méd. Woch.*, November 29.

Suture of Auricle of the Heart.—E. Giordano reports the first case of suture of the left auricle, for a wound in which the knife had passed through the entire thickness of the wall. The condition of the patient rendered immediate intervention imperative and it was impossible to take all the desirable antiseptic precautions. The condition was satisfactory for a few days, but bloody pus then appeared in the drain and death ensued in two weeks. The query whether to lose time preparing the patient for the operation, or to take the chances of infection, is a vital one in such cases. The necropsy showed that the patient had recovered from the wound in his heart, that his purulent pleurisy was also on the way to recovery, and that he

succumbed to a later complication, abscesses in his right lung. The wounds in the auricle and in the pericardium were perfectly closed with a linear cicatrix. Farina of Rome sutured the right ventricle for a wound 5 to 6 millimeters in length, in 1896. The patient succumbed to broncho-pneumonia, but the heart wound was found cicatrized. Rehn's case was cured, also one reported by Parozzani, and another by Parlavacchio. Others that did not result in recovery are reported by Parozzani, Cappelen, Nicolai, Ninni, and Longo.—*Presse Méd.*; *Riforma méd.*, September 9 and 10.

Ankylostomum Duodenale.—About two years ago Drs. Ginn and Jacoby published (*Berlin Klin. Woch.*) certain observations which they had made on the presence of the *ankylostomum duodenale* and other parasites in the intestines of natives of India, and they arrived at two main conclusions: 1, when the ankylostomum has gained a hold in a native tribe in India, it spreads with great rapidity among the members of the tribe; and 2, it appears very probable that a person may have the ankylostoma in his intestine without being the subject of ankylostomiasis. In the summer of this year, 1898, the same observers had opportunities of examining the stools of several natives. Of the feces of eight natives of Ceylon, in eight the ova of *ankylostomum duodenale* were found, in seven those of *trichocephalus dispar*, and in six those of the *ascaris*. In the stools of six natives of Madras in six were observed the ova of *ankylostomum duodenale*, in six those of *trichocephalus dispar*, and in five those of *ascaris*, and in two of the Madras natives the larvae of *anguillula intestinalis* appeared. The first of the above proportions was therefore corroborated by the new investigations. As supporting the second of their conclusions, Drs. Ginn and Jacoby found that a large number of Asiatics and Africans in whose stools the ova of the ankylostomum were found exhibited no signs of anemia. Among certain tribes there seemed to exist a certain immunity from ankylostomiasis, but this immunity was limited in its range and by no means absolute in degree.—*London Lancet*, November 19.

Not Bound to Undergo Serious Operation.—Assuming that the injury complained of in the case of Kehoe against the Allentown & Lehigh Valley Traction Company was the result of a certain accident, the company, which was sued for damages, urged, in defense, that the injury was not of a permanent character, but one that could quickly and permanently be cured by proper medical treatment, namely, by a simple surgical operation, attended with no pain (if anesthetics were used or the patient etherized), and free from serious danger. However, in view of the evidence relating to the subject, the supreme court of Pennsylvania declares, Oct. 17, 1898, that there can not be any doubt of the correctness of the following instructions given the jury: 1. That, if they believed that the surgical operation, necessary to relieve or cure the plaintiff, was a serious or critic operation, necessarily attended with some risk of failure, then the plaintiff was not bound in law to undergo a serious and critic surgical operation, which would necessarily be attended with some risk of failure; and 2, that if they believed that such operation was dangerous and critic, and attended with risk of failure, she was privileged to exercise the liberty of choice, under such circumstances, as to whether suffering and feebleness, resulting from the injury, would be endured, or whether the surgeon's knife should be used.

Communications to Veterinarians Not Privileged.—A veterinary surgeon was asked what the owner of a certain horse had said as to his visiting the horse, and what the report was that had been received from the keeper as to the condition of the horse. To these questions the owner objected, as calling for privileged communications, and the objections were sustained by the trial court, as being in conflict with section 3643 of the Iowa Code

of 1873, prohibiting a disclosure of professional communications. The owner's counsel said in argument, "We have no case exactly in point to cite." And the supreme court of Iowa says, *Hendershott vs. Western Union Telegraph Company*, Oct. 22, 1898, that it thinks that none can be found to sustain the ruling. It holds that the reasons upon which the section referred to is based have no application whatever to a case of this character. Communications, it maintains, are privileged in certain cases for the reason that full and free communication in those cases is necessary and to be encouraged, but that these reasons do not apply to veterinary surgeons called to treat animals.

Donations for Medical Education.—The last report of the Board of Regents of New York summarizes the evidences of improvement in medical teaching in that State. There has been a remarkable increase in the material resources and property among the medical colleges and an increase, since 1898, of more than 100 per cent. in total property, and of nearly 100 per cent. in annual receipts. Since that time this great increase has grown still larger, especially in Greater New York. The University and Bellevue Hospital Medical College has the fine new building erected in 1897 by the faculty of the Bellevue Hospital Medical College. The College of Physicians and Surgeons, with the Vanderbilt Clinic, doubled in size by the additional gift, in 1895, of \$350,000, and the Sloan Maternity Hospital, greatly enlarged in 1897, now make the most complete plant in existence for scientific medical education. The Polhemus Memorial Clinic has been completed and thoroughly equipped since the last report, providing accommodations for the outpatient and medical school departments of the Long Island College Hospital. The intention of Mrs. Polhemus, that everything pertaining to the construction and equipment of this building should be of the most approved type, has certainly been carried out. The New York Medical College and Hospital for Women has just opened its handsome new building in West One Hundred and First Street. Last, but not least, \$1,500,000, the greatest amount ever devoted by one person at one time to purposes of medical instruction, has just been given to build, equip and endow the new medical department of Cornell University in New York City.

Unlawful Practice.—By the Nebraska statute any person not possessing the prescribed qualifications for the practice of medicine, surgery or obstetrics, or any person who has not complied with the provisions of the law relating thereto, who shall engage in the practice of medicine, surgery or obstetrics, or any of the branches thereof, shall be deemed guilty of a misdemeanor, etc. Any person shall be regarded as practicing medicine within the meaning of this statute who shall operate or profess to heal or prescribe for or otherwise treat any physical or mental ailment of another. But nothing therein is to be construed to prohibit gratuitous services in cases of emergency, or to apply to commissioned surgeons in the United States army and navy, or to nurses in their legitimate occupations, or to the administration of ordinary household remedies. Now, under this statute, the supreme court of Nebraska holds, in *State vs. Paul*, Oct. 20, 1898, any person within the exceptions prescribed, and not having complied with the requirements as to certificate and registration, who shall, for a remuneration, operate on, profess to heal, or prescribe for, or otherwise treat any physical or mental ailment of another, is liable to the penalties prescribed, although the operations were performed, and the medicines were administered and given, under the direction and charge of a licensed physician and surgeon. To make one liable to the penalties of the statute, the court further insists, it is not essential that at or before the treatment of the sick, he represented, claimed, or advertised himself to be a regular, legal or competent practitioner of medicine.

Discovery of a Roman Hospital.—Advices from Geneva to Paris are that the remains of a Roman hospital have just been discovered in Baden, in the Canton of Argovie, Switzerland. The ruins, both from an architectural and an antiquarian point of view, are said to be valuable and interesting, since they are the first traces of anything proving the existence of hospital arrangements among the Romans. Neither the remains of Pompeii nor Timgad have led antiquarians to suppose that the Romans ever devoted a building to the exclusive use of invalids. No Latin or Greek author, the Geneva press asserts, has left a description of such an establishment. Hippocrates, alone, in a passage which is very short and rather obscure, alludes to diseases which were treated in the Temple of Esculapius, but it is thought to be impossible to decide therefrom whether there were any places near the sanctuary especially set apart for treating diseases. The arrangement of the ruined structures at Baden leave no doubt as to the use for which they were built. The edifice is composed of fourteen small rooms, in which a large number of medical and surgical instruments, tweezers, tubes, knives for spreading plasters, spoons, measure glasses, cauterizers, ointment boxes, and the like were found. Antiquarians of Geneva who have visited the ruins assert that everything goes to show that this was the site of the hospital of the Fourth and Fifth Legions, which had their winter quarters in Baden.

Paternal Hereditary Syphilis.—An interesting lecture by Professor Fournier, on the subject of preventive treatment of paternal hereditary syphilis is reported in the *Semaine Méd.* of November 30, in which he states that when a fetus is threatened with paternal syphilis, the mother being healthy, it can be protected by specific treatment of the mother during her pregnancy, if commenced very early. After the fifth month it is useless. The method has been successful in such a large number of cases that the physician should consider it his duty to inaugurate it under such circumstances, even if he has to deceive the mother to conceal the father's condition. The mother-in-law is usually the worst feature of the case, he adds. Mercury should be the base of the treatment, but as the dosing is not for the mother, but for the fetus, minute doses are sufficient, if continued throughout the entire pregnancy. Sublimite sometimes affects the stomach in pills, and disgusto by its odor in a solution. He prefers pills of mercurous iodid, under the circumstances, with a daily dose of five centigrams, or even of twenty-five milligrams, suspending treatment for ten days after twenty days of treatment to rest the stomach, continuing it thus to the end of the pregnancy. Pinard prefers mercuric iodid as follows: Mercuric iodid .1 gm., potassium iodid 10 gm., aq. dest., or simple syrup, 250 gm., peppermint water 50 gm. Daily dose, two tablepoons of the solution or two desert-spoons of the syrup, in the middle of the meal. Barthélemy persuades the mother that an injection of serum once a month would benefit her, and thus injects grey oil, every thirty days. No unfavorable effects of this treatment of a healthy woman have been observed by any one. Pinard continues the treatment without interruptions. Others alternate the mercury with potassium iodid. Each method has been successful, and it is usually necessary to conform to individual circumstances in each case.

Acetylene Worry.—The *Independent* has a readable paper on the above title, minifying the causes for anxiety about the coming new illuminant, acetylene gas. The writer points out the great worriment that was caused about sixty six years ago over the proposed introduction of olefant gas. The timorous people of Philadelphia went so far as to publicly object to the disuse of oil in public lighting. They could not see what should prevent the flame at the jet from backing through the pipes to the house meter or even to the mains and the works' gasometer itself. Direful predictions were also made when

Stephenson proposed the locomotive. The canal and stage proprietors did not wish to be disturbed, and timidity also opposed progress. Stephenson had to talk of a very low speed, not greatly beyond that of the horse, or his bill would have failed in Parliament; but when an opponent in committee declared that even the cows would be driven mad by the glare of the red-hot engine chimney, he could not refrain from asking how they would know the chimney was not red with paint instead of heat. Only a few years ago the bicycle was opposed because horses (as was asserted) could not bear the sight of it, and if the "toy" was to be allowed in the streets every other vehicle must go. And now there is some trouble over acetylene gas and the carbide from which it is obtained. There are potencies of danger in both, and in what is there not? There is a choice in generators; there are ways of treating carbide; that substance is mischievous only as water touches it, and its affinity for moisture is so intense that it must be excluded from air or it slowly epoules; keep it in moderate quantities and securely sealed, and it brings no fire risk. The tallow dip displaced the pine knot, whale-oil displaced the tallow dip; "fluid" succeeded whale-oil; kerosene, gas and electricity have followed, in each step and each illuminant its own hazards, and each disturbing the timid. It is therefore inconsistent, and it will be futile, to resist acetylene. Underwriting must accept it in its turn and deal with it rationally.

Revocation of Certificates.—The Iowa statute designed to regulate the practice of medicine and surgery in that State provides for the issuing by the State Board of Medical Examiners of certificates, and authorizes the Board to revoke a certificate whose holder shall have been convicted of a felony committed in the practice of his profession or in connection therewith, or "for palpable evidence of incompetency." The statute does not prescribe the practice to be followed in cases instituted for the revocation of certificates. It may, when practicable, says the supreme court of Iowa, commenting on this in *Traer vs. State Board of Medical Examiners*, Oct. 24, 1898, follow somewhat the methods of the courts, yet, from the nature of the Board and the character of the duties it is required to perform, a more flexible practice than that allowable in the court must, of necessity, be followed in many cases. The person whose right it is to hold a certificate which has been issued to him should be given a fair opportunity to meet the charges and evidence against him. What would be "palpable evidence of incompetency," within the meaning of the statute, the supreme court further says, is not easy to define, although it must be sufficient to make plain and obvious the incompetency of the accused to practice as a physician and surgeon. In the absence of objection, it is of the opinion that evidence which tends to prove or disprove the competency of the accused may be considered, as affidavits, etc., even though it is not the best evidence which could be produced for that purpose. The provision of the statute which gives to the president or any member of the Board authority to administer oaths and take testimony in matters relating to their duties as examiners, if it applies to the revocation of certificates, the court also holds, is not exclusive, and does not prevent the consideration by the Board of Evidence not so taken. Finally, the court declares within the jurisdiction of the board to determine the competent and sufficiency of the evidence submitted to it, and if it errs in admitting evidence or in giving to it undue weight, the error can not be corrected by certiorari proceedings.

Gleanings.—Large piece of omentum torn out by ineane woman after opening her own abdomen exhibited recently before the Paris Soc. de Chirurgie. . . . Tumefaction of the submaxillary gland in one patient and a dermatitis in another from treatment with potassium iodid, reported by Danlos. . . . Case of severe diarrhea with incarcerated inguinal hernia, persisting until after the hernia was operated on. . . . Case of

chronic primary osteomyelitis of the spine reported by Israel in woman of 27 years (*Deutsche Med. Woch.*, November 24). . . . Fatal osteomyelitis caused by scraps of cloth from gunshot wound twenty-seven years previously. The scraps had evidently been encapsulated and the encapsulation broken by a violent muscular exertion (*Deutsche Med. Woch.*, July) . . . Ducrey's bacillus has been successfully isolated from soft chancres, resown and inoculated in man by Langlet, who invented a special medium for the purpose (*Presse Méd.*, November 12). . . . Neugenbauer observed a fourteen weeks' extra-uterine embryo extracted by vaginal celiotomy and embryotomy in which, when the breast was opened, the heart was found still rhythmically pulsating, and this automatic action continued for three hours (*Cbl. f. Gyn.*, No. 47). . . . Case of eczema of the lips caused by salol in a tooth-wash (*Deutsche Med. Woch.*, December 1). . . . Tailleurs reports fifty-four relapses in 234 herniotomies. He finds that there is least danger of a relapse after umbilic and greatest after femoral hernias. Also that suture of the pillars protects better than the Bassini, against relapses. The cases have been followed since 1890-94. . . . Partial resection of the cecum for localized tuberculous ulcerations. Recovery. Resection of the small intestine and surrounding omentum for chronic tuberculosis adhesences simulating a tumor. Recovery (*Cbl. f. Chir.*, December 3).

American Hypnotic Grasses.—The *New York Medical Journal*, November 12, refers to certain grasses of the genus *Stipa* that appear to have medicinal or poisonous properties. Some of the American species, *Stipa viridula*, found in some parts of the Southern States, especially in New Mexico and Texas, have recently been made the subject of investigation by Dr. A. Lyckhart Gillespie of Edinburgh. He was led to make the examination by information as to the unpleasant and alarming effects of the grass, locally termed "sleepy grass," on horses. The cowboys, he says, driving herds of cattle from one place to another over elevated prairie regions, are often astonished on waking in the morning, to find their horses, and perhaps their cattle also, unfit to proceed on the journey. "The traveler's horse," says Dr. Gillespie, "is a pitiable object. He stands with head and tail drooping, his form quivering, streams of sweat pouring down his sides, respiratory movements hurried and panting, his heart's action increased in force, judging by the evidence of palpation, while his excretion of urine is markedly increased, with symptoms of irritations and strangury accompanying its expulsion." He is incapable of movement and seems about to die, but so far as Dr. Gillespie's informant could say, actual death, either in horses or in cattle, is not known to have been caused by the grass. It seems to have no action on sheep. The acute symptoms pass off in about two days, but the general health of the animal is affected for some time. Dr. Gillespie has found it impracticable thus far to make a thoroughly satisfactory preparation from the grass for pharmacologic experiments. A weak mixture of hydrochloric or acetic acid and water was found to be the most effective menstruum for extracting the substance presumed to contain the active principle, but these acid extracts had to be neutralized partially before they could be used, and this partial neutralization precipitated much of the solid matter present. Alcoholic extracts also were employed. The author gives the details of four experiments, three on frogs and one on a rabbit. They confirmed the accounts of the narcotic and paralyzing action of the grass, and the animals seemed to be affected with hallucinations and great fright. The author also refers to the statement of Haeckel that another American species, *Stipa inebrians*, as well as the *Stipa sibirica* of the Russian steppes, has a similar action.

Toxicologic Relations of the Ptomaines.—The discovery, in 1870, by Selmi, of the first of the postmortem alkaloids revolution-

ized the medico-legal operations of the chemist. It made the process of detecting vegetable alkaloids a matter of so great delicacy that, for a time, it was thought it would thenceforth be impossible to prove poisoning from vegetable alkaloids by means of toxicologic investigations. Such an assertion was an exaggeration, the toxicologist who would feel himself at a loss in the presence of ptomains would be altogether incompetent. In fact, no special or very characteristic chemic reaction, as yet, enables us to distinguish the ptomains from vegetable alkaloids; nor is this in any way surprising, as it would be quite illogic to wish to establish between the two orders of alkaloids a difference which nothing can possibly justify, and which reminds us of the distinctions that were insisted on formerly as existing between the two kingdoms, animal and vegetable. The processes of decomposition, splitting up or synthesis, which determine the formation of ptomains are very certainly of the same order as those by virtue of which the vegetable cells fabricate quinin or strychnia. A certain number of the alkaloids most frequently met with in the organism have been equally often met with in vegetables—adenin and exanthin in tea leaves, for instance—and M. Pouchet states that there is little doubt on his part that at no distant date a continued alkaloid series will be found passing from the simplest ptomains as hydropyredic bases on to the most complex vegetable alkaloids. It is only by chemic reaction and physiologic experimentation taken together that we are enabled to succeed in identifying the alkaloids obtained toxicologically, with any particular vegetable alkaloids. No indication, however subtle, should be neglected in the double series of investigations. It was in consequence of attention to this, that, in the celebrated process of General Gibboni, Selmi succeeded in proving the innocence of the incriminated—by establishing the fact that the alkaloid obtained from viscera subjected to medico-legal examination, and which experts alleged was Delphinium, on a chemic reaction alone, in reality consisted of a ptomain which arrested the heart's action at *systole* instead of at *diastole* as in the characteristic action of the Delphinium alkaloid. The putrefactive coniaïn of Liebermann is distinguishable from the true coniaïn in that it is neither volatile nor toxic. It would be easy to multiply examples of that kind. Physiologic experimentation made also comparatively with the isolated products of viscera, and the alkaloids with which the chemic reactions obtained anteriorly seem to justify us, in fact, in disposing of any doubts. We ought consequently to obtain, under the same experimental conditions, results absolutely identic. The methods of physiologic experimentation known up to the present time are sufficiently delicate and exact to enable us to prove or disprove to a certainty deductions based on chemic analyses alone. We must of necessity hold that there never can be complete evidence of identity supplied by comparative chemic and physiologic examination of two alkaloids, unless they be constituted of one and the same substance. This is a fact of experiment which does not admit of disputes.—*The Scalpel*, October.

The Brunette Peoples of Europe.—Sergi has given, in *Science Progress*, the results of his study of the brunette races and their migrations to the Mediterranean belt. To his mind the origin of those races is a question of racial rather than linguistic migration. While admitting that Aryan speech among modern and historic peoples throws the burden of proof on anyone who essays to find an origin other than Aryan for those peoples, Sergi makes bold to assume that the race or races with which Aryan speech originated may have been at all times few in numbers, and may further have been long since extinct; and consequently that all the Aryan speaking races of historic times may have, at one time or another, learned Aryan speech, without acquiring more than a slight tincture of Aryan blood. The ground is thus left open for an examination of the question from a point of view primarily anthropologic, and based in the

first place on physical, viz., morphologic, criteria of natural kinship between the races to be examined. A survey of the whole Mediterranean shore line has led him to the conclusion that its earliest recognizable inhabitants and their descendants, who form the great mass of the present population, belong to a single closely connected group of races; that their earlier home is to be looked for in the former fertile interior of northern Africa, and not improbably in or near the upper valley of the Nile; and that the peninsulas of South Europe and Asia Minor have been peopled thence along several distinct routes which mainly follow the course of the pliocene land-bridges, or former land connections. The "Mediterranean race," thus described, has the following characteristics common to all its branches: The outer complexion is typically brown; brown skin, brown eyes, brown hair, abundant and always more or less wavy. It is thus equally distinct from the blonde white races which bound it on the north, and from the negro races of Africa. Modifications of the brown tint are found in all branches of the race, but are conceived to be due to intermixture either with the earlier aborigines or with subsequent intruders. The body is well-proportioned, the face oval, the nose rather narrow, the orbits wide and set horizontally, the forehead high and nearly vertic, the cheek-bones neither wide nor very high; the face not flattened, but if anything a little prominent in front; the neck long and well-rounded, and the features mobile and expressive. It is, in fact, the familiar brunette type which every one recognizes who has traveled to any extent along the Mediterranean. Determined by certain types of skull, the "Mediterranean race," appears, wherever it is found, as a collocation, more or less uniformly complete, of a number of such related types; and from this it is inferred that the race was already composite in the farthest area of origin to which it can be traced. This center is placed by Sergi in the upper valley of the Nile, on the ground that here, among the Abyssinians, Gallas and Somalis, the characteristic collocations of types are most completely exhibited; the dusky complexion of a large proportion of these races at the present day being discounted, partly by their long-continued exposure to a more tropic climate than any other branch of the race, and partly by the certainty of continuous infusion of a negroid strain from the south.—*Popular Science News*, November.

Columbus and His Medical Advisers.—It is said of the first of the voyages of Columbus, that out of his slender company, which all told numbered but 120 souls, there were two physicians, Master Alonzo, on board the caraval *Santa Maria*, and Master Juan, on board the *Pinta*. When Columbus returned to Spain, the last named officer remained behind, at Fort Navidad, and made one of the thirty eight victims who were massacred by the natives of San Domingo. The principal medical officer of the second expedition, which consisted of 1500 men, and sailed from Cadiz in the month of September, 1493, was Dr. Diego Alvarez Chanca of Seville, physician in ordinary to the King and Queen of Spain. In a report addressed to Ferdinand, Columbus referred to this officer in the following flattering terms: "I make a point of directing the attention of your Highness to the never-ending work wherewith Dr. Chanca is overwhelmed, in consequence of the heavy sick-roll, together with the dearth of provisions; but in spite of all difficulties he evinces the utmost zeal in everything that concerns his art, Your Highness having left me free to fix the amount of his remuneration (although it is perfectly certain that neither I nor anyone else in my position could give him a sum even approaching what he would gain on land), I have opened for him an annual credit of 50,000 maravedis." Dr. Chanca is given the credit of having cured Columbus of a malignant fever which had brought him to death's door, and he is also said to have been the first person to write a description of the new world, his contribution taking the form of a report to the Municipal Council of Seville. On his return to Spain he produced his

"Commentum Novum in Parabolis Divi Arnoldi de Villanova," which was published at Seville in 1514. But it was not solely to the members of the medical profession who sailed in his company that Columbus expressed his indebtedness. Paolo dal Pozzo Toscanelli, a famous physician and astrologer of Florence, gave him what is described as excellent advice regarding the possibility of reaching India from the West, and in order to simplify matters likewise presented him with a map showing the course he ought to steer. The value of the Florentine's counsel is open to question, but there was another less pretentious practitioner who undoubtedly was able to render the hero an inestimable service at a turning-point in his career. Discouraged by persistent opposition and well-nigh broken-spirited, Columbus had sought asylum in the convent of Santa Maria della Robida, in Andalusia, whereupon the prior, believing him to be mad, sent for Dr. Garcia Fernandez, an unassuming country surgeon from the neighboring hamlet of Palos de Moguer. Happily the village Galen was a man of discernment. He quickly perceived that his patient was no lunatic but a man of genius, and instead of consigning him to chains and a dungeon, after the fashion of the day, he not only restored him to health by his treatment but also won for him the good will of the prior, who furnished him with means and introduced him at Court. It is generally stated that Columbus died from gout, but Dr. de Ybarra disagrees with the authorities who are responsible for this diagnosis. In his opinion death was due to cardiac complication consequent on chronic rheumatism, and in support of this contention he adduces the testimony of several persons who aver that they saw the dying navigator during the last month of his life and that his body was enormously swollen from the chest downward.—*London Lancet*, November 9.

Examination Papers: Army Medical Department.—The following examples of written questions submitted by a recent examining board to candidates for appointment in the Medical Department in the Army will be of interest to many of our younger readers at this time:

ARITHMETIC.

1. Divide 15 by $\frac{1}{15}$. Multiply by $\frac{1}{45}$, and subtract $\frac{25}{12}$ from the product.
2. Multiply .009 by 90. Divide .009 by 90.
3. A garrison of 450 soldiers have rations for five months only. How many should be detached to make the rations last nine months?
4. Give the metric equivalent of 3 grains: 3 fluidrachms; 3 pounds; 3 quarts; 3 yards.
5. Name and describe briefly four principal kinds of triangles.
6. Which is the larger and by how much, a box 10 x 8 x 6 feet, or a cube of 8 feet?

GEOGRAPHY.

1. Bound the State of Tennessee. What are its principal rivers? Name its capital and its largest cities.
2. Through what States does the Appalachian chain of mountains extend? What and where are the highest elevations?
3. In going from Duluth to Quebec by water, through what lakes and river and canals, and by what States would you pass?
4. What rivers form the principal drainage system of the United States, and into what bodies of water do they flow?
5. What countries border on the Mediterranean Sea.
6. Where is India? How is it governed? Name its principal rivers and cities.

HISTORY AND LITERATURE.

1. Who was Julius Caesar? When, approximately, did he live? For what was he distinguished?
2. What was Queen Elizabeth's claim to the throne of England? About when did she live? Mention the most important events and writers of her reign.
3. What nations made the earliest settlements in North America, and where were they located?
4. What were the most important events in the career of Benjamin Franklin? When, approximately, did he live?
5. What historians has the United States produced? Mention at least one work of each.

6. Who were the authors of the following works: "Don Quixote," "Faust," "Les Miserables," "The Inferno," "Childe Harold's Pilgrimage," "Paradise Lost," "Evangeline," "Scarlet Letter," "The Autocrat of the Breakfast Table," "The Spy," "Legend of Sleepy Hollow?"

CHEMISTRY.

1. How may hydrogen be obtained? State its color and odor, and its weight as compared with an equal volume of atmospheric air under similar conditions. What is meant by "similar conditions" in the last sentence?
2. How would you obtain a jarful of carbon dioxide for experimental purposes? How would you recognize that the jar contained carbon dioxide? What is its chemical formula; its molecular weight?
3. What is that which is known popularly under the name of "laughing gas"? What is the formula? How is it prepared?
4. What is an anhydride? Give the names and chemical formulas of two anhydrides.
5. How is sal ammoniac prepared commercially?
6. What chemical action takes place when copper turnings are heated with sulphuric acid?
7. What are the principal ores of zinc? What is the formula for zinc chloride; for zinc sulphate?
8. What is glycerin chemically?
9. Explain the chemical action which takes place when gunpowder is exploded.

PHYSICS.

1. Does a given body weigh more near the poles of the earth or near the equator? Give an explanation of the fact.
2. Explain the principle of the hydraulic press.
3. What is meant by a compensating pendulum?
4. What is the dew point? How may it be determined?
5. What are the dark lines of the solar spectrum occasioned by?
6. An observer saw the flash of an explosion, and ten seconds later the sound reached his ears: What was his distance, approximately, from the locality of the explosion?
7. Describe a cell of an electric battery.

ANATOMY.

1. Describe the origin, insertion and action of the several muscles attached to the scapula.
2. Describe the origin, courses, branches, distribution and relations to other organs of the nerves of the arm and forearm.
3. Describe the anatomy of the palm of the hand.
4. Describe the origin, course, branches, distribution and relation to other organs of the internal pudic artery.
5. Describe the anatomy of the ankle-joint.

PHYSIOLOGY.

1. Tell what you know about the cerebral localization of the functions of motion and locate some of the so-called motor areas.
2. What are the functions of the thyroid gland and the consequences of its removal?
3. What is the composition of atmospheric air and of expired air?
4. Give a list and a short description of some of the animal albuminoids.
5. What is urea? What is the normal quantity in proportion to body weight? How is it estimated?

SURGERY.

1. Give in detail the preparation and several following steps of a so-called aseptic surgical operation.
2. What is the nature and origin of pus? What is sepsis and also antiseptics?
3. Describe Chopart's amputation through the foot, with diagram.
4. Give the points of diagnostic differentiation in cases of lupus ulceration, syphilitic ulceration and epitheliomatous ulceration.
5. Describe the different methods of procedure for the reduction of luxations of the head of the femur.

HYGIENE.

1. What is the normal amount of CO₂ in the atmosphere; how much of this gas is considered admissible in inhabited apartments, and how is the amount determined?
2. What amount of cubic-air space per bed would you consider a suitable allowance in a hospital ward?
3. What substances in well or river water indicate by their presence, contamination from excreta or other organic matter of animal origin.
4. How is the hardness of water eliminated and to what is it due?

5. What are the constituent alimentary substances in milk, and how does cow's milk differ from human milk?
6. What vegetable products used as food contain the largest proportion of carbohydrates and what the largest proportion of proteids?
7. What parasites dangerous to man may be present in the flesh of animals used as food?
8. How would you disinfect the excreta of patients sick with cholera or typhoid fever?

PATHOLOGY AND BACTERIOLOGY.

1. What are the different stages of exudative inflammation and what the products of such inflammation?
2. What are the causes of thrombosis, what the composition and varieties of thrombi, and what changes may they undergo?
3. What pathologic changes are found in the spinal cord in posterior spinal chlorosis?
4. What changes occur in the liver as a result of chronic interstitial hepatitis?
5. What bacteria are commonly found attached to the diseased valves in mycotic endocarditis?
6. What are the morphologic and biologic characters of the bacillus of diphtheria, and what are the evidences of its etiologic relation to this disease?

THERAPEUTICS, MATERIA MEDICA, TOXICOLOGY.

1. By what various agents may antipyresis be produced? Give an example of each class of antipyretics and state how it acts.
2. In a case of typical acute pleurisy state the indications for treatment in its several stages and how you would meet them.
3. What is salol? Give its physiologic action and therapeutic use?
4. Give the source and therapeutic uses of cocaine, the dose in each case, and its dangerous effects.
5. With what condition is poisoning from opium most likely to be confounded? How would you make a diagnosis and how treat such a case?
6. What are the poisonous effects of the lead salts? How is their presence detected? State briefly your plan of treatment.

PRACTICE OF MEDICINE.

1. Give an account of the etiology, symptoms, physical signs and differential diagnosis of lobular pneumonia.
2. Give an account of the etiology, physical signs and treatment of empyema.
3. Give an account of the etiology, symptoms, differential diagnosis and treatment of dilatation of the stomach.
4. What are the causes and symptoms of intestinal obstruction and what is the treatment?
5. What are the causes and results of mitral stenosis and how would you recognize this condition?
6. Give the differential diagnosis between smallpox and measles.

OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

1. Describe briefly the usual mechanism of a breech presentation; what dangers are to be guarded against and what difficulties to be met.
2. Under what circumstances is premature delivery demanded and how would you perform it?
3. What symptoms would lead you to suspect the presence of a uterine fibroid? State how an exact diagnosis can be made in such cases.
4. What measure preventive or remedial would you use in a case of puerperal convulsions?
5. What early symptoms indicate probable onset of the chief eruptive fevers in children? In which does temperature range highest; which has the shortest period of incubation, of invasion, of eruption.

Foreign Bodies in the Abdominal Cavity.—Dr. T. S. Bullock has handled this subject quite adroitly in a paper read before one of the Louisville societies. He has been enabled to corral over fifty cases, chiefly American in origin, and largely unreported in the journals, from which experience he deduces the doctrine "Let the surgical Pharisee who is tempted to say, 'I am holier than thou,' beware." In consonance with this teaching is presented the remarkable experience of an honored surgeon in New York City, which was somewhat as follows: Early in his practice, this surgeon had a lesson that led him to adopt every well-considered precaution against leaving any foreign bodies in the abdominal cavity after operating. On one occasion, so careful had he become, he thrice reopened the wound in order to search for a missing sponge, which turned up in a pail.

After this he made it a point never to put a fresh sponge in the cavity until its predecessor had been removed, and then, if possible to keep it under his own eye. He went on in this way for seven or eight years, and says he had begun to think this accident would never happen in his practice; but it did, and when he least expected it. In a simple salpingotomy four gauze pads were used, and although all were accounted for by a most conscientious nurse and two assistants before the sutures were tied, one was left behind. Subsequently a mural abscess developed at the upper angle of the wound, and on opening it the pad presented itself and was removed, the patient making a good recovery. Dr. Bullock reports his own case which hinged on the losing of a large-sized aseptic gauze pad due to a miscount of the pads by a trusted nurse. This misadventure made necessary an operation for the removal of the pad; the patient recovered. Regarding the prognosis in these accidents, the author of the paper finds that much will depend: 1. On whether and when the accident is discovered. If the wound has been closed, it should be reopened and the foreign body removed. If not more than twenty-four or forty-eight hours have elapsed, the case will in all probability proceed as if the accident had not occurred. 2. If not discovered so soon, whether a correct diagnosis is subsequently made. If so, the body should be removed at once, this procedure giving the patient the best possible chance and saving tedious convalescence and much danger and discomfort. If the diagnosis is not made, Nature takes charge of the case, and unless the foreign body is septic, her efforts are generally crowned with success. 3. Whether the body left is aseptic or not. The case just cited shows what methods are employed when the object overlooked is aseptic and nature is not at once overwhelmed. Twenty-one cases reported by Dr. Wilson in 1884, which occurred in pre-aseptic days, with a single exception, died. If the operation is aseptic, the chances of the patient are by no means hopeless as to ultimate recovery. The larger number of the reported cases have ultimately expelled the foreign body and made a good, if slow, recovery. A. McLauren reported seven in 1896, with only one death. 4. If the body left is an instrument, as a forceps or clamp, unless discovered and immediately removed, death invariably ensues, and if found at all, it is at the postmortem. Their weight is too great a handicap for even so good a jockey as Nature, and she is unable to transport them to a suitable place for safe expulsion. I will now report my own case, which affords an additional opportunity for observing our good friend Nature's methods, and call attention to several important diagnostic points, should the accident not be promptly discovered and remedied. The author quotes a remark made by Dr. Coe, who said regarding the inevitable tendency of these accidents to go unreported: "We must not be surprised that only a small proportion of the cases are reported, as it is natural for us to seek to conceal our errors and failures, forgetting that these would be more valuable contributions to medical literature than a long series of successes; and that if we can learn from the mistakes of others, the experience is less costly than when gained by our own mishaps." Up to the present time those of our profession thus philanthropically inclined are in a very small minority. Our brother surgeon is too prone to think aloud some criticism that subsequently makes large drafts on his ingenuity to enable him to escape being arrayed against his friend on the witness stand in the suit filed because of his adverse comment. All hail the day when the medical profession shall face the world as a unit and not as at present—every man for himself, and the devil take the other fellow.—*Am. Prac. and News*, October 15.

Detroit.

APPOINTMENTS.—Dr. J. E. Clark has been appointed by the auditors of Wayne County as the official chemist, at a salary of \$1000 a year. It will be his duty to make all analyses of material in cases where death by poison is suspected and chemic analysis of stomach contents is ordered by the court.

HEALTH REPORT.—For the week ending December 17, there were reported: Deaths, 75; under 5 years, 24; births, 55, male, 29, female, 26; number of cases of diphtheria, last report, 14, new cases 17, recoveries 9, deaths 1, now sick, 21; scarlet fever, last report, 42, new cases 18, recoveries, 14, no deaths, now sick, 46; smallpox, 1 case.

Cincinnati.

A TIMELY GIFT.—The University of Cincinnati, of which the Ohio Medical College is the medical department, has recently been the recipient of a most valuable library of books from Mr. William A. Proctor. Mr. Proctor purchased outright "The Robert Clarke Collection" of over six thousand volumes, covering a large variety of subjects, and which is estimated to be worth more than \$100,000. The collection was given practically without condition. It is a most timely gift, as the new library building donated by Van Wormer will soon be up, and this gift will doubtless stimulate others to contribute. Indeed, in a discussion of the Board, convened to take action on Mr. Proctor's magnificent donation, several enthusiastic members spoke freely of large gifts of books to be made in the near future.

SMALLPOX.—An epidemic of smallpox recently broke out in Wyoming, but a few miles from Cincinnati. Dr. Probst, secretary of the Ohio State Board of Health, and Dr. Byron Stanton, Cincinnati member, diagnosed the cases as smallpox, however, of a very mild type. It was decided by these officials, in consultation with the local health officer, that a general quarantine would be disastrous to business interests, so that a local quarantine of the districts and houses to which the disease has been confined, preventing ingress and egress of all who had been exposed, was substituted. As regards Cincinnati, Health Officer Tenney directed a general vaccination among school children in both the common and parochial schools, all who are unable to afford the expense to be vaccinated by the district physicians, free of charge. It is supposed that the contagion was conveyed from the cases at Loveland.

DR. PERCY ASHBURN successfully passed the examination for assistant-surgeon, U. S. A., and was one of three successful candidates in a class of twenty five.

Louisville.

KENTUCKY SCHOOL OF MEDICINE.—Some weeks ago it was noticed in these columns that Judge Barker had granted Drs. Woody and Kelly, respectively dean and professor in the Kentucky School of Medicine, an injunction restraining Drs. Cochran and Boyd from claiming to be professors in the school, and Dr. W. H. Wathen from claiming to be dean. At a meeting of the Board of Regents of the College, held a short time before, it had been decided that Drs. Woody and Kelly should be removed; they at once took this action and elected Drs. Cochran and Boyd in their places and Dr. Wathen as dean to succeed Dr. Woody. Because of the fact that Judge Miller, before whom the case was docketed, had been an attorney for Dr. Wathen, and his law partners were at present his attorneys, Drs. Woody and Kelley asked that he not hear the case, and through their attorney attempted to swear him off the bench. He refused to vacate the bench, and the case as to whether the injunction should be dissolved or not was submitted on briefs, and he has just handed down his opinion, which is a voluminous one. He dissolves the injunction granted Drs. Woody and Kelly, and dismisses their petition. The attorney for Drs. Woody and Kelly at once filed a motion of appeal, and Judge Miller will hear an argument as to whether the injunction shall be continued in force pending the appeal. The charter of the Kentucky School conferred upon the Board of Regents the power to remove professors. The plaintiffs claimed that by an amendment of March 25, 1886, the Legislature modified this power to the extent of requiring a majority of the members of the faculty to request the removal. That amendment also named the professors of the school, among them being Drs. Woody and Kelly. On August 1, last, as above mentioned, the Board of Regents, without the action of the faculty, removed Drs. Woody and Kelly from their professorships, and elected Dr. Wathen as dean. The latter's claim to a professorship was not questioned, only his claim to being dean. Judge Miller held that the amendment of 1886 was not accepted by the Kentucky School of Medicine and was of no effect, and that the Board of Regents had acted within the powers conferred by the original charter.

DENTISTS.—The Falls City Dental Club and the Louisville Odontological Society held their first joint meeting on December 10 at the building of the Louisville College of Dentistry. About fifty-five members of the two organizations were in attendance. A number of papers were read and at the conclusion an enjoyable banquet was given. The officers of the two organizations were as follows: Odontological Society, J. W. Clark, president; P. R. Feigel, vice-president; F. J. Gardner, secretary-treasurer. Dental Club: C. G. Edwards, president; E. M. Kettig, vice president; C. K. Runyon, secretary-treasurer.

THE PUBLIC SERVICE.

Movements of Army Medical Officers.—To Manila, P. I.: Lieut. Irving W. Rand, asst.-surgeon U. S. A., from Ft. Duchesne, Utah. To military posts: To Columbus Bks., Ohio, Capt. Jefferson D. Poin-dexter, asst.-surgeon U. S. A., from Ft. Hamilton, N. Y., to Jefferson Bks., Mo., Acting Asst.-Surgeon Llewellyn P. Williamson from St. Louis, Mo.; to Ft. Riley, Kan., Acting Asst.-Surgeon F. A. Disney from Washington, D. C.; to Ft. Sam Houston, Texas, Major Charles L. Heizmann, surgeon U. S. A., from Ft. Adams, R. I.

To regiments: Lieut. Leigh A. Foller, asst.-surgeon U. S. A., to the Second U. S. Artillery at Savannah, Ga.; Acting Asst.-Surgeons Elmer Anderson Dean and Arthur W. Smith to the Third U. S.
